# Working Draft, Standard for Programming Language C++

Note: this is an early draft. It's known to be incomplet and incorrekt, and it has lots of bad formatting.

# Contents

# 1 Scope

[intro.scope]

- <sup>1</sup> This document specifies requirements for implementations of the C++ programming language. The first such requirement is that they implement the language, so this document also defines C++. Other requirements and relaxations of the first requirement appear at various places within this document.
- <sup>2</sup> C++ is a general purpose programming language based on the C programming language as described in ISO/IEC 9899:2011 *Programming languages — C* (hereinafter referred to as the *C standard*). C++ provides many facilities beyond those provided by C, including additional data types, classes, templates, exceptions, namespaces, operator overloading, function name overloading, references, free store management operators, and additional library facilities.

## 2 Normative references

[intro.refs]

- <sup>1</sup> The following documents are referred to in the text in such a way that some or all of their content constitutes requirements of this document. For dated references, only the edition cited applies. For undated references, the latest edition of the referenced document (including any amendments) applies.

- (1.1) — Ecma International, *ECMAScript Language Specification*, Standard Ecma-262, third edition, 1999.
- (1.2) — ISO/IEC 2382 (all parts), *Information technology — Vocabulary*
- (1.3) — ISO/IEC 9899:2011, *Programming languages — C*
- (1.4) — ISO/IEC 9945:2003, *Information Technology — Portable Operating System Interface (POSIX)*
- (1.5) — ISO/IEC 10646-1:1993, *Information technology — Universal Multiple-Octet Coded Character Set (UCS) — Part 1: Architecture and Basic Multilingual Plane*
- (1.6) — ISO/IEC/IEEE 60559:2011, *Information technology — Microprocessor Systems — Floating-Point arithmetic*
- (1.7) — ISO 80000-2:2009, *Quantities and units — Part 2: Mathematical signs and symbols to be used in the natural sciences and technology*

<sup>2</sup> The library described in Clause 7 of ISO/IEC 9899:2011 is hereinafter called the *C standard library*.<sup>1</sup>

<sup>3</sup> The operating system interface described in ISO/IEC 9945:2003 is hereinafter called *POSIX*.

<sup>4</sup> The ECMAScript Language Specification described in Standard Ecma-262 is hereinafter called *ECMA-262*.

---

<sup>1</sup>) With the qualifications noted in ?? through ?? and in ??, the C standard library is a subset of the C++ standard library.

### 3 Terms and definitions

[intro.defs]

- <sup>1</sup> For the purposes of this document, the terms and definitions given in ISO/IEC 2382-1:1993, the terms, definitions, and symbols given in ISO 80000-2:2009, and the following apply.
- <sup>2</sup> ISO and IEC maintain terminological databases for use in standardization at the following addresses:
  - (2.1) — ISO Online browsing platform: available at <http://www.iso.org/obp>
  - (2.2) — IEC Electropedia: available at <http://www.electropedia.org/>
- <sup>3</sup> ?? defines additional terms that are used only in ?? through ?? and ??.
- <sup>4</sup> Terms that are used only in a small portion of this document are defined where they are used and italicized where they are defined.

#### 3.1

[defns.access]

##### access

⟨execution-time action⟩ read or modify the value of an object

#### 3.2

[defns.argument]

##### argument

⟨function call expression⟩ expression in the comma-separated list bounded by the parentheses (??)

#### 3.3

[defns.argument.macro]

##### argument

⟨function-like macro⟩ sequence of preprocessing tokens in the comma-separated list bounded by the parentheses (??)

#### 3.4

[defns.argument.throw]

##### argument

⟨throw expression⟩ operand of throw (??)

#### 3.5

[defns.argument.templ]

##### argument

⟨template instantiation⟩ *constant-expression*, *type-id*, or *id-expression* in the comma-separated list bounded by the angle brackets (??)

#### 3.6

[defns.block]

##### block

wait for some condition (other than for the implementation to execute the execution steps of the thread of execution) to be satisfied before continuing execution past the blocking operation

#### 3.7

[defns.cond.supp]

##### conditionally-supported

program construct that an implementation is not required to support [*Note 1 to entry*: Each implementation documents all conditionally-supported constructs that it does not support. — *end note*]

**3.8** [defns.diagnostic]**diagnostic message**

message belonging to an implementation-defined subset of the implementation's output messages

**3.9** [defns.dynamic.type]**dynamic type**

$\langle\text{glvalue}\rangle$  type of the most derived object (??) to which the glvalue refers [*Example*: If a pointer (??)  $p$  whose static type is “pointer to class B” is pointing to an object of class D, derived from B (??), the dynamic type of the expression  $*p$  is “D”. References (??) are treated similarly. —*end example*]

**3.10** [defns.dynamic.type.prvalue]**dynamic type**

$\langle\text{prvalue}\rangle$  static type of the prvalue expression

**3.11** [defns.ill.formed]**ill-formed program**

program that is not well-formed (??)

**3.12** [defns.impl.defined]**implementation-defined behavior**

behavior, for a well-formed program construct and correct data, that depends on the implementation and that each implementation documents

**3.13** [defns.impl.limits]**implementation limits**

restrictions imposed upon programs by the implementation

**3.14** [defns.locale\_specific]**locale-specific behavior**

behavior that depends on local conventions of nationality, culture, and language that each implementation documents

**3.15** [defns.multibyte]**multibyte character**

sequence of one or more bytes representing a member of the extended character set of either the source or the execution environment

[*Note 1 to entry*: The extended character set is a superset of the basic character set (??). —*end note*]

**3.16** [defns.parameter]**parameter**

$\langle\text{function or catch clause}\rangle$  object or reference declared as part of a function declaration or definition or in the catch clause of an exception handler that acquires a value on entry to the function or handler

**3.17** [defns.parameter.macro]**parameter**

$\langle\text{function-like macro}\rangle$  identifier from the comma-separated list bounded by the parentheses immediately following the macro name

<b>3.18</b>	[ <b>defns.parameter.templ</b> ]
<b>parameter</b>	
⟨template⟩ member of a <i>template-parameter-list</i>	
<b>3.19</b>	[ <b>defns.signature</b> ]
<b>signature</b>	
⟨function⟩ name, parameter type list (??), enclosing namespace (if any), and trailing <i>requires-clause</i> (??) (if any)	
[ <i>Note 1 to entry:</i> Signatures are used as a basis for name mangling and linking. — <i>end note</i> ]	
<b>3.20</b>	[ <b>defns.signature.templ</b> ]
<b>signature</b>	
⟨function template⟩ name, parameter type list (??), enclosing namespace (if any), return type, <i>template-head</i> , and trailing <i>requires-clause</i> (??) (if any)	
<b>3.21</b>	[ <b>defns.signature.spec</b> ]
<b>signature</b>	
⟨function template specialization⟩ signature of the template of which it is a specialization and its template arguments (whether explicitly specified or deduced)	
<b>3.22</b>	[ <b>defns.signature.member</b> ]
<b>signature</b>	
⟨class member function⟩ name, parameter type list (??), class of which the function is a member, <i>cv-qualifiers</i> (if any), <i>ref-qualifier</i> (if any), and trailing <i>requires-clause</i> (??) (if any)	
<b>3.23</b>	[ <b>defns.signature.member.templ</b> ]
<b>signature</b>	
⟨class member function template⟩ name, parameter type list (??), class of which the function is a member, <i>cv-qualifiers</i> (if any), <i>ref-qualifier</i> (if any), return type (if any), <i>template-head</i> , and trailing <i>requires-clause</i> (??) (if any)	
<b>3.24</b>	[ <b>defns.signature.member.spec</b> ]
<b>signature</b>	
⟨class member function template specialization⟩ signature of the member function template of which it is a specialization and its template arguments (whether explicitly specified or deduced)	
<b>3.25</b>	[ <b>defns.static.type</b> ]
<b>static type</b>	
type of an expression (??) resulting from analysis of the program without considering execution semantics	
[ <i>Note 1 to entry:</i> The static type of an expression depends only on the form of the program in which the expression appears, and does not change while the program is executing. — <i>end note</i> ]	
<b>3.26</b>	[ <b>defns.unblock</b> ]
<b>unblock</b>	
satisfy a condition that one or more blocked threads of execution are waiting for	

**3.27****[defns.undefined]****undefined behavior**

behavior for which this document imposes no requirements

[*Note 1 to entry:* Undefined behavior may be expected when this document omits any explicit definition of behavior or when a program uses an erroneous construct or erroneous data. Permissible undefined behavior ranges from ignoring the situation completely with unpredictable results, to behaving during translation or program execution in a documented manner characteristic of the environment (with or without the issuance of a diagnostic message), to terminating a translation or execution (with the issuance of a diagnostic message). Many erroneous program constructs do not engender undefined behavior; they are required to be diagnosed. Evaluation of a constant expression never exhibits behavior explicitly specified as undefined (??). — *end note*]

**3.28****[defns.unspecified]****unspecified behavior**

behavior, for a well-formed program construct and correct data, that depends on the implementation

[*Note 1 to entry:* The implementation is not required to document which behavior occurs. The range of possible behaviors is usually delineated by this document. — *end note*]

**3.29****[defns.well.formed]****well-formed program**

C++ program constructed according to the syntax rules, diagnosable semantic rules, and the one-definition rule (??)

## 4 General principles [intro]

### 4.1 Implementation compliance

[intro.compliance]

- <sup>1</sup> The set of *diagnosable rules* consists of all syntactic and semantic rules in this document except for those rules containing an explicit notation that “no diagnostic is required” or which are described as resulting in “undefined behavior”.
- <sup>2</sup> Although this document states only requirements on C++ implementations, those requirements are often easier to understand if they are phrased as requirements on programs, parts of programs, or execution of programs. Such requirements have the following meaning:
  - (2.1) — If a program contains no violations of the rules in this document, a conforming implementation shall, within its resource limits, accept and correctly execute<sup>2</sup> that program.
  - (2.2) — If a program contains a violation of any diagnosable rule or an occurrence of a construct described in this document as “conditionally-supported” when the implementation does not support that construct, a conforming implementation shall issue at least one diagnostic message.
  - (2.3) — If a program contains a violation of a rule for which no diagnostic is required, this document places no requirement on implementations with respect to that program.

[*Note*: During template argument deduction and substitution, certain constructs that in other contexts require a diagnostic are treated differently; see ???. — *end note*]

- <sup>3</sup> For classes and class templates, the library Clauses specify partial definitions. Private members (??) are not specified, but each implementation shall supply them to complete the definitions according to the description in the library Clauses.
- <sup>4</sup> For functions, function templates, objects, and values, the library Clauses specify declarations. Implementations shall supply definitions consistent with the descriptions in the library Clauses.
- <sup>5</sup> The names defined in the library have namespace scope (??). A C++ translation unit (??) obtains access to these names by including the appropriate standard library header (??).
- <sup>6</sup> The templates, classes, functions, and objects in the library have external linkage (??). The implementation provides definitions for standard library entities, as necessary, while combining translation units to form a complete C++ program (??). Two kinds of implementations are defined: a *hosted implementation* and a *freestanding implementation*. For a hosted implementation, this document defines the set of available libraries. A freestanding implementation is one in which execution may take place without the benefit of an operating system, and has an implementation-defined set of libraries that includes certain language-support libraries (??).
- <sup>8</sup> A conforming implementation may have extensions (including additional library functions), provided they do not alter the behavior of any well-formed program. Implementations are required to diagnose programs that use such extensions that are ill-formed according to this document. Having done so, however, they can compile and execute such programs<sup>8</sup>. Each implementation shall include documentation that identifies all conditionally-supported constructs that it does not support and defines all locale-specific characteristics.<sup>3</sup>

2) “Correct execution” can include undefined behavior, depending on the data being processed; see ?? and ??.

3) This documentation also defines implementation-defined behavior; see ??.

#### 4.1.1 Abstract machine

[intro.abstract]

- <sup>1</sup> The semantic descriptions in this document define a parameterized nondeterministic abstract machine. This document places no requirement on the structure of conforming implementations. In particular, they need not copy or emulate the structure of the abstract machine. Rather, conforming implementations are required to emulate (only) the observable behavior of the abstract machine as explained below.<sup>4</sup>
- <sup>2</sup> Certain aspects and operations of the abstract machine are described in this document as implementation-defined (for example, `sizeof(int)`). These constitute the parameters of the abstract machine. Each implementation shall include documentation describing its characteristics and behavior in these respects.<sup>5</sup> Such documentation shall define the instance of the abstract machine that corresponds to that implementation (referred to as the “corresponding instance” below<sup>3</sup>). Certain other aspects and operations of the abstract machine are described in this document as unspecified (for example, evaluation of expressions in a *new-initializer* if the allocation function fails to allocate memory (`??`)). Where possible, this document defines a set of allowable behaviors. These define the nondeterministic aspects of the abstract machine. An instance of the abstract machine can thus have more than one possible execution for a given program and a given input.
- <sup>4</sup> Certain other operations are described in this document as undefined (for example, the effect of attempting to modify a `const` object). [Note: This document imposes no requirements on the behavior of programs that contain undefined behavior. —end note]<sup>6</sup> A conforming implementation executing a well-formed program shall produce the same observable behavior as one of the possible executions of the corresponding instance of the abstract machine with the same program and the same input. However, if any such execution contains an undefined operation, this document places no requirement on the implementation executing that program with that input (not even with regard to operations preceding the first undefined operation).
- <sup>6</sup> The least requirements on a conforming implementation are:
  - (6.1) — Accesses through volatile glvalues are evaluated strictly according to the rules of the abstract machine.
  - (6.2) — At program termination, all data written into files shall be identical to one of the possible results that execution of the program according to the abstract semantics would have produced.
  - (6.3) — The input and output dynamics of interactive devices shall take place in such a fashion that prompting output is actually delivered before a program waits for input. What constitutes an interactive device is implementation-defined.

These collectively are referred to as the *observable behavior* of the program. [Note: More stringent correspondences between abstract and actual semantics may be defined by each implementation. —end note]

- <sup>7</sup> [Note: Operators can be regrouped according to the usual mathematical rules only where the operators really are associative or commutative.<sup>6</sup> For example, in the following fragment

```
int a, b;
/* ... */
a = a + 32760 + b + 5;
```

the expression statement behaves exactly the same as

```
a = (((a + 32760) + b) + 5);
```

---

<sup>4</sup>) This provision is sometimes called the “as-if” rule, because an implementation is free to disregard any requirement of this document as long as the result is *as if* the requirement had been obeyed, as far as can be determined from the observable behavior of the program. For instance, an actual implementation need not evaluate part of an expression if it can deduce that its value is not used and that no side effects affecting the observable behavior of the program are produced.

<sup>5</sup>) This documentation also includes conditionally-supported constructs and locale-specific behavior. See `??`.

<sup>6</sup>) Overloaded operators are never assumed to be associative or commutative.

due to the associativity and precedence of these operators. Thus, the result of the sum (`a + 32760`) is next added to `b`, and that result is then added to 5 which results in the value assigned to `a`. On a machine in which overflows produce an exception and in which the range of values representable by an `int` is `[-32768, +32767]`, the implementation cannot rewrite this expression as

```
a = ((a + b) + 32765);
```

since if the values for `a` and `b` were, respectively, -32754 and -15, the sum `a + b` would produce an exception while the original expression would not; nor can the expression be rewritten either as

```
a = ((a + 32765) + b);
```

or

```
a = (a + (b + 32765));
```

since the values for `a` and `b` might have been, respectively, 4 and -8 or -17 and 12. However on a machine in which overflows do not produce an exception and in which the results of overflows are reversible, the above expression statement can be rewritten by the implementation in any of the above ways because the same result will occur. — *end note*]

## 4.2 Structure of this document

[intro.structure]

- <sup>1</sup> ?? through ?? describe the C++ programming language. That description includes detailed syntactic specifications in a form described in ?. For convenience, ?? repeats all such syntactic specifications.
- <sup>2</sup> ?? through ?? and ?? (the *library clauses*) describe the C++ standard library. That description includes detailed descriptions of the entities and macros that constitute the library, in a form described in ??.
- ?? 到 ?? 和 ??
- ?? recommends lower bounds on the capacity of conforming implementations.
- ?? summarizes the evolution of C++ since its first published description, and explains in detail the differences between C++ and C. Certain features of C++ exist solely for compatibility purposes; ?? describes those features. Throughout this document, each example is introduced by “[ *Example:* ” and terminated by “— *end example* ”]. Each note is introduced by “[ *Note:* ” and terminated by “— *end note* ”]. Examples and notes may be nested.

## 4.3 Syntax notation

[syntax]

- In the syntax notation used in this document, syntactic categories are indicated by *italic* type, and literal words and characters in `constant width` type. Alternatives are listed on separate lines except in a few cases where a long set of alternatives is marked by the phrase “one of”. If the text of an alternative is too long to fit on a line, the text is continued on subsequent lines indented from the first one. An optional terminal or non-terminal symbol is indicated by the subscript “<sub>opt</sub>”, so

```
{ expressionopt }
```

indicates an optional expression enclosed in braces.

- Names for syntactic categories have generally been chosen according to the following rules:
  - (2.1) — *X-name* is a use of an identifier in a context that determines its meaning (e.g., *class-name*, *typedef-name*).
  - (2.2) — *X-id* is an identifier with no context-dependent meaning (e.g., *qualified-id*).
  - (2.3) — *X-seq* is one or more *X*’s without intervening delimiters (e.g., *declaration-seq* is a sequence of declarations).

- (2.4) —  $X\text{-list}$  is one or more  $X$ 's separated by intervening commas (e.g.,  $identifier\text{-list}$  is a sequence of identifiers separated by commas).

#### 4.4 Acknowledgments

[intro.ack]

- <sup>1</sup> The C++ programming language as described in this document is based on the language as described in Chapter R (Reference Manual) of Stroustrup: *The C++ Programming Language* (second edition, Addison-Wesley Publishing Company, ISBN 0-201-53992-6, copyright ©1991 AT&T). That, in turn, is based on the C programming language as described in Appendix A of Kernighan and Ritchie: *The C Programming Language* (Prentice-Hall, 1978, ISBN 0-13-110163-3, copyright ©1978 AT&T).
- <sup>2</sup> Portions of the library Clauses of this document are based on work by P.J. Plauger, which was published as *The Draft Standard C++ Library* (Prentice-Hall, ISBN 0-13-117003-1, copyright ©1995 P.J. Plauger).
- <sup>3</sup> POSIX® is a registered trademark of the Institute of Electrical and Electronic Engineers, Inc.
- <sup>4</sup> ECMAScript® is a registered trademark of Ecma International.
- <sup>5</sup> All rights in these originals are reserved.

## 5 Lexical conventions

[lex]

### 5.1 Separate translation

[lex.separate]

- 1 The text of the program is kept in units called *source files* in this document. A source file together with all the headers (??) and source files included (??) via the preprocessing directive `#include`, less any source lines skipped by any of the conditional inclusion (??) preprocessing directives, is called a *translation unit*. [ *Note*: A C++ program need not all be translated at the same time. — *end note* ]
- 2 [ *Note*: Previously translated translation units and instantiation units can be preserved individually or in libraries. The separate translation units of a program communicate (??) by (for example) calls to functions whose identifiers have external linkage, manipulation of objects whose identifiers have external linkage, or manipulation of data files. Translation units can be separately translated and then later linked to produce an executable program (??). — *end note* ]

### 5.2 Phases of translation

[lex.phases]

- 1 The precedence among the syntax rules of translation is specified by the following phases.<sup>7</sup>

1. Physical source file characters are mapped, in an implementation-defined manner, to the basic source character set (introducing new-line characters for end-of-line indicators) if necessary. The set of physical source file characters accepted is implementation-defined. Any source file character not in the basic source character set (??) is replaced by the *universal-character-name* that designates that character. An implementation may use any internal encoding, so long as an actual extended character encountered in the source file, and the same extended character expressed in the source file as a *universal-character-name* (e.g., using the \uXXXX notation), are handled equivalently except where this replacement is reverted (??) in a raw string literal.
2. Each instance of a backslash character (\) immediately followed by a new-line character is deleted, splicing physical source lines to form logical source lines. Only the last backslash on any physical source line shall be eligible for being part of such a splice. Except for splices reverted in a raw string literal, if a splice results in a character sequence that matches the syntax of a *universal-character-name*, the behavior is undefined. A source file that is not empty and that does not end in a new-line character, or that ends in a new-line character immediately preceded by a backslash character before any such splicing takes place, shall be processed as if an additional new-line character were appended to the file.
3. The source file is decomposed into preprocessing tokens (??) and sequences of white-space characters (including comments). A source file shall not end in a partial preprocessing token or in a partial comment.<sup>8</sup> Each comment is replaced by one space character. New-line characters are retained. Whether each nonempty sequence of white-space characters other than new-line is retained or replaced by one space character is unspecified. The process of dividing a source file's characters into preprocessing tokens is context-dependent. [ *Example*: See the handling of < within a `#include` preprocessing directive. — *end example* ]

<sup>7</sup>) Implementations must behave as if these separate phases occur, although in practice different phases might be folded together.

<sup>8</sup>) A partial preprocessing token would arise from a source file ending in the first portion of a multi-character token that requires a terminating sequence of characters, such as a *header-name* that is missing the closing " or >. A partial comment would arise from a source file ending with an unclosed /\* comment.

4. Preprocessing directives are executed, macro invocations are expanded, and `_Pragma` unary operator expressions are executed. If a character sequence that matches the syntax of a *universal-character-name* is produced by token concatenation (??), the behavior is undefined. A `#include` preprocessing directive causes the named header or source file to be processed from phase 1 through phase 4, recursively. All preprocessing directives are then deleted.
5. Each source character set member in a character literal or a string literal, as well as each escape sequence and *universal-character-name* in a character literal or a non-raw string literal, is converted to the corresponding member of the execution character set (??, ??); if there is no corresponding member, it is converted to an implementation-defined member other than the null (wide) character.<sup>9</sup>
6. Adjacent string literal tokens are concatenated.
7. White-space characters separating tokens are no longer significant. Each preprocessing token is converted into a token (??). The resulting tokens are syntactically and semantically analyzed and translated as a translation unit. [Note: The process of analyzing and translating the tokens may occasionally result in one token being replaced by a sequence of other tokens (??). —end note] [Note: Source files, translation units and translated translation units need not necessarily be stored as files, nor need there be any one-to-one correspondence between these entities and any external representation. The description is conceptual only, and does not specify any particular implementation. —end note]
8. Translated translation units and instantiation units are combined as follows: [Note: Some or all of these may be supplied from a library. —end note] Each translated translation unit is examined to produce a list of required instantiations. [Note: This may include instantiations which have been explicitly requested (??). —end note] The definitions of the required templates are located. It is implementation-defined whether the source of the translation units containing these definitions is required to be available. [Note: An implementation could encode sufficient information into the translated translation unit so as to ensure the source is not required here. —end note] All the required instantiations are performed to produce *instantiation units*. [Note: These are similar to translated translation units, but contain no references to uninstantiated templates and no template definitions. —end note] The program is ill-formed if any instantiation fails.
9. All external entity references are resolved. Library components are linked to satisfy external references to entities not defined in the current translation. All such translator output is collected into a program image which contains information needed for execution in its execution environment.

### 5.3 Character sets

[lex.charset]

- 1 The *basic source character set* consists of 96 characters: the space character, the control characters representing horizontal tab, vertical tab, form feed, and new-line, plus the following 91 graphical characters:<sup>10</sup>

```
a b c d e f g h i j k l m n o p q r s t u v w x y z
A B C D E F G H I J K L M N O P Q R S T U V W X Y Z
0 1 2 3 4 5 6 7 8 9
_ { } [ ] # ( ) < > % : ; . ? * + - / ^ & | ~ ! = , \ " '
```

- 2 The *universal-character-name* construct provides a way to name other characters.

<sup>9</sup>) An implementation need not convert all non-corresponding source characters to the same execution character.

<sup>10</sup>) The glyphs for the members of the basic source character set are intended to identify characters from the subset of ISO/IEC 10646 which corresponds to the ASCII character set. However, because the mapping from source file characters to the source character set (described in translation phase 1) is specified as implementation-defined, an implementation is required to document how the basic source characters are represented in source files.

```

hex-quad:
  hexadecimal-digit hexadecimal-digit hexadecimal-digit hexadecimal-digit

universal-character-name:
  \u hex-quad
  \U hex-quad hex-quad

```

The character designated by the *universal-character-name* \UNNNNNNNNNN is that character whose character short name in ISO/IEC 10646 is NNNNNNNNN; the character designated by the *universal-character-name* \uNNNNNNNN is that character whose character short name in ISO/IEC 10646 is 0000NNNN. If the hexadecimal value for a *universal-character-name* corresponds to a surrogate code point (in the range 0xD800–0xDFFF, inclusive), the program is ill-formed. Additionally, if the hexadecimal value for a *universal-character-name* outside the *c-char-sequence*, *s-char-sequence*, or *r-char-sequence* of a character or string literal corresponds to a control character (in either of the ranges 0x00–0x1F or 0x7F–0x9F, both inclusive) or to a character in the basic source character set, the program is ill-formed.<sup>11</sup>

- 3 The *basic execution character set* and the *basic execution wide-character set* shall each contain all the members of the basic source character set, plus control characters representing alert, backspace, and carriage return, plus a *null character* (respectively, *null wide character*), whose value is 0. For each basic execution character set, the values of the members shall be non-negative and distinct from one another. In both the source and execution basic character sets, the value of each character after 0 in the above list of decimal digits shall be one greater than the value of the previous. The *execution character set* and the *execution wide-character set* are implementation-defined supersets of the basic execution character set and the basic execution wide-character set, respectively. The values of the members of the execution character sets and the sets of additional members are locale-specific.

## 5.4 Preprocessing tokens

[lex.pptoken]

```

preprocessing-token:
  header-name
  identifier
  pp-number
  character-literal
  user-defined-character-literal
  string-literal
  user-defined-string-literal
  preprocessing-op-or-punc
  each non-white-space character that cannot be one of the above

```

- 1 Each preprocessing token that is converted to a token (??) shall have the lexical form of a keyword, an identifier, a literal, an operator, or a punctuator.
- 2 A preprocessing token is the minimal lexical element of the language in translation phases 3 through 6. The categories of preprocessing token are: header names, identifiers, preprocessing numbers, character literals (including user-defined character literals), string literals (including user-defined string literals), preprocessing operators and punctuators, and single non-white-space characters that do not lexically match the other preprocessing token categories. If a ' or a " character matches the last category, the behavior is undefined. Preprocessing tokens can be separated by white space; this consists of comments (??), or white-space characters (space, horizontal tab, new-line, vertical tab, and form-feed), or both. As described in ??, in

---

<sup>11</sup>) A sequence of characters resembling a *universal-character-name* in an *r-char-sequence* (??) does not form a *universal-character-name*.

certain circumstances during translation phase 4, white space (or the absence thereof) serves as more than preprocessing token separation. White space can appear within a preprocessing token only as part of a header name or between the quotation characters in a character literal or string literal.

- <sup>3</sup> If the input stream has been parsed into preprocessing tokens up to a given character:

- (3.1) — If the next character begins a sequence of characters that could be the prefix and initial double quote of a raw string literal, such as R", the next preprocessing token shall be a raw string literal. Between the initial and final double quote characters of the raw string, any transformations performed in phases 1 and 2 (*universal-character-names* and line splicing) are reverted; this reversion shall apply before any *d-char*, *r-char*, or delimiting parenthesis is identified. The raw string literal is defined as the shortest sequence of characters that matches the raw-string pattern

*encoding-prefix<sub>opt</sub>* R *raw-string*

- (3.2) — Otherwise, if the next three characters are <:: and the subsequent character is neither : nor >, the < is treated as a preprocessing token by itself and not as the first character of the alternative token <::.
- (3.3) — Otherwise, the next preprocessing token is the longest sequence of characters that could constitute a preprocessing token, even if that would cause further lexical analysis to fail, except that a *header-name* (??) is only formed within a `#include` directive (??).

[ *Example*:

```
#define R "x"
const char* s = R"y";           // ill-formed raw string, not "x" "y"
— end example ]
```

- <sup>4</sup> [ *Example*: The program fragment 0xe+foo is parsed as a preprocessing number token (one that is not a valid floating or integer literal token), even though a parse as three preprocessing tokens 0xe, +, and foo might produce a valid expression (for example, if foo were a macro defined as 1). Similarly, the program fragment 1E1 is parsed as a preprocessing number (one that is a valid floating literal token), whether or not E is a macro name. — *end example* ]

- <sup>5</sup> [ *Example*: The program fragment x+++++y is parsed as x ++ ++ + y, which, if x and y have integral types, violates a constraint on increment operators, even though the parse x ++ + ++ y might yield a correct expression. — *end example* ]

## 5.5 Alternative tokens

[lex.digraph]

- <sup>1</sup> Alternative token representations are provided for some operators and punctuators.<sup>12</sup>
- <sup>2</sup> In all respects of the language, each alternative token behaves the same, respectively, as its primary token, except for its spelling.<sup>13</sup> The set of alternative tokens is defined in Table ??.

---

<sup>12</sup>) These include “digraphs” and additional reserved words. The term “digraph” (token consisting of two characters) is not perfectly descriptive, since one of the alternative *preprocessing-tokens* is %:%: and of course several primary tokens contain two characters. Nonetheless, those alternative tokens that aren’t lexical keywords are colloquially known as “digraphs”.

<sup>13</sup>) Thus the “stringized” values (??) of [ and <: will be different, maintaining the source spelling, but the tokens can otherwise be freely interchanged.

Table 1 — Alternative tokens

Alternative	Primary	Alternative	Primary	Alternative	Primary
<%	{	and	&&	and_eq	&=
%>	}	bitor		or_eq	=
<:	[	or		xor_eq	^=
:>	]	xor	~	not	!
%:	#	compl	~	not_eq	!=
%::%	##	bitand	&		

## 5.6 Tokens

[lex.token]

*token:*

*identifier*  
*keyword*  
*literal*  
*operator*  
*punctuator*

- <sup>1</sup> There are five kinds of tokens: identifiers, keywords, literals,<sup>14</sup> operators, and other separators. Blanks, horizontal and vertical tabs, newlines, formfeeds, and comments (collectively, “white space”), as described below, are ignored except as they serve to separate tokens. [ *Note*: Some white space is required to separate otherwise adjacent identifiers, keywords, numeric literals, and alternative tokens containing alphabetic characters. — *end note* ]

## 5.7 Comments

[lex.comment]

- <sup>1</sup> The characters /\* start a comment, which terminates with the characters \*/. These comments do not nest. The characters // start a comment, which terminates immediately before the next new-line character. If there is a form-feed or a vertical-tab character in such a comment, only white-space characters shall appear between it and the new-line that terminates the comment; no diagnostic is required. [ *Note*: The comment characters //, /\*, and \*/ have no special meaning within a // comment and are treated just like other characters. Similarly, the comment characters // and /\* have no special meaning within a /\* comment. — *end note* ]

## 5.8 Header names

[lex.header]

*header-name:*

< *h-char-sequence* >  
 " *q-char-sequence* "

*h-char-sequence:*

*h-char*  
*h-char-sequence h-char*

*h-char:*

any member of the source character set except new-line and >

*q-char-sequence:*

*q-char*  
*q-char-sequence q-char*

*q-char:*

any member of the source character set except new-line and "

<sup>14</sup>) Literals include strings and character and numeric literals.

<sup>1</sup> [Note: Header name preprocessing tokens only appear within a `#include` preprocessing directive (see ??). — end note] The sequences in both forms of *header-names* are mapped in an implementation-defined manner to headers or to external source file names as specified in ??.

<sup>2</sup> The appearance of either of the characters ' or \ or of either of the character sequences /\* or // in a *q-char-sequence* or an *h-char-sequence* is conditionally-supported with implementation-defined semantics, as is the appearance of the character " in an *h-char-sequence*.<sup>15</sup>

## 5.9 Preprocessing numbers

[lex.ppnumber]

```
pp-number:
    digit
    . digit
    pp-number digit
    pp-number identifier-nondigit
    pp-number ' digit
    pp-number ' nondigit
    pp-number e sign
    pp-number E sign
    pp-number p sign
    pp-number P sign
    pp-number .
```

- <sup>1</sup> Preprocessing number tokens lexically include all integer literal tokens (??) and all floating literal tokens (??).
- <sup>2</sup> A preprocessing number does not have a type or a value; it acquires both after a successful conversion to an integer literal token or a floating literal token.

## 5.10 Identifiers

[lex.name]

```
identifier:
    identifier-nondigit
    identifier identifier-nondigit
    identifier digit

identifier-nondigit:
    nondigit
    universal-character-name

nondigit: one of
    a b c d e f g h i j k l m
    n o p q r s t u v w x y z
    A B C D E F G H I J K L M
    N O P Q R S T U V W X Y Z _

digit: one of
    0 1 2 3 4 5 6 7 8 9
```

<sup>1</sup> An identifier is an arbitrarily long sequence of letters and digits. Each *universal-character-name* in an identifier shall designate a character whose encoding in ISO 10646 falls into one of the ranges specified in Table ???. The initial element shall not be a *universal-character-name* designating a character whose encoding falls into one of the ranges specified in Table ???. Upper- and lower-case letters are different. All characters are significant.<sup>16</sup>

---

<sup>15</sup>) Thus, a sequence of characters that resembles an escape sequence might result in an error, be interpreted as the character

Table 2 — Ranges of characters allowed

00A8	00AA	00AD	00AF	00B2–00B5
00B7–00BA	00BC–00BE	00C0–00D6	00D8–00F6	00F8–00FF
0100–167F	1681–180D	180F–1FFF		
200B–200D	202A–202E	203F–2040	2054	2060–206F
2070–218F	2460–24FF	2776–2793	2C00–2DFF	2E80–2FFF
3004–3007	3021–302F	3031–D7FF		
F900–FD3D	FD40–FDCF	FDF0–FE44	FE47–FFF	
10000–1FFFFD	20000–2FFFFD	30000–3FFFFD	40000–4FFFFD	50000–5FFFFD
60000–6FFFFD	70000–7FFFFD	80000–8FFFFD	90000–9FFFFD	A0000–AFFFFD
B0000–BFFFFD	C0000–CFFFFD	D0000–DFFFFD	E0000–EFFFFD	

Table 3 — Ranges of characters disallowed initially (combining characters)

0300–036F	1DC0–1DFF	20D0–20FF	FE20–FE2F
-----------	-----------	-----------	-----------

- <sup>2</sup> The identifiers in Table ?? have a special meaning when appearing in a certain context. When referred to in the grammar, these identifiers are used explicitly rather than using the *identifier* grammar production. Unless otherwise specified, any ambiguity as to whether a given *identifier* has a special meaning is resolved to interpret the token as a regular *identifier*.

Table 4 — Identifiers with special meaning

override	final
----------	-------

- <sup>3</sup> In addition, some identifiers are reserved for use by C++ implementations and shall not be used otherwise; no diagnostic is required.
- (3.1) — Each identifier that contains a double underscore `__` or begins with an underscore followed by an uppercase letter is reserved to the implementation for any use.
- (3.2) — Each identifier that begins with an underscore is reserved to the implementation for use as a name in the global namespace.

## 5.11 Keywords

[lex.key]

- <sup>1</sup> The identifiers shown in Table ?? are reserved for use as keywords (that is, they are unconditionally treated as keywords in phase 7) except in an *attribute-token* (??):

[Note: The `export` and `register` keywords are unused but are reserved for future use. — end note]

- <sup>2</sup> Furthermore, the alternative representations shown in Table ?? for certain operators and punctuators (??) are reserved and shall not be used otherwise:

## 5.12 Operators and punctuators

[lex.operators]

- <sup>1</sup> The lexical representation of C++ programs includes a number of preprocessing tokens which are used in the syntax of the preprocessor or are converted into tokens for operators and punctuators:

corresponding to the escape sequence, or have a completely different meaning, depending on the implementation.

16) On systems in which linkers cannot accept extended characters, an encoding of the *universal-character-name* may be used in forming valid external identifiers. For example, some otherwise unused character or sequence of characters may be used to encode the `\u` in a *universal-character-name*. Extended characters may produce a long external identifier, but C++ does not place a translation limit on significant characters for external identifiers. In C++, upper- and lower-case letters are considered different for all identifiers, including external identifiers.

Table 5 — Keywords

alignas	const_cast	for	public	thread_local
alignof	continue	friend	register	throw
asm	decltype	goto	reinterpret_cast	true
auto	default	if	requires	try
bool	delete	inline	return	typedef
break	do	int	short	typeid
case	double	long	signed	typename
catch	dynamic_cast	mutable	sizeof	union
char	else	namespace	static	unsigned
char16_t	enum	new	static_assert	using
char32_t	explicit	noexcept	static_cast	virtual
class	export	nullptr	struct	void
concept	extern	operator	switch	volatile
const	false	private	template	wchar_t
constexpr	float	protected	this	while

Table 6 — Alternative representations

and	and_eq	bitand	bitor	compl	not
not_eq	or	or_eq	xor	xor_eq	

*preprocessing-op-or-punc*: one of

{	}	[	]	#	##	(	)	
<:	:>	<%	%>	%:	%:%:	;	:	...
new	delete	?	::	.	.*	->	->*	~
!	+	-	*	/	%	^	&	
=	==	-=	*=	/=	%=	^=	&=	=
==	!=	<	>	<=	>=	<=>	&&	
<<	>>	<<=	>>=	++	--	,		
and	or	xor	not	bitand	bitor	compl		
and_eq	or_eq	xor_eq	not_eq					

Each *preprocessing-op-or-punc* is converted to a single token in translation phase 7 (??).

## 5.13 Literals

[lex.literal]

### 5.13.1 Kinds of literals

[lex.literal.kinds]

<sup>17</sup> There are several kinds of literals.<sup>17</sup>

*literal*:

- integer-literal*
- character-literal*
- floating-literal*
- string-literal*
- boolean-literal*
- pointer-literal*
- user-defined-literal*

<sup>17)</sup> The term “literal” generally designates, in this document, those tokens that are called “constants” in ISO C.

### 5.13.2 Integer literals

[lex.icon]

*integer-literal:*

- binary-literal integer-suffix<sub>opt</sub>*
- octal-literal integer-suffix<sub>opt</sub>*
- decimal-literal integer-suffix<sub>opt</sub>*
- hexadecimal-literal integer-suffix<sub>opt</sub>*

*binary-literal:*

- 0b binary-digit*
- 0B binary-digit*
- binary-literal ' opt binary-digit*

*octal-literal:*

- 0*
- octal-literal ' opt octal-digit*

*decimal-literal:*

- nonzero-digit*
- decimal-literal ' opt digit*

*hexadecimal-literal:*

- hexadecimal-prefix hexadecimal-digit-sequence*

*binary-digit:*

- 0*
- 1*

*octal-digit:* one of

- 0 1 2 3 4 5 6 7*

*nonzero-digit:* one of

- 1 2 3 4 5 6 7 8 9*

*hexadecimal-prefix:* one of

- 0x 0X*

*hexadecimal-digit-sequence:*

- hexadecimal-digit*
- hexadecimal-digit-sequence ' opt hexadecimal-digit*

*hexadecimal-digit:* one of

- 0 1 2 3 4 5 6 7 8 9*
- a b c d e f*
- A B C D E F*

*integer-suffix:*

- unsigned-suffix long-suffix<sub>opt</sub>*
- unsigned-suffix long-long-suffix<sub>opt</sub>*
- long-suffix unsigned-suffix<sub>opt</sub>*
- long-long-suffix unsigned-suffix<sub>opt</sub>*

*unsigned-suffix:* one of

- u U*

*long-suffix:* one of

- l L*

*long-long-suffix:* one of

- ll LL*

- <sup>1</sup> An *integer literal* is a sequence of digits that has no period or exponent part, with optional separating single quotes that are ignored when determining its value. An integer literal may have a prefix that specifies its base and a suffix that specifies its type. The lexically first digit of the sequence of digits is the most significant. A *binary integer literal* (base two) begins with 0b or 0B and consists of a sequence of binary digits. An *octal integer literal* (base eight) begins with the digit 0 and consists of a sequence of octal digits.<sup>18</sup> A *decimal integer literal* (base ten) begins with a digit other than 0 and consists of a sequence of decimal digits. A *hexadecimal integer literal* (base sixteen) begins with 0x or 0X and consists of a sequence of hexadecimal digits, which include the decimal digits and the letters a through f and A through F with decimal values ten through fifteen. [ *Example:* The number twelve can be written 12, 014, 0XC, or 0b1100. The integer literals 1048576, 1'048'576, 0X100000, 0x10'0000, and 0'004'000'000 all have the same value. — *end example* ]
- <sup>2</sup> The type of an integer literal is the first of the corresponding list in Table ?? in which its value can be represented.

Table 7 — Types of integer literals

Suffix	Decimal literal	Binary, octal, or hexadecimal literal
none	int long int long long int	int unsigned int long int unsigned long int long long int unsigned long long int
u or U	unsigned int unsigned long int unsigned long long int	unsigned int unsigned long int unsigned long long int
l or L	long int long long int	long int unsigned long int long long int unsigned long long int
Both u or U and l or L	unsigned long int unsigned long long int	unsigned long int unsigned long long int
ll or LL	long long int	long long int unsigned long long int
Both u or U and ll or LL	unsigned long long int	unsigned long long int

- <sup>3</sup> If an integer literal cannot be represented by any type in its list and an extended integer type (??) can represent its value, it may have that extended integer type. If all of the types in the list for the integer literal are signed, the extended integer type shall be signed. If all of the types in the list for the integer literal are unsigned, the extended integer type shall be unsigned. If the list contains both signed and unsigned types, the extended integer type may be signed or unsigned. A program is ill-formed if one of its translation units contains an integer literal that cannot be represented by any of the allowed types.

18) The digits 8 and 9 are not octal digits.

### 5.13.3 Character literals

[lex.ccon]

*character-literal:*

*encoding-prefix<sub>opt</sub>* , *c-char-sequence* ,

*encoding-prefix*: one of

u8 u U L

*c-char-sequence*:

*c-char*

*c-char-sequence c-char*

*c-char*:

any member of the source character set except

the single-quote ' , backslash \, or new-line character

*escape-sequence*

*universal-character-name*

*escape-sequence*:

*simple-escape-sequence*

*octal-escape-sequence*

*hexadecimal-escape-sequence*

*simple-escape-sequence*: one of

\' " ? \\  
\\a \\b \\f \\n \\r \\t \\v

*octal-escape-sequence*:

\ octal-digit  
\\ octal-digit octal-digit  
\\\\ octal-digit octal-digit octal-digit

*hexadecimal-escape-sequence*:

\\x hexadecimal-digit  
hexadecimal-escape-sequence hexadecimal-digit

- <sup>1</sup> A character literal is one or more characters enclosed in single quotes, as in 'x', optionally preceded by u8, u, U, or L, as in u8'w', u'x', U'y', or L'z', respectively.
- <sup>2</sup> A character literal that does not begin with u8, u, U, or L is an *ordinary character literal*. An ordinary character literal that contains a single *c-char* representable in the execution character set has type **char**, with value equal to the numerical value of the encoding of the *c-char* in the execution character set. An ordinary character literal that contains more than one *c-char* is a *multicharacter literal*. A multicharacter literal, or an ordinary character literal containing a single *c-char* not representable in the execution character set, is conditionally-supported, has type **int**, and has an implementation-defined value.
- <sup>3</sup> A character literal that begins with u8, such as u8'w', is a character literal of type **char**, known as a *UTF-8 character literal*. The value of a UTF-8 character literal is equal to its ISO 10646 code point value, provided that the code point value is representable with a single UTF-8 code unit (that is, provided it is in the C0 Controls and Basic Latin Unicode block). If the value is not representable with a single UTF-8 code unit, the program is ill-formed. A UTF-8 character literal containing multiple *c-chars* is ill-formed.
- <sup>4</sup> A character literal that begins with the letter u, such as u'x', is a character literal of type **char16\_t**. The value of a **char16\_t** character literal containing a single *c-char* is equal to its ISO 10646 code point value, provided that the code point value is representable with a single 16-bit code unit (that is, provided it is in

the basic multi-lingual plane). If the value is not representable with a single 16-bit code unit, the program is ill-formed. A `char16_t` character literal containing multiple *c-chars* is ill-formed.

- 5 A character literal that begins with the letter U, such as U'y', is a character literal of type `char32_t`. The value of a `char32_t` character literal containing a single *c-char* is equal to its ISO 10646 code point value. A `char32_t` character literal containing multiple *c-chars* is ill-formed.
- 6 A character literal that begins with the letter L, such as L'z', is a *wide-character literal*. A wide-character literal has type `wchar_t`.<sup>19</sup> The value of a wide-character literal containing a single *c-char* has value equal to the numerical value of the encoding of the *c-char* in the execution wide-character set, unless the *c-char* has no representation in the execution wide-character set, in which case the value is implementation-defined. [ *Note*: The type `wchar_t` is able to represent all members of the execution wide-character set (see ??). — *end note* ] The value of a wide-character literal containing multiple *c-chars* is implementation-defined.
- 7 Certain non-graphic characters, the single quote ', the double quote ", the question mark ?,<sup>20</sup> and the backslash \, can be represented according to Table ?? . The double quote " and the question mark ?, can be represented as themselves or by the escape sequences \" and \\? respectively, but the single quote ' and the backslash \ shall be represented by the escape sequences \' and \\\" respectively. Escape sequences in which the character following the backslash is not listed in Table ?? are conditionally-supported, with implementation-defined semantics. An escape sequence specifies a single character.

Table 8 — Escape sequences

new-line	NL(LF)	\n
horizontal tab	HT	\t
vertical tab	VT	\v
backspace	BS	\b
carriage return	CR	\r
form feed	FF	\f
alert	BEL	\a
backslash	\	\\
question mark	?	\?
single quote	'	\'
double quote	"	\"
octal number	ooo	\ooo
hex number	hhh	\xhhh

- 8 The escape \ooo consists of the backslash followed by one, two, or three octal digits that are taken to specify the value of the desired character. The escape \xhhh consists of the backslash followed by x followed by one or more hexadecimal digits that are taken to specify the value of the desired character. There is no limit to the number of digits in a hexadecimal sequence. A sequence of octal or hexadecimal digits is terminated by the first character that is not an octal digit or a hexadecimal digit, respectively. The value of a character literal is implementation-defined if it falls outside of the implementation-defined range defined for `char` (for character literals with no prefix) or `wchar_t` (for character literals prefixed by L). [ *Note*: If the value of a character literal prefixed by u, u8, or U is outside the range defined for its type, the program is ill-formed. — *end note* ]
- 9 A *universal-character-name* is translated to the encoding, in the appropriate execution character set, of the character named. If there is no such encoding, the *universal-character-name* is translated to an implementation-defined encoding. [ *Note*: In translation phase 1, a *universal-character-name* is introduced whenever an actual

19) They are intended for character sets where a character does not fit into a single byte.

20) Using an escape sequence for a question mark is supported for compatibility with ISO C++ 2014 and ISO C.

extended character is encountered in the source text. Therefore, all extended characters are described in terms of *universal-character-names*. However, the actual compiler implementation may use its own native character set, so long as the same results are obtained. — *end note*]

### 5.13.4 Floating literals

[lex.fcon]

*floating-literal*:

*decimal-floating-literal*

*hexadecimal-floating-literal*

*decimal-floating-literal*:

*fractional-constant exponent-part<sub>opt</sub> floating-suffix<sub>opt</sub>*

*digit-sequence exponent-part floating-suffix<sub>opt</sub>*

*hexadecimal-floating-literal*:

*hexadecimal-prefix hexadecimal-fractional-constant binary-exponent-part floating-suffix<sub>opt</sub>*

*hexadecimal-prefix hexadecimal-digit-sequence binary-exponent-part floating-suffix<sub>opt</sub>*

*fractional-constant*:

*digit-sequence<sub>opt</sub> . digit-sequence*

*digit-sequence .*

*hexadecimal-fractional-constant*:

*hexadecimal-digit-sequence<sub>opt</sub> . hexadecimal-digit-sequence*

*hexadecimal-digit-sequence .*

*exponent-part*:

*e sign<sub>opt</sub> digit-sequence*

*E sign<sub>opt</sub> digit-sequence*

*binary-exponent-part*:

*p sign<sub>opt</sub> digit-sequence*

*P sign<sub>opt</sub> digit-sequence*

*sign*: one of

+ -

*digit-sequence*:

*digit*

*digit-sequence ' opt digit*

*floating-suffix*: one of

*f l F L*

<sup>1</sup> A floating literal consists of an optional prefix specifying a base, an integer part, a radix point, a fraction part, an e, E, p or P, an optionally signed integer exponent, and an optional type suffix. The integer and fraction parts both consist of a sequence of decimal (base ten) digits if there is no prefix, or hexadecimal (base sixteen) digits if the prefix is 0x or 0X. The floating literal is a *decimal floating literal* in the former case and a *hexadecimal floating literal* in the latter case. Optional separating single quotes in a *digit-sequence* or *hexadecimal-digit-sequence* are ignored when determining its value. [Example: The floating literals 1.602'176'565e-19 and 1.602176565e-19 have the same value. — end example] Either the integer part or the fraction part (not both) can be omitted. Either the radix point or the letter e or E and the exponent (not both) can be omitted from a decimal floating literal. The radix point (but not the exponent) can be omitted from a hexadecimal floating literal. The integer part, the optional radix point, and the optional fraction part, form the *significand* of the floating literal. In a decimal floating literal, the exponent, if present, indicates the power of 10 by which the significand is to be scaled. In a hexadecimal floating literal, the exponent

indicates the power of 2 by which the significand is to be scaled. [*Example*: The floating literals 49.625 and 0xC.68p+2 have the same value. — *end example*] If the scaled value is in the range of representable values for its type, the result is the scaled value if representable, else the larger or smaller representable value nearest the scaled value, chosen in an implementation-defined manner. The type of a floating literal is `double` unless explicitly specified by a suffix. The suffixes `f` and `F` specify `float`, the suffixes `l` and `L` specify `long double`. If the scaled value is not in the range of representable values for its type, the program is ill-formed.

### 5.13.5 String literals

[lex.string]

*string-literal*:

- encoding-prefix<sub>opt</sub>* " *s-char-sequence<sub>opt</sub>* "
- encoding-prefix<sub>opt</sub>* R *raw-string*

*s-char-sequence*:

- s-char*
- s-char-sequence s-char*

*s-char*:

- any member of the source character set except
- the double-quote ", backslash \, or new-line character
- escape-sequence*
- universal-character-name*

*raw-string*:

- " *d-char-sequence<sub>opt</sub>* ( *r-char-sequence<sub>opt</sub>* ) *d-char-sequence<sub>opt</sub>* "

*r-char-sequence*:

- r-char*
- r-char-sequence r-char*

*r-char*:

- any member of the source character set, except
- a right parenthesis ) followed by the initial *d-char-sequence*
- (which may be empty) followed by a double quote ".

*d-char-sequence*:

- d-char*
- d-char-sequence d-char*

*d-char*:

- any member of the basic source character set except:
- space, the left parenthesis (, the right parenthesis ), the backslash \,
- and the control characters representing horizontal tab,
- vertical tab, form feed, and newline.

- 1 A *string-literal* is a sequence of characters (as defined in ??) surrounded by double quotes, optionally prefixed by R, u8, u8R, u, uR, U, UR, L, or LR, as in "...", R"(...)", u8"...", u8R"\*\*(...)\*\*", u"...", uR"\*~(...)\*~", U"...", UR"zzz(...)zzz", L"...", or LR"(...)", respectively.
- 2 A *string-literal* that has an R in the prefix is a *raw string literal*. The *d-char-sequence* serves as a delimiter. The terminating *d-char-sequence* of a *raw-string* is the same sequence of characters as the initial *d-char-sequence*. A *d-char-sequence* shall consist of at most 16 characters.
- 3 [Note: The characters '(' and ')' are permitted in a *raw-string*. Thus, R"delimiter((a|b))delimiter" is equivalent to "(a|b)". — *end note*]

- <sup>4</sup> [Note: A source-file new-line in a raw string literal results in a new-line in the resulting execution string literal. Assuming no whitespace at the beginning of lines in the following example, the assert will succeed:

```
const char* p = R"(a\
b
c)";
assert(std::strcmp(p, "a\\nb\\nc") == 0);
— end note]
```

- <sup>5</sup> [Example: The raw string

```
R"a(
)\\
a"
)a"
```

is equivalent to "\n)\\na\". The raw string

```
R"(x = "\"y\"")"
```

is equivalent to "x = \"\\\"y\\\"\"". — end example]

- <sup>6</sup> After translation phase 6, a *string-literal* that does not begin with an *encoding-prefix* is an *ordinary string literal*, and is initialized with the given characters.
- <sup>7</sup> A *string-literal* that begins with u8, such as u8"asdf", is a *UTF-8 string literal*.
- <sup>8</sup> Ordinary string literals and UTF-8 string literals are also referred to as narrow string literals. A narrow string literal has type “array of *n const char*”, where *n* is the size of the string as defined below, and has static storage duration (??).
- <sup>9</sup> For a UTF-8 string literal, each successive element of the object representation (??) has the value of the corresponding code unit of the UTF-8 encoding of the string.
- <sup>10</sup> A *string-literal* that begins with u, such as u"asdf", is a *char16\_t* string literal. A *char16\_t* string literal has type “array of *n const char16\_t*”, where *n* is the size of the string as defined below; it is initialized with the given characters. A single *c-char* may produce more than one *char16\_t* character in the form of surrogate pairs.
- <sup>11</sup> A *string-literal* that begins with U, such as U"asdf", is a *char32\_t* string literal. A *char32\_t* string literal has type “array of *n const char32\_t*”, where *n* is the size of the string as defined below; it is initialized with the given characters.
- <sup>12</sup> A *string-literal* that begins with L, such as L"asdf", is a *wide string literal*. A wide string literal has type “array of *n const wchar\_t*”, where *n* is the size of the string as defined below; it is initialized with the given characters.
- <sup>13</sup> In translation phase 6 (??), adjacent *string-literals* are concatenated. If both *string-literals* have the same *encoding-prefix*, the resulting concatenated string literal has that *encoding-prefix*. If one *string-literal* has no *encoding-prefix*, it is treated as a *string-literal* of the same *encoding-prefix* as the other operand. If a UTF-8 string literal token is adjacent to a wide string literal token, the program is ill-formed. Any other concatenations are conditionally-supported with implementation-defined behavior. [Note: This concatenation is an interpretation, not a conversion. Because the interpretation happens in translation phase 6 (after each character from a string literal has been translated into a value from the appropriate character set), a *string-literal*'s initial rawness has no effect on the interpretation or well-formedness of the concatenation. — end note] Table ?? has some examples of valid concatenations.

Table 9 — String literal concatenations

Source	Means	Source	Means	Source	Means
u" a "	u" b "	u" ab "	U" a "	U" b "	U" ab "
u" a "	" b "	u" ab "	U" a "	" b "	U" ab "
" a "	u" b "	u" ab "	" a "	U" b "	U" ab "

Characters in concatenated strings are kept distinct.

[*Example:*

"\xA" "B"

contains the two characters '\xA' and 'B' after concatenation (and not the single hexadecimal character '\xAB'). — *end example*]

- <sup>14</sup> After any necessary concatenation, in translation phase 7 (??), '\0' is appended to every string literal so that programs that scan a string can find its end.
- <sup>15</sup> Escape sequences and *universal-character-names* in non-raw string literals have the same meaning as in character literals (??), except that the single quote ' is representable either by itself or by the escape sequence '\, and the double quote " shall be preceded by a \, and except that a *universal-character-name* in a `char16_t` string literal may yield a surrogate pair. In a narrow string literal, a *universal-character-name* may map to more than one `char` element due to *multibyte encoding*. The size of a `char32_t` or wide string literal is the total number of escape sequences, *universal-character-names*, and other characters, plus one for the terminating U'\0' or L'\0'. The size of a `char16_t` string literal is the total number of escape sequences, *universal-character-names*, and other characters, plus one for each character requiring a surrogate pair, plus one for the terminating u'\0'. [Note: The size of a `char16_t` string literal is the number of code units, not the number of characters. — *end note*] Within `char32_t` and `char16_t` string literals, any *universal-character-names* shall be within the range 0x0 to 0x10FFFF. The size of a narrow string literal is the total number of escape sequences and other characters, plus at least one for the multibyte encoding of each *universal-character-name*, plus one for the terminating '\0'.
- <sup>16</sup> Evaluating a *string-literal* results in a string literal object with static storage duration, initialized from the given characters as specified above. Whether all string literals are distinct (that is, are stored in nonoverlapping objects) and whether successive evaluations of a *string-literal* yield the same or a different object is unspecified. [Note: The effect of attempting to modify a string literal is undefined. — *end note*]

### 5.13.6 Boolean literals

[lex.bool]

*boolean-literal:*

```
    false
    true
```

- <sup>1</sup> The Boolean literals are the keywords `false` and `true`. Such literals are prvalues and have type `bool`.

### 5.13.7 Pointer literals

[lex.nullptr]

*pointer-literal:*

```
    nullptr
```

- <sup>1</sup> The pointer literal is the keyword `nullptr`. It is a prvalue of type `std::nullptr_t`. [Note: `std::nullptr_t` is a distinct type that is neither a pointer type nor a pointer-to-member type; rather, a prvalue of this type is a null pointer constant and can be converted to a null pointer value or null member pointer value. See ?? and ???. — *end note*]

### 5.13.8 User-defined literals

[lex.ext]

```

user-defined-literal:
  user-defined-integer-literal
  user-defined-floating-literal
  user-defined-string-literal
  user-defined-character-literal

user-defined-integer-literal:
  decimal-literal ud-suffix
  octal-literal ud-suffix
  hexadecimal-literal ud-suffix
  binary-literal ud-suffix

user-defined-floating-literal:
  fractional-constant exponent-partopt ud-suffix
  digit-sequence exponent-part ud-suffix
  hexadecimal-prefix hexadecimal-fractional-constant binary-exponent-part ud-suffix
  hexadecimal-prefix hexadecimal-digit-sequence binary-exponent-part ud-suffix

user-defined-string-literal:
  string-literal ud-suffix

user-defined-character-literal:
  character-literal ud-suffix

ud-suffix:
  identifier

```

- <sup>1</sup> If a token matches both *user-defined-literal* and another *literal* kind, it is treated as the latter. [ *Example*: `123_km` is a *user-defined-literal*, but `12LL` is an *integer-literal*. — *end example* ] The syntactic non-terminal preceding the *ud-suffix* in a *user-defined-literal* is taken to be the longest sequence of characters that could match that non-terminal.
- <sup>2</sup> A *user-defined-literal* is treated as a call to a literal operator or literal operator template (??). To determine the form of this call for a given *user-defined-literal* *L* with *ud-suffix* *X*, the *literal-operator-id* whose literal suffix identifier is *X* is looked up in the context of *L* using the rules for unqualified name lookup (??). Let *S* be the set of declarations found by this lookup. *S* shall not be empty.
- <sup>3</sup> If *L* is a *user-defined-integer-literal*, let *n* be the literal without its *ud-suffix*. If *S* contains a literal operator with parameter type `unsigned long long`, the literal *L* is treated as a call of the form

`operator "" X(nULL)`

Otherwise, *S* shall contain a raw literal operator or a literal operator template (??) but not both. If *S* contains a raw literal operator, the literal *L* is treated as a call of the form

`operator "" X("n")`

Otherwise (*S* contains a literal operator template), *L* is treated as a call of the form

`operator "" X<'c1', 'c2', ... 'ck'>()`

where *n* is the source character sequence *c<sub>1</sub>c<sub>2</sub>...c<sub>k</sub>*. [ *Note*: The sequence *c<sub>1</sub>c<sub>2</sub>...c<sub>k</sub>* can only contain characters from the basic source character set. — *end note* ]

- <sup>4</sup> If *L* is a *user-defined-floating-literal*, let *f* be the literal without its *ud-suffix*. If *S* contains a literal operator with parameter type `long double`, the literal *L* is treated as a call of the form

`operator "" X(fL)`

Otherwise,  $S$  shall contain a raw literal operator or a literal operator template (??) but not both. If  $S$  contains a raw literal operator, the *literal L* is treated as a call of the form

```
operator "" X("f")
```

Otherwise ( $S$  contains a literal operator template),  $L$  is treated as a call of the form

```
operator "" X<'c1', 'c2', ... 'ck'>()
```

where  $f$  is the source character sequence  $c_1 c_2 \dots c_k$ . [Note: The sequence  $c_1 c_2 \dots c_k$  can only contain characters from the basic source character set. —end note]

- <sup>5</sup> If  $L$  is a *user-defined-string-literal*, let  $str$  be the literal without its *ud-suffix* and let  $len$  be the number of code units in  $str$  (i.e., its length excluding the terminating null character). The literal  $L$  is treated as a call of the form

```
operator "" X(str, len)
```

- <sup>6</sup> If  $L$  is a *user-defined-character-literal*, let  $ch$  be the literal without its *ud-suffix*.  $S$  shall contain a literal operator (??) whose only parameter has the type of  $ch$  and the literal  $L$  is treated as a call of the form

```
operator "" X(ch)
```

- <sup>7</sup> [Example:

```
long double operator "" _w(long double);
std::string operator "" _w(const char16_t*, std::size_t);
unsigned operator "" _w(const char*);
int main() {
    1.2_w;           // calls operator "" _w(1.2L)
    u"one"_w;       // calls operator "" _w(u"one", 3)
    12_w;           // calls operator "" _w("12")
    "two"_w;         // error: no applicable literal operator
}
```

—end example]

- <sup>8</sup> In translation phase 6 (??), adjacent string literals are concatenated and *user-defined-string-literals* are considered string literals for that purpose. During concatenation, *ud-suffixes* are removed and ignored and the concatenation process occurs as described in ???. At the end of phase 6, if a string literal is the result of a concatenation involving at least one *user-defined-string-literal*, all the participating *user-defined-string-literals* shall have the same *ud-suffix* and that suffix is applied to the result of the concatenation.

- <sup>9</sup> [Example:

```
int main() {
    L"A" "B" "C"_x; // OK: same as L"ABC"_x
    "P"_x "Q" "R"_y; // error: two different ud-suffixes
}
```

—end example]

## 6 Basic concepts [basic]

- <sup>1</sup> [*Note*: This Clause presents the basic concepts of the C++ language. It explains the difference between an object and a name and how they relate to the value categories for expressions. It introduces the concepts of a declaration and a definition and presents C++'s notion of type, scope, linkage, and storage duration. The mechanisms for starting and terminating a program are discussed. Finally, this Clause presents the fundamental types of the language and lists the ways of constructing compound types from these. — *end note*]
- <sup>2</sup> [*Note*: This Clause does not cover concepts that affect only a single part of the language. Such concepts are discussed in the relevant Clauses. — *end note*]
- <sup>3</sup> An *entity* is a value, object, reference, structured binding, function, enumerator, type, class member, bit-field, template, template specialization, namespace, or parameter pack.
- <sup>4</sup> A *name* is a use of an *identifier* (??), *operator-function-id* (??), *literal-operator-id* (??), *conversion-function-id* (??), or *template-id* (??) that denotes an entity or label (??, ??).
- <sup>5</sup> Every name that denotes an entity is introduced by a *declaration*. Every name that denotes a label is introduced either by a `goto` statement (??) or a *labeled-statement* (??).
- <sup>6</sup> A *variable* is introduced by the declaration of a reference other than a non-static data member or of an object. The variable's name, if any, denotes the reference or object.
- <sup>7</sup> A *local entity* is a variable with automatic storage duration (??), a structured binding (??) whose corresponding variable is such an entity, or the `*this` object (??).
- <sup>8</sup> Some names denote types or templates. In general, whenever a name is encountered it is necessary to determine whether that name denotes one of these entities before continuing to parse the program that contains it. The process that determines this is called *name lookup* (??).
- <sup>9</sup> Two names are *the same* if
  - (9.1) — they are *identifiers* composed of the same character sequence, or
  - (9.2) — they are *operator-function-ids* formed with the same operator, or
  - (9.3) — they are *conversion-function-ids* formed with the same type, or
  - (9.4) — they are *template-ids* that refer to the same class, function, or variable (??), or
  - (9.5) — they are the names of literal operators (??) formed with the same literal suffix identifier.
- <sup>10</sup> A name used in more than one translation unit can potentially refer to the same entity in these translation units depending on the linkage (??) of the name specified in each translation unit.

### 6.1 Declarations and definitions

[basic.def]

- <sup>1</sup> A declaration (??) may introduce one or more names into a translation unit or redeclare names introduced by previous declarations. If so, the declaration specifies the interpretation and attributes of these names. A declaration may also have effects including:
  - (1.1) — a static assertion (??),
  - (1.2) — controlling template instantiation (??),

- (1.3) — guiding template argument deduction for constructors (??),
- (1.4) — use of attributes (??), and
- (1.5) — nothing (in the case of an *empty-declaration*).

2 A declaration is a *definition* unless

- (2.1) — it declares a function without specifying the function's body (??),
- (2.2) — it contains the `extern` specifier (??) or a *linkage-specification*<sup>21</sup> (??) and neither an *initializer* nor a *function-body*,
- (2.3) — it declares a non-inline static data member in a class definition (??, ??),
- (2.4) — it declares a static data member outside a class definition and the variable was defined within the class with the `constexpr` specifier (this usage is deprecated; see ??),
- (2.5) — it is a class name declaration (??),
- (2.6) — it is an *opaque-enum-declaration* (??),
- (2.7) — it is a *template-parameter* (??),
- (2.8) — it is a *parameter-declaration* (??) in a function declarator that is not the *declarator* of a *function-definition*,
- (2.9) — it is a `typedef` declaration (??),
- (2.10) — it is an *alias-declaration* (??),
- (2.11) — it is a *using-declaration* (??),
- (2.12) — it is a *deduction-guide* (??),
- (2.13) — it is a *static\_assert-declaration* (??),
- (2.14) — it is an *attribute-declaration* (??),
- (2.15) — it is an *empty-declaration* (??),
- (2.16) — it is a *using-directive* (??),
- (2.17) — it is an explicit instantiation declaration (??), or
- (2.18) — it is an explicit specialization (??) whose *declaration* is not a definition.

[*Example*: All but one of the following are definitions:

```

int a;                                // defines a
extern const int c = 1;                 // defines c
int f(int x) { return x+a; }           // defines f and defines x
struct S { int a; int b; };             // defines S, S::a, and S::b
struct X {
    int x;                            // defines non-static data member x
    static int y;                     // declares static data member y
    X(): x(0) {}                   // defines a constructor of X
};
int X::y = 1;                          // defines X::y
enum { up, down };                    // defines up and down
namespace N { int d; }                // defines N and N::d

```

<sup>21</sup>) Appearing inside the brace-enclosed *declaration-seq* in a *linkage-specification* does not affect whether a declaration is a definition.

```
namespace N1 = N;           // defines N1
X anX;                   // defines anX
```

whereas these are just declarations:

```
extern int a;               // declares a
extern const int c;         // declares c
int f(int);                // declares f
struct S;                  // declares S
typedef int Int;            // declares Int
extern X anotherX;          // declares anotherX
using N::d;                 // declares d

— end example]
```

- <sup>3</sup> [Note: In some circumstances, C++ implementations implicitly define the default constructor (??), copy constructor (??), move constructor (??), copy assignment operator (??), move assignment operator (??), or destructor (??) member functions. — end note] [Example: Given

```
#include <string>

struct C {
    std::string s;           // std::string is the standard library class (??)
};

int main() {
    C a;
    C b = a;
    b = a;
}
```

the implementation will implicitly define functions to make the definition of C equivalent to

```
struct C {
    std::string s;
C(): s() { }
C(const C& x): s(x.s) { }
C(C& x): s(static_cast<std::string&&>(x.s)) { }
    // : s(std::move(x.s)) { }
C& operator=(const C& x) { s = x.s; return *this; }
C& operator=(C& x) { s = static_cast<std::string&&>(x.s); return *this; }
    // { s = std::move(x.s); return *this; }
~C() { }

};

— end example]
```

- <sup>4</sup> [Note: A class name can also be implicitly declared by an *elaborated-type-specifier* (??). — end note]

- <sup>5</sup> A program is ill-formed if the definition of any object gives the object an incomplete type (??).

## 6.2 One-definition rule

[**basic.def.odr**]

- <sup>1</sup> No translation unit shall contain more than one definition of any variable, function, class type, enumeration type, or template.

- <sup>2</sup> An expression is *potentially evaluated* unless it is an unevaluated operand (??) or a subexpression thereof. The set of *potential results* of an expression **e** is defined as follows:

- (2.1) — If **e** is an *id-expression* (??), the set contains only **e**.
- (2.2) — If **e** is a subscripting operation (??) with an array operand, the set contains the potential results of that operand.
- (2.3) — If **e** is a class member access expression (??), the set contains the potential results of the object expression.
- (2.4) — If **e** is a pointer-to-member expression (??) whose second operand is a constant expression, the set contains the potential results of the object expression.
- (2.5) — If **e** has the form (**e**1), the set contains the potential results of **e**1.
- (2.6) — If **e** is a glvalue conditional expression (??), the set is the union of the sets of potential results of the second and third operands.
- (2.7) — If **e** is a comma expression (??), the set contains the potential results of the right operand.
- (2.8) — Otherwise, the set is empty.

[*Note*: This set is a (possibly-empty) set of *id-expressions*, each of which is either **e** or a subexpression of **e**.

[*Example*: In the following example, the set of potential results of the initializer of **n** contains the first **S::x** subexpression, but not the second **S::x** subexpression.

```
struct S { static const int x = 0; };
const int &f(const int &r);
int n = b ? (1, S::x)           // S::x is not odr-used here
          : f(S::x);           // S::x is odr-used here, so a definition is required
```

— end example] — end note]

- <sup>3</sup> A function is *named by an expression* as follows:

- (3.1) — A function whose name appears in an expression is named by that expression if it is the unique lookup result or the selected member of a set of overloaded functions (??, ??, ??), unless it is a pure virtual function and either its name is not explicitly qualified or the expression forms a pointer to member (??). [*Note*: This covers taking the address of functions (??, ??), calls to named functions (??), operator overloading (??), user-defined conversions (??), allocation functions for placement *new-expressions* (??), as well as non-default initialization (??). A constructor selected to copy or move an object of class type is considered to be named by an expression even if the call is actually elided by the implementation (??). — end note]
- (3.2) — An allocation or deallocation function for a class is named by a *new-expression* as specified in ?? and ??.
- (3.3) — A deallocation function for a class is named by a delete expression as specified in ?? and ??.

<sup>4</sup> A variable **x** whose name appears as a potentially-evaluated expression **ex** is *odr-used* by **ex** unless applying the lvalue-to-rvalue conversion (??) to **x** yields a constant expression (??) that does not invoke any non-trivial functions and, if **x** is an object, **ex** is an element of the set of potential results of an expression **e**, where either the lvalue-to-rvalue conversion (??) is applied to **e**, or **e** is a discarded-value expression (??).

<sup>5</sup> A structured binding is odr-used if it appears as a potentially-evaluated expression.

<sup>6</sup> **\*this** is odr-used if **this** appears as a potentially-evaluated expression (including as the result of the implicit transformation in the body of a non-static member function (??)).

- <sup>7</sup> A virtual member function is odr-used if it is not pure. A function is odr-used if it is named by a potentially-evaluated expression. A non-placement allocation or deallocation function for a class is odr-used by the definition of a constructor of that class. A non-placement deallocation function for a class is odr-used by the definition of the destructor of that class, or by being selected by the lookup at the point of definition of a virtual destructor (??).<sup>22</sup>
- <sup>8</sup> An assignment operator function in a class is odr-used by an implicitly-defined copy-assignment or move-assignment function for another class as specified in ???. A constructor for a class is odr-used as specified in ???. A destructor for a class is odr-used if it is potentially invoked (??).
- <sup>9</sup> A local entity (??) is *odr-usable* in a declarative region (??) if:
- (9.1) — the local entity is either not `*this`, or an enclosing class or non-lambda function parameter scope exists and, if the innermost such scope is a function parameter scope, it corresponds to a non-static member function, and
  - (9.2) — for each intervening declarative region (??) between the point at which the entity is introduced and the region (where `*this` is considered to be introduced within the innermost enclosing class or non-lambda function definition scope), either:
    - (9.2.1) — the declarative region is a block scope, or
    - (9.2.2) — the declarative region is the function parameter scope of a *lambda-expression* that has a *simple-capture* naming the entity or has a *capture-default*.

If a local entity is odr-used in a declarative region in which it is not odr-usable, the program is ill-formed.

[*Example*:

```
void f(int n) {
    [] { n = 1; };                                // error, n is not odr-usable due to intervening lambda-expression
    struct A {
        void f() { n = 2; }                      // error, n is not odr-usable due to intervening function definition scope
    };
    void g(int = n);                            // error, n is not odr-usable due to intervening function parameter scope
    [&] { [n]{ return n; }; };                  // OK
}
```

— *end example*]

- <sup>10</sup> Every program shall contain exactly one definition of every non-inline function or variable that is odr-used in that program outside of a discarded statement (??); no diagnostic required. The definition can appear explicitly in the program, it can be found in the standard or a user-defined library, or (when appropriate) it is implicitly defined (see ??, ?? and ??). An inline function or variable shall be defined in every translation unit in which it is odr-used outside of a discarded statement.
- <sup>11</sup> Exactly one definition of a class is required in a translation unit if the class is used in a way that requires the class type to be complete. [*Example*: The following complete translation unit is well-formed, even though it never defines X:]

```
struct X;                                // declare X as a struct type
struct X* x1;                            // use X in pointer formation
X* x2;                                  // use X in pointer formation
```

---

(22) An implementation is not required to call allocation and deallocation functions from constructors or destructors; however, this is a permissible implementation technique.

— end example] [Note: The rules for declarations and expressions describe in which contexts complete class types are required. A class type T must be complete if:

- (11.1) — an object of type T is defined (??), or
- (11.2) — a non-static class data member of type T is declared (??), or
- (11.3) — T is used as the allocated type or array element type in a *new-expression* (??), or
- (11.4) — an lvalue-to-rvalue conversion is applied to a glvalue referring to an object of type T (??), or
- (11.5) — an expression is converted (either implicitly or explicitly) to type T (??, ??, ??, ??, ??), or
- (11.6) — an expression that is not a null pointer constant, and has type other than *cv void\**, is converted to the type pointer to T or reference to T using a standard conversion (??), a **dynamic\_cast** (??) or a **static\_cast** (??), or
- (11.7) — a class member access operator is applied to an expression of type T (??), or
- (11.8) — the **typeid** operator (??) or the **sizeof** operator (??) is applied to an operand of type T, or
- (11.9) — a function with a return type or argument type of type T is defined (??) or called (??), or
- (11.10) — a class with a base class of type T is defined (??), or
- (11.11) — an lvalue of type T is assigned to (??), or
- (11.12) — the type T is the subject of an **alignof** expression (??), or
- (11.13) — an *exception-declaration* has type T, reference to T, or pointer to T (??).

— end note]

- 12 There can be more than one definition of a class type (??), enumeration type (??), inline function with external linkage (??), inline variable with external linkage (??), class template (??), non-static function template (??), concept (??), static data member of a class template (??), member function of a class template (??), or template specialization for which some template parameters are not specified (??, ??) in a program provided that each definition appears in a different translation unit, and provided the definitions satisfy the following requirements. Given such an entity named D defined in more than one translation unit, then

- (12.1) — each definition of D shall consist of the same sequence of tokens; and
  - (12.2) — in each definition of D, corresponding names, looked up according to ??, shall refer to an entity defined within the definition of D, or shall refer to the same entity, after overload resolution (??) and after matching of partial template specialization (??), except that a name can refer to
    - (12.2.1) — a non-volatile const object with internal or no linkage if the object
      - (12.2.1.1) — has the same literal type in all definitions of D,
      - (12.2.1.2) — is initialized with a constant expression (??),
      - (12.2.1.3) — is not odr-used in any definition of D, and
      - (12.2.1.4) — has the same value in all definitions of D,
- or
- (12.2.2) — a reference with internal or no linkage initialized with a constant expression such that the reference refers to the same entity in all definitions of D;
- and

- (12.3) — in each definition of D, corresponding entities shall have the same language linkage; and
- (12.4) — in each definition of D, the overloaded operators referred to, the implicit calls to conversion functions, constructors, operator new functions and operator delete functions, shall refer to the same function, or to a function defined within the definition of D; and
- (12.5) — in each definition of D, a default argument used by an (implicit or explicit) function call is treated as if its token sequence were present in the definition of D; that is, the default argument is subject to the requirements described in this paragraph (and, if the default argument has subexpressions with default arguments, this requirement applies recursively)<sup>23</sup>; and
- (12.6) — if D is a class with an implicitly-declared constructor (??), it is as if the constructor was implicitly defined in every translation unit where it is odr-used, and the implicit definition in every translation unit shall call the same constructor for a subobject of D. [Example:

```
// translation unit 1:
struct X {
    X(int, int);
    X(int, int, int);
};

X::X(int, int = 0) { }

class D {
    X x = 0;
};

D d1;                                // X(int, int) called by D()
```

```
// translation unit 2:
struct X {
    X(int, int);
    X(int, int, int);
};

X::X(int, int = 0, int = 0) { }

class D {
    X x = 0;
};

D d2;                                // X(int, int, int) called by D();
                                         // D()'s implicit definition violates the ODR
```

— end example]

If D is a template and is defined in more than one translation unit, then the preceding requirements shall apply both to names from the template's enclosing scope used in the template definition (??), and also to dependent names at the point of instantiation (??). If the definitions of D satisfy all these requirements, then the behavior is as if there were a single definition of D. [Note: The entity is still declared in multiple translation units, and ?? still applies to these declarations. In particular, *lambda-expressions* (??) appearing in the type of D may result in the different declarations having distinct types. — end note] If the definitions of D do not satisfy these requirements, then the behavior is undefined.

---

<sup>23</sup>) ?? describes how default argument names are looked up.

## 6.3 Scope

[**basic.scope**]

### 6.3.1 Declarative regions and scopes

[**basic.scope.declarative**]

- <sup>1</sup> Every name is introduced in some portion of program text called a *declarative region*, which is the largest part of the program in which that name is *valid*, that is, in which that name may be used as an unqualified name to refer to the same entity. In general, each particular name is valid only within some possibly discontiguous portion of program text called its *scope*. To determine the scope of a declaration, it is sometimes convenient to refer to the *potential scope* of a declaration. The scope of a declaration is the same as its potential scope unless the potential scope contains another declaration of the same name. In that case, the potential scope of the declaration in the inner (contained) declarative region is excluded from the scope of the declaration in the outer (containing) declarative region.

- <sup>2</sup> [*Example*: In

```
int j = 24;
int main() {
    int i = j, j;
    j = 42;
}
```

the identifier *j* is declared twice as a name (and used twice). The declarative region of the first *j* includes the entire example. The potential scope of the first *j* begins immediately after that *j* and extends to the end of the program, but its (actual) scope excludes the text between the *,* and the *}*. The declarative region of the second declaration of *j* (the *j* immediately before the semicolon) includes all the text between *{* and *}*, but its potential scope excludes the declaration of *i*. The scope of the second declaration of *j* is the same as its potential scope. — *end example*]

- <sup>3</sup> The names declared by a declaration are introduced into the scope in which the declaration occurs, except that the presence of a **friend** specifier (??), certain uses of the *elaborated-type-specifier* (??), and *using-directives* (??) alter this general behavior.

- <sup>4</sup> Given a set of declarations in a single declarative region, each of which specifies the same unqualified name,

- (4.1) — they shall all refer to the same entity, or all refer to functions and function templates; or
- (4.2) — exactly one declaration shall declare a class name or enumeration name that is not a **typedef** name and the other declarations shall all refer to the same variable, non-static data member, or enumerator, or all refer to functions and function templates; in this case the class name or enumeration name is hidden (??). [*Note*: A namespace name or a class template name must be unique in its declarative region (??, ??). — *end note*]

[*Note*: These restrictions apply to the declarative region into which a name is introduced, which is not necessarily the same as the region in which the declaration occurs. In particular, *elaborated-type-specifiers* (??) and friend declarations (??) may introduce a (possibly not visible) name into an enclosing namespace; these restrictions apply to that region. Local extern declarations (??) may introduce a name into the declarative region where the declaration appears and also introduce a (possibly not visible) name into an enclosing namespace; these restrictions apply to both regions. — *end note*]

- <sup>5</sup> For a given declarative region *R* and a point *P* outside *R*, the set of *intervening* declarative regions between *P* and *R* comprises all declarative regions that are or enclose *R* and do not enclose *P*.

- <sup>6</sup> [*Note*: The name lookup rules are summarized in ?? . — *end note*]

### 6.3.2 Point of declaration

[**basic.scope.pdecl**]

- <sup>1</sup> The *point of declaration* for a name is immediately after its complete declarator (??) and before its *initializer* (if any), except as noted below. [ *Example*:

```
unsigned char x = 12;
{ unsigned char x = x; }
```

Here the second *x* is initialized with its own (indeterminate) value. — *end example*]

- <sup>2</sup> [ *Note*: A name from an outer scope remains visible up to the point of declaration of the name that hides it. [ *Example*:

```
const int i = 2;
{ int i[i]; }
```

declares a block-scope array of two integers. — *end example*] — *end note*]

- <sup>3</sup> The point of declaration for a class or class template first declared by a *class-specifier* is immediately after the *identifier* or *simple-template-id* (if any) in its *class-head* (??). The point of declaration for an enumeration is immediately after the *identifier* (if any) in either its *enum-specifier* (??) or its first *opaque-enum-declaration* (??), whichever comes first. The point of declaration of an alias or alias template immediately follows the *type-id* to which the alias refers.

- <sup>4</sup> The point of declaration of a *using-declarator* that does not name a constructor is immediately after the *using-declarator* (??).

- <sup>5</sup> The point of declaration for an enumerator is immediately after its *enumerator-definition*. [ *Example*:

```
const int x = 12;
{ enum { x = x }; }
```

Here, the enumerator *x* is initialized with the value of the constant *x*, namely 12. — *end example*]

- <sup>6</sup> After the point of declaration of a class member, the member name can be looked up in the scope of its class. [ *Note*: This is true even if the class is an incomplete class. For example,

```
struct X {
    enum E { z = 16 };
    int b[X::z];      // OK
};
```

— *end note*]

- <sup>7</sup> The point of declaration of a class first declared in an *elaborated-type-specifier* is as follows:

- (7.1) — for a declaration of the form

*class-key attribute-specifier-seq<sub>opt</sub> identifier* ;

the *identifier* is declared to be a *class-name* in the scope that contains the declaration, otherwise

- (7.2) — for an *elaborated-type-specifier* of the form

*class-key identifier*

if the *elaborated-type-specifier* is used in the *decl-specifier-seq* or *parameter-declaration-clause* of a function defined in namespace scope, the *identifier* is declared as a *class-name* in the namespace that contains the declaration; otherwise, except as a friend declaration, the *identifier* is declared in the smallest namespace or block scope that contains the declaration. [ *Note*: These rules also apply within templates. — *end note*] [ *Note*: Other forms of *elaborated-type-specifier* do not declare a new name, and therefore must refer to an existing *type-name*. See ?? and ?. — *end note*]

- <sup>8</sup> The point of declaration for an injected-class-name (??) is immediately following the opening brace of the class definition.
- <sup>9</sup> The point of declaration for a function-local predefined variable (??) is immediately before the *function-body* of a function definition.
- <sup>10</sup> The point of declaration for the variable or the structured bindings declared in the *for-range-declaration* of a range-based **for** statement (??) is immediately after the *for-range-initializer*.
- <sup>11</sup> The point of declaration for a template parameter is immediately after its complete *template-parameter*.  
[Example:

```
typedef unsigned char T;
template<class T
    = T      // lookup finds the typedef name of unsigned char
    , T      // lookup finds the template parameter
    N = 0> struct A { };

— end example]
```

- <sup>12</sup> [Note: Friend declarations refer to functions or classes that are members of the nearest enclosing namespace, but they do not introduce new names into that namespace (??). Function declarations at block scope and variable declarations with the **extern** specifier at block scope refer to declarations that are members of an enclosing namespace, but they do not introduce new names into that scope. — end note]
- <sup>13</sup> [Note: For point of instantiation of a template, see ??.— end note]

### 6.3.3 Block scope

[basic.scope.block]

- <sup>1</sup> A name declared in a block (??) is local to that block; it has *block scope*. Its potential scope begins at its point of declaration (??) and ends at the end of its block. A variable declared at block scope is a *local variable*.
- <sup>2</sup> The name declared in an *exception-declaration* is local to the *handler* and shall not be redeclared in the outermost block of the *handler*.
- <sup>3</sup> Names declared in the *init-statement*, the *for-range-declaration*, and in the *condition* of **if**, **while**, **for**, and **switch** statements are local to the **if**, **while**, **for**, or **switch** statement (including the controlled statement), and shall not be redeclared in a subsequent condition of that statement nor in the outermost block (or, for the **if** statement, any of the outermost blocks) of the controlled statement; see ??.

### 6.3.4 Function parameter scope

[basic.scope.param]

- <sup>1</sup> A function parameter (including one appearing in a *lambda-declarator*) or function-local predefined variable (??) has *function parameter scope*. The potential scope of a parameter or function-local predefined variable begins at its point of declaration. If the nearest enclosing function declarator is not the declarator of a function definition, the potential scope ends at the end of that function declarator. Otherwise, if the function has a *function-try-block* the potential scope ends at the end of the last associated handler. Otherwise the potential scope ends at the end of the outermost block of the function definition. A parameter name shall not be redeclared in the outermost block of the function definition nor in the outermost block of any handler associated with a *function-try-block*.

### 6.3.5 Function scope

[basic.funscope]

- <sup>1</sup> Labels (??) have *function scope* and may be used anywhere in the function in which they are declared. Only labels have function scope.

### 6.3.6 Namespace scope

[**basic.scope.namespace**]

- <sup>1</sup> The declarative region of a *namespace-definition* is its *namespace-body*. Entities declared in a *namespace-body* are said to be *members* of the namespace, and names introduced by these declarations into the declarative region of the namespace are said to be *member names* of the namespace. A namespace member name has namespace scope. Its potential scope includes its namespace from the name's point of declaration (??) onwards; and for each *using-directive* (??) that nominates the member's namespace, the member's potential scope includes that portion of the potential scope of the *using-directive* that follows the member's point of declaration. [Example:

```
namespace N {
    int i;
    int g(int a) { return a; }
    int j();
    void q();
}

namespace { int l=1; }
// the potential scope of l is from its point of declaration to the end of the translation unit

namespace N {
    int g(char a) { // overloads N::g(int)
        return l+a; // l is from unnamed namespace
    }

    int i;           // error: duplicate definition
    int j();         // OK: duplicate function declaration

    int j() {       // OK: definition of N::j()
        return g(i); // calls N::g(int)
    }

    int q();         // error: different return type
}

— end example ]
```

- <sup>2</sup> A namespace member can also be referred to after the `::` scope resolution operator (??) applied to the name of its namespace or the name of a namespace which nominates the member's namespace in a *using-directive*; see ??.
- <sup>3</sup> The outermost declarative region of a translation unit is also a namespace, called the *global namespace*. A name declared in the global namespace has *global namespace scope* (also called *global scope*). The potential scope of such a name begins at its point of declaration (??) and ends at the end of the translation unit that is its declarative region. A name with global namespace scope is said to be a *global name*.

### 6.3.7 Class scope

[**basic.scope.class**]

- <sup>1</sup> The potential scope of a name declared in a class consists not only of the declarative region following the name's point of declaration, but also of all function bodies, default arguments, *noexcept-specifiers*, and *brace-or-equal-initializers* of non-static data members in that class (including such things in nested classes).
- <sup>2</sup> A name `N` used in a class `S` shall refer to the same declaration in its context and when re-evaluated in the completed scope of `S`. No diagnostic is required for a violation of this rule.

- <sup>3</sup> A name declared within a member function hides a declaration of the same name whose scope extends to or past the end of the member function's class.
- <sup>4</sup> The potential scope of a declaration that extends to or past the end of a class definition also extends to the regions defined by its member definitions, even if the members are defined lexically outside the class (this includes static data member definitions, nested class definitions, and member function definitions, including the member function body and any portion of the declarator part of such definitions which follows the *declarator-id*, including a *parameter-declaration-clause* and any default arguments (??)).

<sup>5</sup> [ *Example*:

```

typedef int c;
enum { i = 1 };

class X {
    char v[i];                      // error: i refers to ::i but when reevaluated is X::i
    int f() { return sizeof(c); }     // OK: X::c
    char c;
    enum { i = 2 };
};

typedef char* T;
struct Y {
    T a;                           // error: T refers to ::T but when reevaluated is Y::T
    typedef long T;
    T b;
};

typedef int I;
class D {
    typedef I I;                  // error, even though no reordering involved
};

— end example]

```

<sup>6</sup> The name of a class member shall only be used as follows:

- (6.1) — in the scope of its class (as described above) or a class derived (??) from its class,
- (6.2) — after the . operator applied to an expression of the type of its class (??) or a class derived from its class,
- (6.3) — after the -> operator applied to a pointer to an object of its class (??) or a class derived from its class,
- (6.4) — after the :: scope resolution operator (??) applied to the name of its class or a class derived from its class.

### 6.3.8 Enumeration scope

[**basic.scope.enum**]

- <sup>1</sup> The name of a scoped enumerator (??) has *enumeration scope*. Its potential scope begins at its point of declaration and terminates at the end of the *enum-specifier*.

### 6.3.9 Template parameter scope

[**basic.scope.temp**]

- <sup>1</sup> The declarative region of the name of a template parameter of a template *template-parameter* is the smallest *template-parameter-list* in which the name was introduced.

- <sup>2</sup> The declarative region of the name of a template parameter of a template is the smallest *template-declaration* in which the name was introduced. Only template parameter names belong to this declarative region; any other kind of name introduced by the *declaration* of a *template-declaration* is instead introduced into the same declarative region where it would be introduced as a result of a non-template declaration of the same name. [ *Example*:

```
namespace N {
    template<class T> struct A { }; // #1
    template<class U> void f(U) { } // #2
    struct B {
        template<class V> friend int g(struct C*); // #3
    };
}
```

The declarative regions of T, U and V are the *template-declarations* on lines #1, #2, and #3, respectively. But the names A, f, g and C all belong to the same declarative region — namely, the *namespace-body* of N. (g is still considered to belong to this declarative region in spite of its being hidden during qualified and unqualified name lookup.) — *end example* ]

- <sup>3</sup> The potential scope of a template parameter name begins at its point of declaration (??) and ends at the end of its declarative region. [ *Note*: This implies that a *template-parameter* can be used in the declaration of subsequent *template-parameters* and their default arguments but cannot be used in preceding *template-parameters* or their default arguments. For example,

```
template<class T, T* p, class U = T> class X { /* ... */ };
template<class T> void f(T* p = new T);
```

This also implies that a *template-parameter* can be used in the specification of base classes. For example,

```
template<class T> class X : public Array<T> { /* ... */ };
template<class T> class Y : public T { /* ... */ };
```

The use of a template parameter as a base class implies that a class used as a template argument must be defined and not just declared when the class template is instantiated. — *end note* ]

- <sup>4</sup> The declarative region of the name of a template parameter is nested within the immediately-enclosing declarative region. [ *Note*: As a result, a *template-parameter* hides any entity with the same name in an enclosing scope (??). [ *Example*:

```
typedef int N;
template<N X, typename N, template<N Y> class T> struct A;
```

Here, X is a non-type template parameter of type int and Y is a non-type template parameter of the same type as the second template parameter of A. — *end example*] — *end note* ]

- <sup>5</sup> [ *Note*: Because the name of a template parameter cannot be redeclared within its potential scope (??), a template parameter's scope is often its potential scope. However, it is still possible for a template parameter name to be hidden; see ??]. — *end note* ]

### 6.3.10 Name hiding

[**basic.scope.hiding**]

- <sup>1</sup> A name can be hidden by an explicit declaration of that same name in a nested declarative region or derived class (??).
- <sup>2</sup> A class name (??) or enumeration name (??) can be hidden by the name of a variable, data member, function, or enumerator declared in the same scope. If a class or enumeration name and a variable, data member,

function, or enumerator are declared in the same scope (in any order) with the same name, the class or enumeration name is hidden wherever the variable, data member, function, or enumerator name is visible.

- 3 In a member function definition, the declaration of a name at block scope hides the declaration of a member of the class with the same name; see [??](#). The declaration of a member in a derived class ([??](#)) hides the declaration of a member of a base class of the same name; see [??](#).
- 4 During the lookup of a name qualified by a namespace name, declarations that would otherwise be made visible by a *using-directive* can be hidden by declarations with the same name in the namespace containing the *using-directive*; see [??](#).
- 5 If a name is in scope and is not hidden it is said to be *visible*.

## 6.4 Name lookup

[[basic.lookup](#)]

- 1 The name lookup rules apply uniformly to all names (including *typedef-names* ([??](#)), *namespace-names* ([??](#)), and *class-names* ([??](#))) wherever the grammar allows such names in the context discussed by a particular rule. Name lookup associates the use of a name with a set of declarations ([??](#)) of that name. The declarations found by name lookup shall either all declare the same entity or shall all declare functions; in the latter case, the declarations are said to form a set of overloaded functions ([??](#)). Overload resolution ([??](#)) takes place after name lookup has succeeded. The access rules ([??](#)) are considered only once name lookup and function overload resolution (if applicable) have succeeded. Only after name lookup, function overload resolution (if applicable) and access checking have succeeded are the attributes introduced by the name's declaration used further in expression processing ([??](#)).
- 2 A name “looked up in the context of an expression” is looked up as an unqualified name in the scope where the expression is found.
- 3 The injected-class-name of a class ([??](#)) is also considered to be a member of that class for the purposes of name hiding and lookup.
- 4 [ *Note:* [??](#) discusses linkage issues. The notions of scope, point of declaration and name hiding are discussed in [??](#). — *end note* ]

### 6.4.1 Unqualified name lookup

[[basic.lookup.unqual](#)]

- 1 In all the cases listed in [??](#), the scopes are searched for a declaration in the order listed in each of the respective categories; name lookup ends as soon as a declaration is found for the name. If no declaration is found, the program is ill-formed.
- 2 The declarations from the namespace nominated by a *using-directive* become visible in a namespace enclosing the *using-directive*; see [??](#). For the purpose of the unqualified name lookup rules described in [??](#), the declarations from the namespace nominated by the *using-directive* are considered members of that enclosing namespace.
- 3 The lookup for an unqualified name used as the *postfix-expression* of a function call is described in [??](#). [ *Note:* For purposes of determining (during parsing) whether an expression is a *postfix-expression* for a function call, the usual name lookup rules apply. In some cases a name followed by < is treated as a *template-name* even though name lookup did not find a *template-name* (see [??](#)). For example,

```
int h;
void g();
namespace N {
    struct A {};
    template <class T> int f(T);
```

```

template <class T> int g(T);
template <class T> int h(T);
}

int x = f<N::A>(N::A());           // OK: lookup of f finds nothing, f treated as template name
int y = g<N::A>(N::A());           // OK: lookup of g finds a function, g treated as template name
int z = h<N::A>(N::A());           // error: h< does not begin a template-id

```

The rules in ?? have no effect on the syntactic interpretation of an expression. For example,

```

typedef int f;
namespace N {
    struct A {
        friend void f(A &);
        operator int();
        void g(A a) {
            int i = f(a);           // f is the typedef, not the friend function: equivalent to int(a)
        }
    };
}

```

Because the expression is not a function call, the argument-dependent name lookup (??) does not apply and the friend function `f` is not found. —end note]

- <sup>4</sup> A name used in global scope, outside of any function, class or user-declared namespace, shall be declared before its use in global scope.
- <sup>5</sup> A name used in a user-declared namespace outside of the definition of any function or class shall be declared before its use in that namespace or before its use in a namespace enclosing its namespace.
- <sup>6</sup> In the definition of a function that is a member of namespace `N`, a name used after the function's *declarator-id*<sup>24</sup> shall be declared before its use in the block in which it is used or in one of its enclosing blocks (??) or shall be declared before its use in namespace `N` or, if `N` is a nested namespace, shall be declared before its use in one of `N`'s enclosing namespaces. [ *Example*:

```

namespace A {
    namespace N {
        void f();
    }
}
void A::N::f() {
    i = 5;
    // The following scopes are searched for a declaration of i:
    // 1) outermost block scope of A::N::f, before the use of i
    // 2) scope of namespace N
    // 3) scope of namespace A
    // 4) global scope, before the definition of A::N::f
}

```

—end example]

---

<sup>24</sup>) This refers to unqualified names that occur, for instance, in a type or default argument in the *parameter-declaration-clause* or used in the function body.

<sup>7</sup> A name used in the definition of a class X outside of a member function body, default argument, *noexcept-specifier*, *brace-or-equal-initializer* of a non-static data member, or nested class definition<sup>25</sup> shall be declared in one of the following ways:

- (7.1) — before its use in class X or be a member of a base class of X (??), or
- (7.2) — if X is a nested class of class Y (??), before the definition of X in Y, or shall be a member of a base class of Y (this lookup applies in turn to Y's enclosing classes, starting with the innermost enclosing class),<sup>26</sup> or
- (7.3) — if X is a local class (??) or is a nested class of a local class, before the definition of class X in a block enclosing the definition of class X, or
- (7.4) — if X is a member of namespace N, or is a nested class of a class that is a member of N, or is a local class or a nested class within a local class of a function that is a member of N, before the definition of class X in namespace N or in one of N's enclosing namespaces.

[Example:

```
namespace M {
    class B {};
}

namespace N {
    class Y : public M::B {
        class X {
            int a[i];
        };
    };
}

// The following scopes are searched for a declaration of i:
// 1) scope of class N::Y::X, before the use of i
// 2) scope of class N::Y, before the definition of N::Y::X
// 3) scope of N::Y's base class M::B
// 4) scope of namespace N, before the definition of N::Y
// 5) global scope, before the definition of N
```

— end example] [Note: When looking for a prior declaration of a class or function introduced by a friend declaration, scopes outside of the innermost enclosing namespace scope are not considered; see ??.—end note] [Note: ?? further describes the restrictions on the use of names in a class definition. ?? further describes the restrictions on the use of names in nested class definitions. ?? further describes the restrictions on the use of names in local class definitions. —end note]

<sup>8</sup> For the members of a class X, a name used in a member function body, in a default argument, in a *noexcept-specifier*, in the *brace-or-equal-initializer* of a non-static data member (??), or in the definition of a class member outside of the definition of X, following the member's *declarator-id*<sup>27</sup>, shall be declared in one of the following ways:

- (8.1) — before its use in the block in which it is used or in an enclosing block (??), or

<sup>25</sup> This refers to unqualified names following the class name; such a name may be used in the *base-clause* or may be used in the class definition.

<sup>26</sup> This lookup applies whether the definition of X is nested within Y's definition or whether X's definition appears in a namespace scope enclosing Y's definition (??).

<sup>27</sup> That is, an unqualified name that occurs, for instance, in a type in the *parameter-declaration-clause* or in the *noexcept-specifier*.

- (8.2) — shall be a member of class X or be a member of a base class of X (??), or
- (8.3) — if X is a nested class of class Y (??), shall be a member of Y, or shall be a member of a base class of Y (this lookup applies in turn to Y's enclosing classes, starting with the innermost enclosing class),<sup>28</sup> or
- (8.4) — if X is a local class (??) or is a nested class of a local class, before the definition of class X in a block enclosing the definition of class X, or
- (8.5) — if X is a member of namespace N, or is a nested class of a class that is a member of N, or is a local class or a nested class within a local class of a function that is a member of N, before the use of the name, in namespace N or in one of N's enclosing namespaces.

[Example:

```
class B {};
namespace M {
    namespace N {
        class X : public B {
            void f();
        };
    }
}
void M::N::X::f() {
    i = 16;
}
```

```
// The following scopes are searched for a declaration of i:
// 1) outermost block scope of M::N::X::f, before the use of i
// 2) scope of class M::N::X
// 3) scope of M::N::X's base class B
// 4) scope of namespace M::N
// 5) scope of namespace M
// 6) global scope, before the definition of M::N::X::f
```

—end example] [Note: ?? and ?? further describe the restrictions on the use of names in member function definitions. ?? further describes the restrictions on the use of names in the scope of nested classes. ?? further describes the restrictions on the use of names in local class definitions. —end note]

- 9 Name lookup for a name used in the definition of a friend function (??) defined inline in the class granting friendship shall proceed as described for lookup in member function definitions. If the friend function is not defined in the class granting friendship, name lookup in the friend function definition shall proceed as described for lookup in namespace member function definitions.
- 10 In a friend declaration naming a member function, a name used in the function declarator and not part of a *template-argument* in the *declarator-id* is first looked up in the scope of the member function's class (??). If it is not found, or if the name is part of a *template-argument* in the *declarator-id*, the look up is as described for unqualified names in the definition of the class granting friendship. [Example:

```
struct A {
    typedef int AT;
    void f1(AT);
    void f2(float);
```

---

<sup>28</sup>) This lookup applies whether the member function is defined within the definition of class X or whether the member function is defined in a namespace scope enclosing X's definition.

```

    template <class T> void f3();
};

struct B {
    typedef char AT;
    typedef float BT;
    friend void A::f1(AT);      // parameter type is A::AT
    friend void A::f2(BT);      // parameter type is B::BT
    friend void A::f3<AT>();   // template argument is B::AT
};

— end example]

```

- <sup>11</sup> During the lookup for a name used as a default argument (??) in a function *parameter-declaration-clause* or used in the *expression* of a *mem-initializer* for a constructor (??), the function parameter names are visible and hide the names of entities declared in the block, class or namespace scopes containing the function declaration. [Note: ?? further describes the restrictions on the use of names in default arguments. ?? further describes the restrictions on the use of names in a *ctor-initializer*. — end note]
- <sup>12</sup> During the lookup of a name used in the *constant-expression* of an *enumerator-definition*, previously declared *enumerators* of the enumeration are visible and hide the names of entities declared in the block, class, or namespace scopes containing the *enum-specifier*.
- <sup>13</sup> A name used in the definition of a **static** data member of class X (??) (after the *qualified-id* of the static member) is looked up as if the name was used in a member function of X. [Note: ?? further describes the restrictions on the use of names in the definition of a **static** data member. — end note]
- <sup>14</sup> If a variable member of a namespace is defined outside of the scope of its namespace then any name that appears in the definition of the member (after the *declarator-id*) is looked up as if the definition of the member occurred in its namespace. [Example:

```

namespace N {
    int i = 4;
    extern int j;
}

int i = 2;

int N::j = i;      // N::j == 4
— end example]

```

- <sup>15</sup> A name used in the handler for a *function-try-block* (??) is looked up as if the name was used in the outermost block of the function definition. In particular, the function parameter names shall not be redeclared in the *exception-declaration* nor in the outermost block of a handler for the *function-try-block*. Names declared in the outermost block of the function definition are not found when looked up in the scope of a handler for the *function-try-block*. [Note: But function parameter names are found. — end note]
- <sup>16</sup> [Note: The rules for name lookup in template definitions are described in ?. — end note]

#### 6.4.2 Argument-dependent name lookup

[basic.lookup.argdep]

- <sup>1</sup> When the *postfix-expression* in a function call (??) is an *unqualified-id*, other namespaces not considered during the usual unqualified lookup (??) may be searched, and in those namespaces, namespace-scope friend function or function template declarations (??) not otherwise visible may be found. These modifications to

the search depend on the types of the arguments (and for template template arguments, the namespace of the template argument). [ *Example*:

```
namespace N {
    struct S { };
    void f(S);
}

void g() {
    N::S s;
    f(s);           // OK: calls N::f
    (f)(s);         // error: N::f not considered; parentheses prevent argument-dependent lookup
}
```

— *end example* ]

- 2 For each argument type T in the function call, there is a set of zero or more *associated namespaces* and a set of zero or more *associated classes* to be considered. The sets of namespaces and classes are determined entirely by the types of the function arguments (and the namespace of any template template argument). Typedef names and *using-declarations* used to specify the types do not contribute to this set. The sets of namespaces and classes are determined in the following way:

- (2.1) — If T is a fundamental type, its associated sets of namespaces and classes are both empty.
- (2.2) — If T is a class type (including unions), its associated classes are: the class itself; the class of which it is a member, if any; and its direct and indirect base classes. Its associated namespaces are the innermost enclosing namespaces of its associated classes. Furthermore, if T is a class template specialization, its associated namespaces and classes also include: the namespaces and classes associated with the types of the template arguments provided for template type parameters (excluding template template parameters); the namespaces of which any template template arguments are members; and the classes of which any member templates used as template template arguments are members. [ *Note*: Non-type template arguments do not contribute to the set of associated namespaces. — *end note* ]
- (2.3) — If T is an enumeration type, its associated namespace is the innermost enclosing namespace of its declaration. If it is a class member, its associated class is the member's class; else it has no associated class.
- (2.4) — If T is a pointer to U or an array of U, its associated namespaces and classes are those associated with U.
- (2.5) — If T is a function type, its associated namespaces and classes are those associated with the function parameter types and those associated with the return type.
- (2.6) — If T is a pointer to a member function of a class X, its associated namespaces and classes are those associated with the function parameter types and return type, together with those associated with X.
- (2.7) — If T is a pointer to a data member of class X, its associated namespaces and classes are those associated with the member type together with those associated with X.

If an associated namespace is an inline namespace (??), its enclosing namespace is also included in the set. If an associated namespace directly contains inline namespaces, those inline namespaces are also included in the set. In addition, if the argument is the name or address of a set of overloaded functions and/or function templates, its associated classes and namespaces are the union of those associated with each of the members of the set, i.e., the classes and namespaces associated with its parameter types and return type. Additionally,

if the aforementioned set of overloaded functions is named with a *template-id*, its associated classes and namespaces also include those of its type *template-arguments* and its template *template-arguments*.

- <sup>3</sup> Let  $X$  be the lookup set produced by unqualified lookup (??) and let  $Y$  be the lookup set produced by argument dependent lookup (defined as follows). If  $X$  contains

- (3.1) — a declaration of a class member, or
- (3.2) — a block-scope function declaration that is not a *using-declaration*, or
- (3.3) — a declaration that is neither a function nor a function template

then  $Y$  is empty. Otherwise  $Y$  is the set of declarations found in the namespaces associated with the argument types as described below. The set of declarations found by the lookup of the name is the union of  $X$  and  $Y$ . [ *Note*: The namespaces and classes associated with the argument types can include namespaces and classes already considered by the ordinary unqualified lookup. — *end note* ] [ *Example*:

```
namespace NS {
    class T { };
    void f(T);
    void g(T, int);
}
NS::T parm;
void g(NS::T, float);
int main() {
    f(parm);                                // OK: calls NS::f
    extern void g(NS::T, float);
    g(parm, 1);                            // OK: calls g(NS::T, float)
}
```

— *end example* ]

- <sup>4</sup> When considering an associated namespace, the lookup is the same as the lookup performed when the associated namespace is used as a qualifier (??) except that:

- (4.1) — Any *using-directives* in the associated namespace are ignored.
- (4.2) — Any namespace-scope friend functions or friend function templates (??) declared in associated classes are visible within their respective namespaces even if they are not visible during an ordinary lookup (??).
- (4.3) — All names except those of (possibly overloaded) functions and function templates are ignored.

### 6.4.3 Qualified name lookup

[**basic.lookup.qual**]

- <sup>1</sup> The name of a class or namespace member or enumerator can be referred to after the `::` scope resolution operator (??) applied to a *nested-name-specifier* that denotes its class, namespace, or enumeration. If a `::` scope resolution operator in a *nested-name-specifier* is not preceded by a *decltype-specifier*, lookup of the name preceding that `::` considers only namespaces, types, and templates whose specializations are types. If the name found does not designate a namespace or a class, enumeration, or dependent type, the program is ill-formed. [ *Example*:

```
class A {
public:
    static int n;
};
int main() {
    int A;
```

```

A::n = 42;           // OK
A b;                // ill-formed: A does not name a type
}

— end example]

```

- 2 [Note: Multiply qualified names, such as N1::N2::N3::n, can be used to refer to members of nested classes (??) or members of nested namespaces. —end note]
- 3 In a declaration in which the *declarator-id* is a *qualified-id*, names used before the *qualified-id* being declared are looked up in the defining namespace scope; names following the *qualified-id* are looked up in the scope of the member's class or namespace. [Example:

```

class X {};
class C {
    class X {};
    static const int number = 50;
    static X arr[number];
};

X C::arr[number]; // ill-formed:
// equivalent to ::X C::arr[C::number];
// and not to C::X C::arr[C::number];

```

— end example]

- 4 A name prefixed by the unary scope operator :: (??) is looked up in global scope, in the translation unit where it is used. The name shall be declared in global namespace scope or shall be a name whose declaration is visible in global scope because of a *using-directive* (??). The use of :: allows a global name to be referred to even if its identifier has been hidden (??).
- 5 A name prefixed by a *nested-name-specifier* that nominates an enumeration type shall represent an *enumerator* of that enumeration.
- 6 If a *pseudo-destructor-name* (??) contains a *nested-name-specifier*, the *type-names* are looked up as types in the scope designated by the *nested-name-specifier*. Similarly, in a *qualified-id* of the form:

*nested-name-specifier<sub>opt</sub>* *class-name* :: ~ *class-name*

the second *class-name* is looked up in the same scope as the first. [Example:

```

struct C {
    typedef int I;
};

typedef int I1, I2;
extern int* p;
extern int* q;
p->C::I::~I();      // I is looked up in the scope of C
q->I1::~I2();        // I2 is looked up in the scope of the postfix-expression

struct A {
    ~A();
};

typedef A AB;
int main() {
    AB* p;
}

```

```
p->AB::~AB();      // explicitly calls the destructor for A
}

— end example] [Note: ?? describes how name lookup proceeds after the . and -> operators. — end note]
```

#### 6.4.3.1 Class members

[class.qual]

- 1 If the *nested-name-specifier* of a *qualified-id* nominates a class, the name specified after the *nested-name-specifier* is looked up in the scope of the class (??), except for the cases listed below. The name shall represent one or more members of that class or of one of its base classes (??). [Note: A class member can be referred to using a *qualified-id* at any point in its potential scope (??). — end note] The exceptions to the name lookup rule above are the following:
  - (1.1) — the lookup for a destructor is as specified in ??;
  - (1.2) — a *conversion-type-id* of a *conversion-function-id* is looked up in the same manner as a *conversion-type-id* in a class member access (see ??);
  - (1.3) — the names in a *template-argument* of a *template-id* are looked up in the context in which the entire *postfix-expression* occurs.
  - (1.4) — the lookup for a name specified in a *using-declaration* (??) also finds class or enumeration names hidden within the same scope (??).

- 2 In a lookup in which function names are not ignored<sup>29</sup> and the *nested-name-specifier* nominates a class C:
  - (2.1) — if the name specified after the *nested-name-specifier*, when looked up in C, is the injected-class-name of C (??), or
  - (2.2) — in a *using-declarator* of a *using-declaration* (??) that is a *member-declaration*, if the name specified after the *nested-name-specifier* is the same as the *identifier* or the *simple-template-id*'s *template-name* in the last component of the *nested-name-specifier*,

the name is instead considered to name the constructor of class C. [Note: For example, the constructor is not an acceptable lookup result in an *elaborated-type-specifier* so the constructor would not be used in place of the injected-class-name. — end note] Such a constructor name shall be used only in the *declarator-id* of a declaration that names a constructor or in a *using-declaration*. [Example:

```
struct A { A(); };
struct B: public A { B(); };

A::A() { }
B::B() { }

B::A ba;           // object of type A
A::A a;           // error, A::A is not a type name
struct A::A a2;   // object of type A
```

— end example]

- 3 A class member name hidden by a name in a nested declarative region or by the name of a derived class member can still be found if qualified by the name of its class followed by the :: operator.

---

<sup>29</sup> Lookups in which function names are ignored include names appearing in a *nested-name-specifier*, an *elaborated-type-specifier*, or a *base-specifier*.

### 6.4.3.2 Namespace members

[namespace.qual]

- <sup>1</sup> If the *nested-name-specifier* of a *qualified-id* nominates a namespace (including the case where the *nested-name-specifier* is `::`, i.e., nominating the global namespace), the name specified after the *nested-name-specifier* is looked up in the scope of the namespace. The names in a *template-argument* of a *template-id* are looked up in the context in which the entire *postfix-expression* occurs.
- <sup>2</sup> For a namespace `X` and name `m`, the namespace-qualified lookup set  $S(X, m)$  is defined as follows: Let  $S'(X, m)$  be the set of all declarations of `m` in `X` and the inline namespace set of `X` (??). If  $S'(X, m)$  is not empty,  $S(X, m)$  is  $S'(X, m)$ ; otherwise,  $S(X, m)$  is the union of  $S(N_i, m)$  for all namespaces  $N_i$  nominated by *using-directives* in `X` and its inline namespace set.
- <sup>3</sup> Given `X::m` (where `X` is a user-declared namespace), or given `::m` (where `X` is the global namespace), if  $S(X, m)$  is the empty set, the program is ill-formed. Otherwise, if  $S(X, m)$  has exactly one member, or if the context of the reference is a *using-declaration* (??),  $S(X, m)$  is the required set of declarations of `m`. Otherwise if the use of `m` is not one that allows a unique declaration to be chosen from  $S(X, m)$ , the program is ill-formed. [Example:

```

int x;
namespace Y {
    void f(float);
    void h(int);
}

namespace Z {
    void h(double);
}

namespace A {
    using namespace Y;
    void f(int);
    void g(int);
    int i;
}

namespace B {
    using namespace Z;
    void f(char);
    int i;
}

namespace AB {
    using namespace A;
    using namespace B;
    void g();
}

void h()
{
    AB::g();           // g is declared directly in AB, therefore S is {AB::g()} and AB::g() is chosen
}

```

```

AB::f(1);           // f is not declared directly in AB so the rules are applied recursively to A and B;
                    // namespace Y is not searched and Y::f(float) is not considered;
                    // S is {A::f(int),B::f(char)} and overload resolution chooses A::f(int)

AB::f('c');        // as above but resolution chooses B::f(char)

AB::x++;           // x is not declared directly in AB, and is not declared in A or B, so the rules
                    // are applied recursively to Y and Z, S is {} so the program is ill-formed

AB::i++;           // i is not declared directly in AB so the rules are applied recursively to A and B,
                    // S is {A::i,B::i} so the use is ambiguous and the program is ill-formed

AB::h(16.8);       // h is not declared directly in AB and not declared directly in A or B so the rules
                    // are applied recursively to Y and Z, S is {Y::h(int),Z::h(double)} and
                    // overload resolution chooses Z::h(double)

}

— end example ]

```

- <sup>4</sup> [Note: The same declaration found more than once is not an ambiguity (because it is still a unique declaration).  
 [Example:

```

namespace A {
    int a;
}

namespace B {
    using namespace A;
}

namespace C {
    using namespace A;
}

namespace BC {
    using namespace B;
    using namespace C;
}

void f()
{
    BC::a++;           // OK: S is {A::a,A::a}
}

namespace D {
    using A::a;
}

namespace BD {
    using namespace B;
}

```

```

    using namespace D;
}

void g()
{
    BD::a++;           // OK: S is {A::a,A::a}
}

— end example] — end note]
```

- <sup>5</sup> [Example: Because each referenced namespace is searched at most once, the following is well-defined:

```

namespace B {
    int b;
}

namespace A {
    using namespace B;
    int a;
}

namespace B {
    using namespace A;
}

void f()
{
    A::a++;           // OK: a declared directly in A, S is {A::a}
    B::a++;           // OK: both A and B searched (once), S is {A::a}
    A::b++;           // OK: both A and B searched (once), S is {B::b}
    B::b++;           // OK: b declared directly in B, S is {B::b}
}

— end example]
```

- <sup>6</sup> During the lookup of a qualified namespace member name, if the lookup finds more than one declaration of the member, and if one declaration introduces a class name or enumeration name and the other declarations either introduce the same variable, the same enumerator or a set of functions, the non-type name hides the class or enumeration name if and only if the declarations are from the same namespace; otherwise (the declarations are from different namespaces), the program is ill-formed. [Example:

```

namespace A {
    struct x { };
    int x;
    int y;
}

namespace B {
    struct y { };
}

namespace C {
    using namespace A;
```

```

using namespace B;
int i = C::x;      // OK, A::x (of type int)
int j = C::y;      // ambiguous, A::y or B::y
}
— end example]

```

- 7 In a declaration for a namespace member in which the *declarator-id* is a *qualified-id*, given that the *qualified-id* for the namespace member has the form

*nested-name-specifier unqualified-id*

the *unqualified-id* shall name a member of the namespace designated by the *nested-name-specifier* or of an element of the inline namespace set (??) of that namespace. [Example:

```

namespace A {
    namespace B {
        void f1(int);
    }
    using namespace B;
}
void A::f1(int){ } // ill-formed, f1 is not a member of A

```

— end example] However, in such namespace member declarations, the *nested-name-specifier* may rely on *using-directives* to implicitly provide the initial part of the *nested-name-specifier*. [Example:

```

namespace A {
    namespace B {
        void f1(int);
    }
}

namespace C {
    namespace D {
        void f1(int);
    }
}

using namespace A;
using namespace C::D;
void B::f1(int){ } // OK, defines A::B::f1(int)

```

— end example]

#### 6.4.4 Elaborated type specifiers

[[basic.lookup.elab](#)]

- 1 An *elaborated-type-specifier* (??) may be used to refer to a previously declared *class-name* or *enum-name* even though the name has been hidden by a non-type declaration (??).
- 2 If the *elaborated-type-specifier* has no *nested-name-specifier*, and unless the *elaborated-type-specifier* appears in a declaration with the following form:

*class-key attribute-specifier-seq<sub>opt</sub> identifier ;*

the *identifier* is looked up according to ?? but ignoring any non-type names that have been declared. If the *elaborated-type-specifier* is introduced by the `enum` keyword and this lookup does not find a previously declared *type-name*, the *elaborated-type-specifier* is ill-formed. If the *elaborated-type-specifier* is introduced by

the *class-key* and this lookup does not find a previously declared *type-name*, or if the *elaborated-type-specifier* appears in a declaration with the form:

*class-key attribute-specifier-seq<sub>opt</sub>* *identifier* ;

the *elaborated-type-specifier* is a declaration that introduces the *class-name* as described in ??.

- 3 If the *elaborated-type-specifier* has a *nested-name-specifier*, qualified name lookup is performed, as described in ??, but ignoring any non-type names that have been declared. If the name lookup does not find a previously declared *type-name*, the *elaborated-type-specifier* is ill-formed. [Example:

```
struct Node {
    struct Node* Next;           // OK: Refers to Node at global scope
    struct Data* Data;          // OK: Declares type Data at global scope and member Data
};

struct Data {
    struct Node* Node;          // OK: Refers to Node at global scope
    friend struct ::Glob;        // error: Glob is not declared, cannot introduce a qualified type (?)
    friend struct Glob;         // OK: Refers to (as yet) undeclared Glob at global scope.
    /* ... */
};

struct Base {
    struct Data;                // OK: Declares nested Data
    struct ::Data* thatData;     // OK: Refers to ::Data
    struct Base::Data* thisData; // OK: Refers to nested Data
    friend class ::Data;         // OK: global Data is a friend
    friend class Data;           // OK: nested Data is a friend
    struct Data { /* ... */ };   // Defines nested Data
};

struct Data;                  // OK: Redefines Data at global scope
struct ::Data;                // error: cannot introduce a qualified type (?)
struct Base::Data;            // error: cannot introduce a qualified type (?)
struct Base::Datum;           // error: Datum undefined
struct Base::Data* pBase;      // OK: refers to nested Data

— end example ]
```

#### 6.4.5 Class member access

[**basic.lookup.classref**]

- <sup>1</sup> In a class member access expression (??), if the . or -> token is immediately followed by an *identifier* followed by a <, the identifier must be looked up to determine whether the < is the beginning of a template argument list (??) or a less-than operator. The identifier is first looked up in the class of the object expression. If the identifier is not found, it is then looked up in the context of the entire *postfix-expression* and shall name a class template.
- <sup>2</sup> If the *id-expression* in a class member access (??) is an *unqualified-id*, and the type of the object expression is of a class type C, the *unqualified-id* is looked up in the scope of class C. For a pseudo-destructor call (??), the *unqualified-id* is looked up in the context of the complete *postfix-expression*.

- <sup>3</sup> If the *unqualified-id* is  $\sim$ *type-name*, the *type-name* is looked up in the context of the entire *postfix-expression*. If the type T of the object expression is of a class type C, the *type-name* is also looked up in the scope of class C. At least one of the lookups shall find a name that refers to cv T. [Example:

```
struct A { };

struct B {
    struct A { };
    void f(::A* a);
};

void B::f(::A* a) {
    a->~A(); // OK: lookup in *a finds the injected-class-name
}
```

— end example]

- <sup>4</sup> If the *id-expression* in a class member access is a *qualified-id* of the form

```
class-name-or-namespace-name :: ...
```

the *class-name-or-namespace-name* following the . or -> operator is first looked up in the class of the object expression and the name, if found, is used. Otherwise it is looked up in the context of the entire *postfix-expression*. [Note: See ??, which describes the lookup of a name before ::, which will only find a type or namespace name. — end note]

- <sup>5</sup> If the *qualified-id* has the form

```
:: class-name-or-namespace-name :: ...
```

the *class-name-or-namespace-name* is looked up in global scope as a *class-name* or *namespace-name*.

- <sup>6</sup> If the *nested-name-specifier* contains a *simple-template-id* (??), the names in its *template-arguments* are looked up in the context in which the entire *postfix-expression* occurs.

- <sup>7</sup> If the *id-expression* is a *conversion-function-id*, its *conversion-type-id* is first looked up in the class of the object expression and the name, if found, is used. Otherwise it is looked up in the context of the entire *postfix-expression*. In each of these lookups, only names that denote types or templates whose specializations are types are considered. [Example:

```
struct A { };

namespace N {
    struct A {
        void g() { }
        template <class T> operator T();
    };
}

int main() {
    N::A a;
    a.operator A(); // calls N::A::operator N::A
}
```

— end example]

#### 6.4.6 Using-directives and namespace aliases

[**basic.lookup.udir**]

- <sup>1</sup> In a *using-directive* or *namespace-alias-definition*, during the lookup for a *namespace-name* or for a name in a *nested-name-specifier* only namespace names are considered.

#### 6.5 Program and linkage

[**basic.link**]

- <sup>1</sup> A *program* consists of one or more *translation units* (??) linked together. A translation unit consists of a sequence of declarations.

*translation-unit*:

*declaration-seq<sub>opt</sub>*

- <sup>2</sup> A name is said to have *linkage* when it might denote the same object, reference, function, type, template, namespace or value as a name introduced by a declaration in another scope:

(2.1) — When a name has *external linkage*, the entity it denotes can be referred to by names from scopes of other translation units or from other scopes of the same translation unit.

(2.2) — When a name has *internal linkage*, the entity it denotes can be referred to by names from other scopes in the same translation unit.

(2.3) — When a name has *no linkage*, the entity it denotes cannot be referred to by names from other scopes.

- <sup>3</sup> A name having namespace scope (??) has internal linkage if it is the name of

(3.1) — a variable, function or function template that is explicitly declared **static**; or,

(3.2) — a non-inline variable of non-volatile const-qualified type that is neither explicitly declared **extern** nor previously declared to have external linkage; or

(3.3) — a data member of an anonymous union.

- <sup>4</sup> An unnamed namespace or a namespace declared directly or indirectly within an unnamed namespace has internal linkage. All other namespaces have external linkage. A name having namespace scope that has not been given internal linkage above has the same linkage as the enclosing namespace if it is the name of

(4.1) — a variable; or

(4.2) — a function; or

(4.3) — a named class (??), or an unnamed class defined in a **typedef** declaration in which the class has the **typedef** name for linkage purposes (??); or

(4.4) — a named enumeration (??), or an unnamed enumeration defined in a **typedef** declaration in which the enumeration has the **typedef** name for linkage purposes (??); or

(4.5) — a template.

- <sup>5</sup> In addition, a member function, static data member, a named class or enumeration of class scope, or an unnamed class or enumeration defined in a class-scope **typedef** declaration such that the class or enumeration has the **typedef** name for linkage purposes (??), has the same linkage, if any, as the name of the class of which it is a member.

- <sup>6</sup> The name of a function declared in block scope and the name of a variable declared by a block scope **extern** declaration have linkage. If there is a visible declaration of an entity with linkage having the same name and type, ignoring entities declared outside the innermost enclosing namespace scope, the block scope declaration declares that same entity and receives the linkage of the previous declaration. If there is more than one such matching entity, the program is ill-formed. Otherwise, if no matching entity is found, the block scope entity

receives external linkage. If, within a translation unit, the same entity is declared with both internal and external linkage, the program is ill-formed. [ *Example*:

```
static void f();
static int i = 0;                                // #1
void g() {
    extern void f();                            // internal linkage
    int i;                                     // #2: i has no linkage
    {
        extern void f();                      // internal linkage
        extern int i;                         // #3: external linkage, ill-formed
    }
}
```

Without the declaration at line #2, the declaration at line #3 would link with the declaration at line #1. Because the declaration with internal linkage is hidden, however, #3 is given external linkage, making the program ill-formed. — *end example* ]

- 7 When a block scope declaration of an entity with linkage is not found to refer to some other declaration, then that entity is a member of the innermost enclosing namespace. However such a declaration does not introduce the member name in its namespace scope. [ *Example*:

```
namespace X {
    void p() {
        q();                                // error: q not yet declared
        extern void q();                     // q is a member of namespace X
    }

    void middle() {
        q();                                // error: q not yet declared
    }

    void q() { /* ... */ }                // definition of X::q
}

void q() { /* ... */ }                    // some other, unrelated q
— end example ]
```

- 8 Names not covered by these rules have no linkage. Moreover, except as noted, a name declared at block scope (??) has no linkage.

- 9 A type is said to have linkage if and only if:

- (9.1) — it is a class or enumeration type that is named (or has a name for linkage purposes (??)) and the name has linkage; or
- (9.2) — it is an unnamed class or unnamed enumeration that is a member of a class with linkage; or
- (9.3) — it is a specialization of a class template (??)<sup>30</sup>; or
- (9.4) — it is a fundamental type (??); or
- (9.5) — it is a compound type (??) other than a class or enumeration, compounded exclusively from types that have linkage; or

<sup>30</sup>) A class template has the linkage of the innermost enclosing class or namespace in which it is declared.

- (9.6) — it is a cv-qualified (??) version of a type that has linkage.

A type without linkage shall not be used as the type of a variable or function with external linkage unless

- (9.7) — the entity has C language linkage (??), or

- (9.8) — the entity is not odr-used (??) or is defined in the same translation unit.

[*Note*: In other words, a type without linkage contains a class or enumeration that cannot be named outside its translation unit. An entity with external linkage declared using such a type could not correspond to any other entity in another translation unit of the program and thus must be defined in the translation unit if it is odr-used. Also note that classes with linkage may contain members whose types do not have linkage, and that typedef names are ignored in the determination of whether a type has linkage. — *end note*]

[*Example*:

```
template <class T> struct B {
    void g(T) { }
    void h(T);
    friend void i(B, T) { }
};

void f() {
    struct A { int x; }; // no linkage
    A a = { 1 };
    B<A> ba;           // declares B<A>::g(A) and B<A>::h(A)
    ba.g(a);            // OK
    ba.h(a);            // error: B<A>::h(A) not defined in the translation unit
    i(ba, a);           // OK
}
```

— *end example*]

- 10 Two names that are the same (??) and that are declared in different scopes shall denote the same variable, function, type, template or namespace if

- (10.1) — both names have external linkage or else both names have internal linkage and are declared in the same translation unit; and

- (10.2) — both names refer to members of the same namespace or to members, not by inheritance, of the same class; and

- (10.3) — when both names denote functions, the parameter-type-lists of the functions (??) are identical; and

- (10.4) — when both names denote function templates, the signatures (??) are the same.

- 11 After all adjustments of types (during which typedefs (??) are replaced by their definitions), the types specified by all declarations referring to a given variable or function shall be identical, except that declarations for an array object can specify array types that differ by the presence or absence of a major array bound (??). A violation of this rule on type identity does not require a diagnostic.

- 12 [ *Note*: Linkage to non-C++ declarations can be achieved using a *linkage-specification* (??). — *end note*]

## 6.6 Memory and objects

[**basic.memobj**]

### 6.6.1 Memory model

[**intro.memory**]

- 1 The fundamental storage unit in the C++ memory model is the *byte*. A byte is at least large enough to contain any member of the basic execution character set (??) and the eight-bit code units of the Unicode UTF-8

encoding form and is composed of a contiguous sequence of bits,<sup>31</sup> the number of which is implementation-defined. The least significant bit is called the *low-order bit*; the most significant bit is called the *high-order bit*. The memory available to a C++ program consists of one or more sequences of contiguous bytes. Every byte has a unique address.

- <sup>2</sup> [ *Note:* The representation of types is described in ?? . — *end note* ]
- <sup>3</sup> A *memory location* is either an object of scalar type or a maximal sequence of adjacent bit-fields all having nonzero width. [ *Note:* Various features of the language, such as references and virtual functions, might involve additional memory locations that are not accessible to programs but are managed by the implementation. — *end note* ] Two or more threads of execution (??) can access separate memory locations without interfering with each other.
- <sup>4</sup> [ *Note:* Thus a bit-field and an adjacent non-bit-field are in separate memory locations, and therefore can be concurrently updated by two threads of execution without interference. The same applies to two bit-fields, if one is declared inside a nested struct declaration and the other is not, or if the two are separated by a zero-length bit-field declaration, or if they are separated by a non-bit-field declaration. It is not safe to concurrently update two bit-fields in the same struct if all fields between them are also bit-fields of nonzero width. — *end note* ]
- <sup>5</sup> [ *Example:* A structure declared as

```
struct {
    char a;
    int b:5,
        c:11,
        :0,
        d:8;
    struct {int ee:8;} e;
}
```

contains four separate memory locations: The member **a** and bit-fields **d** and **e.ee** are each separate memory locations, and can be modified concurrently without interfering with each other. The bit-fields **b** and **c** together constitute the fourth memory location. The bit-fields **b** and **c** cannot be concurrently modified, but **b** and **a**, for example, can be. — *end example* ]

## 6.6.2 Object model

[[intro.object](#)]

- <sup>1</sup> The constructs in a C++ program create, destroy, refer to, access, and manipulate objects. An *object* is created by a definition (??), by a *new-expression* (??), when implicitly changing the active member of a union (??), or when a temporary object is created (??, ??). An object occupies a region of storage in its period of construction (??), throughout its lifetime (??), and in its period of destruction (??). [ *Note:* A function is not an object, regardless of whether or not it occupies storage in the way that objects do. — *end note* ] The properties of an object are determined when the object is created. An object can have a name (??). An object has a storage duration (??) which influences its lifetime (??). An object has a type (??). Some objects are polymorphic (??); the implementation generates information associated with each such object that makes it possible to determine that object's type during program execution. For other objects, the interpretation of the values found therein is determined by the type of the *expressions* (??) used to access them.

---

<sup>31</sup>) The number of bits in a byte is reported by the macro `CHAR_BIT` in the header `<climits>`.

<sup>2</sup> Objects can contain other objects, called *subobjects*. A subobject can be a *member subobject* (??), a *base class subobject* (??), or an array element. An object that is not a subobject of any other object is called a *complete object*. If an object is created in storage associated with a member subobject or array element *e* (which may or may not be within its lifetime), the created object is a subobject of *e*'s containing object if:

- (2.1) — the lifetime of *e*'s containing object has begun and not ended, and
- (2.2) — the storage for the new object exactly overlays the storage location associated with *e*, and
- (2.3) — the new object is of the same type as *e* (ignoring cv-qualification).

[*Note*: If the subobject contains a reference member or a `const` subobject, the name of the original subobject cannot be used to access the new object (??). — *end note*] [*Example*:

```
struct X { const int n; };
union U { X x; float f; };
void tong() {
    U u = {{ 1 }};
    u.f = 5.f;                                // OK, creates new subobject of u (??)
    X *p = new (&u.x) X {2};                  // OK, creates new subobject of u
    assert(p->n == 2);                        // OK
    assert(*std::launder(&u.x.n) == 2);        // OK
    assert(u.x.n == 2);                        // undefined behavior, u.x does not name new subobject
}
— end example]
```

<sup>3</sup> If a complete object is created (??) in storage associated with another object *e* of type “array of *N unsigned char*” or of type “array of *N std::byte*” (??), that array *provides storage* for the created object if:

- (3.1) — the lifetime of *e* has begun and not ended, and
- (3.2) — the storage for the new object fits entirely within *e*, and
- (3.3) — there is no smaller array object that satisfies these constraints.

[*Note*: If that portion of the array previously provided storage for another object, the lifetime of that object ends because its storage was reused (??). — *end note*] [*Example*:

```
template<typename ...T>
struct AlignedUnion {
    alignas(T...) unsigned char data[max(sizeof(T)...)];
};

int f() {
    AlignedUnion<int, char> au;
    int *p = new (au.data) int;                // OK, au.data provides storage
    char *c = new (au.data) char();            // OK, ends lifetime of *p
    char *d = new (au.data + 1) char();
    return *c + *d; // OK
}

struct A { unsigned char a[32]; };
struct B { unsigned char b[16]; };
A a;
B *b = new (a.a + 8) B;                    // a.a provides storage for *b
int *p = new (b->b + 4) int;               // b->b provides storage for *p
```

// a.a does not provide storage for \*p (directly),  
 // but \*p is nested within a (see below)

— end example]

- 4 An object *a* is *nested within* another object *b* if:

- (4.1) — *a* is a subobject of *b*, or
- (4.2) — *b* provides storage for *a*, or
- (4.3) — there exists an object *c* where *a* is nested within *c*, and *c* is nested within *b*.

- 5 For every object *x*, there is some object called the *complete object of x*, determined as follows:

- (5.1) — If *x* is a complete object, then the complete object of *x* is itself.
- (5.2) — Otherwise, the complete object of *x* is the complete object of the (unique) object that contains *x*.

- 6 If a complete object, a data member (??), or an array element is of class type, its type is considered the *most derived class*, to distinguish it from the class type of any base class subobject; an object of a most derived class type or of a non-class type is called a *most derived object*.

- 7 Unless it is a bit-field (??), a most derived object shall have a nonzero size and shall occupy one or more bytes of storage. Base class subobjects may have zero size. An object of trivially copyable or standard-layout type (??) shall occupy contiguous bytes of storage.

- 8 Unless an object is a bit-field or a base class subobject of zero size, the address of that object is the address of the first byte it occupies. Two objects *a* and *b* with overlapping lifetimes that are not bit-fields may have the same address if one is nested within the other, or if at least one is a base class subobject of zero size and they are of different types; otherwise, they have distinct addresses.<sup>32</sup> [Example:

```
static const char test1 = 'x';
static const char test2 = 'x';
const bool b = &test1 != &test2;           // always true
```

— end example]

- 9 [Note: C++ provides a variety of fundamental types and several ways of composing new types from existing types (??). — end note]

### 6.6.3 Object lifetime

[basic.life]

- 1 The *lifetime* of an object or reference is a runtime property of the object or reference. An object is said to have *non-vacuous initialization* if it is of a class or aggregate type and it or one of its subobjects is initialized by a constructor other than a trivial default constructor. [Note: Initialization by a trivial copy/move constructor is non-vacuous initialization. — end note] The lifetime of an object of type *T* begins when:

- (1.1) — storage with the proper alignment and size for type *T* is obtained, and
- (1.2) — if the object has non-vacuous initialization, its initialization is complete,

except that if the object is a union member or subobject thereof, its lifetime only begins if that union member is the initialized member in the union (??, ??), or as described in ???. The lifetime of an object *o* of type *T* ends when:

- (1.3) — if *T* is a class type with a non-trivial destructor (??), the destructor call starts, or

<sup>32</sup> Under the “as-if” rule an implementation is allowed to store two objects at the same machine address or not store an object at all if the program cannot observe the difference (??).

- (1.4) — the storage which the object occupies is released, or is reused by an object that is not nested within *o* (??).
- 2 The lifetime of a reference begins when its initialization is complete. The lifetime of a reference ends as if it were a scalar object.
- 3 [ *Note*: ?? describes the lifetime of base and member subobjects. — *end note* ]
- 4 The properties ascribed to objects and references throughout this document apply for a given object or reference only during its lifetime. [ *Note*: In particular, before the lifetime of an object starts and after its lifetime ends there are significant restrictions on the use of the object, as described below, in ?? and in ?? . Also, the behavior of an object under construction and destruction might not be the same as the behavior of an object whose lifetime has started and not ended. ?? and ?? describe the behavior of objects during the construction and destruction phases. — *end note* ]
- 5 A program may end the lifetime of any object by reusing the storage which the object occupies or by explicitly calling the destructor for an object of a class type with a non-trivial destructor. For an object of a class type with a non-trivial destructor, the program is not required to call the destructor explicitly before the storage which the object occupies is reused or released; however, if there is no explicit call to the destructor or if a *delete-expression* (??) is not used to release the storage, the destructor shall not be implicitly called and any program that depends on the side effects produced by the destructor has undefined behavior.
- 6 Before the lifetime of an object has started but after the storage which the object will occupy has been allocated<sup>33</sup> or, after the lifetime of an object has ended and before the storage which the object occupied is reused or released, any pointer that represents the address of the storage location where the object will be or was located may be used but only in limited ways. For an object under construction or destruction, see ?? . Otherwise, such a pointer refers to allocated storage (??), and using the pointer as if the pointer were of type `void*`, is well-defined. Indirection through such a pointer is permitted but the resulting lvalue may only be used in limited ways, as described below. The program has undefined behavior if:
- (6.1) — the object will be or was of a class type with a non-trivial destructor and the pointer is used as the operand of a *delete-expression*,
  - (6.2) — the pointer is used to access a non-static data member or call a non-static member function of the object, or
  - (6.3) — the pointer is implicitly converted (??) to a pointer to a virtual base class, or
  - (6.4) — the pointer is used as the operand of a `static_cast` (??), except when the conversion is to pointer to *cv void*, or to pointer to *cv void* and subsequently to pointer to *cv char*, *cv unsigned char*, or *cv std::byte* (??), or
  - (6.5) — the pointer is used as the operand of a `dynamic_cast` (??).

[ *Example*:

```
#include <cstdlib>

struct B {
    virtual void f();
    void mutate();
    virtual ~B();
};
```

<sup>33</sup>) For example, before the construction of a global object that is initialized via a user-provided constructor (??).

```

struct D1 : B { void f(); };
struct D2 : B { void f(); };

void B::mutate() {
    new (this) D2;      // reuses storage — ends the lifetime of *this
    f();                // undefined behavior
    ... = this;          // OK, this points to valid memory
}

void g() {
    void* p = std::malloc(sizeof(D1) + sizeof(D2));
    B* pb = new (p) D1;
    pb->mutate();
    *pb;                 // OK: pb points to valid memory
    void* q = pb;         // OK: pb points to valid memory
    pb->f();             // undefined behavior, lifetime of *pb has ended
}

```

— end example]

- <sup>7</sup> Similarly, before the lifetime of an object has started but after the storage which the object will occupy has been allocated or, after the lifetime of an object has ended and before the storage which the object occupied is reused or released, any glvalue that refers to the original object may be used but only in limited ways. For an object under construction or destruction, see [??](#). Otherwise, such a glvalue refers to allocated storage ([??](#)), and using the properties of the glvalue that do not depend on its value is well-defined. The program has undefined behavior if:
  - (7.1) — the glvalue is used to access the object, or
  - (7.2) — the glvalue is used to call a non-static member function of the object, or
  - (7.3) — the glvalue is bound to a reference to a virtual base class ([??](#)), or
  - (7.4) — the glvalue is used as the operand of a `dynamic_cast` ([??](#)) or as the operand of `typeid`.
- <sup>8</sup> If, after the lifetime of an object has ended and before the storage which the object occupied is reused or released, a new object is created at the storage location which the original object occupied, a pointer that pointed to the original object, a reference that referred to the original object, or the name of the original object will automatically refer to the new object and, once the lifetime of the new object has started, can be used to manipulate the new object, if:
  - (8.1) — the storage for the new object exactly overlays the storage location which the original object occupied, and
  - (8.2) — the new object is of the same type as the original object (ignoring the top-level cv-qualifiers), and
  - (8.3) — the type of the original object is not const-qualified, and, if a class type, does not contain any non-static data member whose type is const-qualified or a reference type, and
  - (8.4) — the original object was a most derived object ([??](#)) of type T and the new object is a most derived object of type T (that is, they are not base class subobjects).

[Example:

```

struct C {
    int i;

```

```

void f();
const C& operator=( const C& );
};

const C& C::operator=( const C& other) {
    if ( this != &other ) {
        this->~C();                                // lifetime of *this ends
        new (this) C(other);                      // new object of type C created
        f();                                         // well-defined
    }
    return *this;
}

C c1;
C c2;
c1 = c2;                                       // well-defined
c1.f();                                         // well-defined; c1 refers to a new object of type C

```

— end example] [Note: If these conditions are not met, a pointer to the new object can be obtained from a pointer that represents the address of its storage by calling `std::launder(??)`. — end note]

- <sup>9</sup> If a program ends the lifetime of an object of type T with static (??), thread (??), or automatic (??) storage duration and if T has a non-trivial destructor,<sup>34</sup> the program must ensure that an object of the original type occupies that same storage location when the implicit destructor call takes place; otherwise the behavior of the program is undefined. This is true even if the block is exited with an exception. [Example:

```

class T { };
struct B {
    ~B();
};

void h() {
    B b;
    new (&b) T;
}
// undefined behavior at block exit

```

— end example]

- <sup>10</sup> Creating a new object within the storage that a const complete object with static, thread, or automatic storage duration occupies, or within the storage that such a const object used to occupy before its lifetime ended, results in undefined behavior. [Example:

```

struct B {
    B();
    ~B();
};

const B b;

```

---

<sup>34</sup>) That is, an object for which a destructor will be called implicitly—upon exit from the block for an object with automatic storage duration, upon exit from the thread for an object with thread storage duration, or upon exit from the program for an object with static storage duration.

```

void h() {
    b.~B();
    new (const_cast<B*>(&b)) const B;      // undefined behavior
}
— end example]

```

- <sup>11</sup> In this subclause, “before” and “after” refer to the “happens before” relation (??). [Note: Therefore, undefined behavior results if an object that is being constructed in one thread is referenced from another thread without adequate synchronization. — end note]

## 6.6.4 Storage duration

[basic.stc]

- <sup>1</sup> The *storage duration* is the property of an object that defines the minimum potential lifetime of the storage containing the object. The storage duration is determined by the construct used to create the object and is one of the following:
  - (1.1) — static storage duration
  - (1.2) — thread storage duration
  - (1.3) — automatic storage duration
  - (1.4) — dynamic storage duration
- <sup>2</sup> Static, thread, and automatic storage durations are associated with objects introduced by declarations (??) and implicitly created by the implementation (??). The dynamic storage duration is associated with objects created by a *new-expression* (??).
- <sup>3</sup> The storage duration categories apply to references as well.
- <sup>4</sup> When the end of the duration of a region of storage is reached, the values of all pointers representing the address of any part of that region of storage become invalid pointer values (??). Indirection through an invalid pointer value and passing an invalid pointer value to a deallocation function have undefined behavior. Any other use of an invalid pointer value has implementation-defined behavior.<sup>35</sup>

### 6.6.4.1 Static storage duration

[basic.stc.static]

- <sup>1</sup> All variables which do not have dynamic storage duration, do not have thread storage duration, and are not local have *static storage duration*. The storage for these entities shall last for the duration of the program (??, ??).
- <sup>2</sup> If a variable with static storage duration has initialization or a destructor with side effects, it shall not be eliminated even if it appears to be unused, except that a class object or its copy/move may be eliminated as specified in ??.
- <sup>3</sup> The keyword **static** can be used to declare a local variable with static storage duration. [Note: ?? describes the initialization of local **static** variables; ?? describes the destruction of local **static** variables. — end note]
- <sup>4</sup> The keyword **static** applied to a class data member in a class definition gives the data member static storage duration.

---

<sup>35</sup> Some implementations might define that copying an invalid pointer value causes a system-generated runtime fault.

**6.6.4.2 Thread storage duration**

[basic.stc.thread]

- <sup>1</sup> All variables declared with the `thread_local` keyword have *thread storage duration*. The storage for these entities shall last for the duration of the thread in which they are created. There is a distinct object or reference per thread, and use of the declared name refers to the entity associated with the current thread.
- <sup>2</sup> A variable with thread storage duration shall be initialized before its first odr-use (??) and, if constructed, shall be destroyed on thread exit.

**6.6.4.3 Automatic storage duration**

[basic.stc.auto]

- <sup>1</sup> Block-scope variables not explicitly declared `static`, `thread_local`, or `extern` have *automatic storage duration*. The storage for these entities lasts until the block in which they are created exits.
- <sup>2</sup> [Note: These variables are initialized and destroyed as described in ??.—end note]
- <sup>3</sup> If a variable with automatic storage duration has initialization or a destructor with side effects, an implementation shall not destroy it before the end of its block nor eliminate it as an optimization, even if it appears to be unused, except that a class object or its copy/move may be eliminated as specified in ??.

**6.6.4.4 Dynamic storage duration**

[basic.stc.dynamic]

- <sup>1</sup> Objects can be created dynamically during program execution (??), using *new-expressions* (??), and destroyed using *delete-expressions* (??). A C++ implementation provides access to, and management of, dynamic storage via the global *allocation functions operator new* and *operator new[]* and the global *deallocation functions operator delete* and *operator delete[]*. [Note: The non-allocating forms described in ?? do not perform allocation or deallocation. —end note]
- <sup>2</sup> The library provides default definitions for the global allocation and deallocation functions. Some global allocation and deallocation functions are replaceable (??). A C++ program shall provide at most one definition of a replaceable allocation or deallocation function. Any such function definition replaces the default version provided in the library (??). The following allocation and deallocation functions (??) are implicitly declared in global scope in each translation unit of a program.

```
[[nodiscard]] void* operator new(std::size_t);
[[nodiscard]] void* operator new(std::size_t, std::align_val_t);

void operator delete(void*) noexcept;
void operator delete(void*, std::size_t) noexcept;
void operator delete(void*, std::align_val_t) noexcept;
void operator delete(void*, std::size_t, std::align_val_t) noexcept;

[[nodiscard]] void* operator new[](std::size_t);
[[nodiscard]] void* operator new[](std::size_t, std::align_val_t);

void operator delete[](void*) noexcept;
void operator delete[](void*, std::size_t) noexcept;
void operator delete[](void*, std::align_val_t) noexcept;
void operator delete[](void*, std::size_t, std::align_val_t) noexcept;
```

These implicit declarations introduce only the function names `operator new`, `operator new[]`, `operator delete`, and `operator delete[]`. [Note: The implicit declarations do not introduce the names `std`, `std::size_t`, `std::align_val_t`, or any other names that the library uses to declare these names. Thus, a *new-expression*, *delete-expression* or function call that refers to one of these functions without including the

header <new> is well-formed. However, referring to `std` or `std::size_t` or `std::align_val_t` is ill-formed unless the name has been declared by including the appropriate header. — *end note*] Allocation and/or deallocation functions may also be declared and defined for any class (??).

- 3 Any allocation and/or deallocation functions defined in a C++ program, including the default versions in the library, shall conform to the semantics specified in ?? and ??.

#### 6.6.4.4.1 Allocation functions

[**basic.stc.dynamic.allocation**]

- <sup>1</sup> An allocation function shall be a class member function or a global function; a program is ill-formed if an allocation function is declared in a namespace scope other than global scope or declared static in global scope. The return type shall be `void*`. The first parameter shall have type `std::size_t` (??). The first parameter shall not have an associated default argument (??). The value of the first parameter shall be interpreted as the requested size of the allocation. An allocation function can be a function template. Such a template shall declare its return type and first parameter as specified above (that is, template parameter types shall not be used in the return type and first parameter type). Template allocation functions shall have two or more parameters.
- <sup>2</sup> The allocation function attempts to allocate the requested amount of storage. If it is successful, it shall return the address of the start of a block of storage whose length in bytes shall be at least as large as the requested size. There are no constraints on the contents of the allocated storage on return from the allocation function. The order, contiguity, and initial value of storage allocated by successive calls to an allocation function are unspecified. The pointer returned shall be suitably aligned so that it can be converted to a pointer to any suitable complete object type (??) and then used to access the object or array in the storage allocated (until the storage is explicitly deallocated by a call to a corresponding deallocation function). Even if the size of the space requested is zero, the request can fail. If the request succeeds, the value returned shall be a non-null pointer value (??) `p0` different from any previously returned value `p1`, unless that value `p1` was subsequently passed to an `operator delete`. Furthermore, for the library allocation functions in ?? and ??, `p0` shall represent the address of a block of storage disjoint from the storage for any other object accessible to the caller. The effect of indirecting through a pointer returned as a request for zero size is undefined.<sup>36</sup>
- <sup>3</sup> An allocation function that fails to allocate storage can invoke the currently installed new-handler function (??), if any. [*Note:* A program-supplied allocation function can obtain the address of the currently installed `new_handler` using the `std::get_new_handler` function (??). — *end note*] If an allocation function that has a non-throwing exception specification (??) fails to allocate storage, it shall return a null pointer. Any other allocation function that fails to allocate storage shall indicate failure only by throwing an exception (??) of a type that would match a handler (??) of type `std::bad_alloc` (??).
- <sup>4</sup> A global allocation function is only called as the result of a `new` expression (??), or called directly using the function call syntax (??), or called indirectly through calls to the functions in the C++ standard library. [*Note:* In particular, a global allocation function is not called to allocate storage for objects with static storage duration (??), for objects or references with thread storage duration (??), for objects of type `std::type_info` (??), or for an exception object (??). — *end note*]

#### 6.6.4.4.2 Deallocation functions

[**basic.stc.dynamic.deallocation**]

- Deallocation functions shall be class member functions or global functions; a program is ill-formed if deallocation functions are declared in a namespace scope other than global scope or declared static in global scope.

<sup>36</sup>) The intent is to have `operator new()` implementable by calling `std::malloc()` or `std::calloc()`, so the rules are substantially the same. C++ differs from C in requiring a zero request to return a non-null pointer.

<sup>2</sup> Each deallocation function shall return `void` and its first parameter shall be `void*`. A deallocation function may have more than one parameter. A *usual deallocation function* is a deallocation function that has:

- (2.1) — exactly one parameter; or
- (2.2) — exactly two parameters, the type of the second being either `std::align_val_t` or `std::size_t`<sup>37</sup>; or
- (2.3) — exactly three parameters, the type of the second being `std::size_t` and the type of the third being `std::align_val_t`.

A deallocation function may be an instance of a function template. Neither the first parameter nor the return type shall depend on a template parameter. [ *Note*: That is, a deallocation function template shall have a first parameter of type `void*` and a return type of `void` (as specified above). — *end note* ] A deallocation function template shall have two or more function parameters. A template instance is never a usual deallocation function, regardless of its signature.

- <sup>3</sup> If a deallocation function terminates by throwing an exception, the behavior is undefined. The value of the first argument supplied to a deallocation function may be a null pointer value; if so, and if the deallocation function is one supplied in the standard library, the call has no effect.
- <sup>4</sup> If the argument given to a deallocation function in the standard library is a pointer that is not the null pointer value (??), the deallocation function shall deallocate the storage referenced by the pointer, ending the duration of the region of storage.

#### 6.6.4.4.3 Safely-derived pointers

[**basic.stc.dynamic.safety**]

- <sup>1</sup> A *traceable pointer object* is
  - (1.1) — an object of an object pointer type (??), or
  - (1.2) — an object of an integral type that is at least as large as `std::intptr_t`, or
  - (1.3) — a sequence of elements in an array of narrow character type (??), where the size and alignment of the sequence match those of some object pointer type.
- <sup>2</sup> A pointer value is a *safely-derived pointer* to a dynamic object only if it has an object pointer type and it is one of the following:
  - (2.1) — the value returned by a call to the C++ standard library implementation of `::operator new(std::size_t)` or `::operator new(std::size_t, std::align_val_t)`,<sup>38</sup>
  - (2.2) — the result of taking the address of an object (or one of its subobjects) designated by an lvalue resulting from indirection through a safely-derived pointer value;
  - (2.3) — the result of well-defined pointer arithmetic (??) using a safely-derived pointer value;
  - (2.4) — the result of a well-defined pointer conversion (??, ??) of a safely-derived pointer value;
  - (2.5) — the result of a `reinterpret_cast` of a safely-derived pointer value;
  - (2.6) — the result of a `reinterpret_cast` of an integer representation of a safely-derived pointer value;
  - (2.7) — the value of an object whose value was copied from a traceable pointer object, where at the time of the copy the source object contained a copy of a safely-derived pointer value.

<sup>37</sup>) The global `operator delete(void*, std::size_t)` precludes use of an allocation function `void operator new(std::size_t, std::size_t)` as a placement allocation function (??).

<sup>38</sup>) This subclause does not impose restrictions on indirection through pointers to memory not allocated by `::operator new`. This maintains the ability of many C++ implementations to use binary libraries and components written in other languages. In particular, this applies to C binaries, because indirection through pointers to memory allocated by `std::malloc` is not restricted.

- <sup>3</sup> An integer value is an *integer representation of a safely-derived pointer* only if its type is at least as large as `std::intptr_t` and it is one of the following:
- (3.1) — the result of a `reinterpret_cast` of a safely-derived pointer value;
  - (3.2) — the result of a valid conversion of an integer representation of a safely-derived pointer value;
  - (3.3) — the value of an object whose value was copied from a traceable pointer object, where at the time of the copy the source object contained an integer representation of a safely-derived pointer value;
  - (3.4) — the result of an additive or bitwise operation, one of whose operands is an integer representation of a safely-derived pointer value  $P$ , if that result converted by `reinterpret_cast<void*>` would compare equal to a safely-derived pointer computable from `reinterpret_cast<void*>(P)`.
- <sup>4</sup> An implementation may have *relaxed pointer safety*, in which case the validity of a pointer value does not depend on whether it is a safely-derived pointer value. Alternatively, an implementation may have *strict pointer safety*, in which case a pointer value referring to an object with dynamic storage duration that is not a safely-derived pointer value is an invalid pointer value unless the referenced complete object has previously been declared reachable (??). [ *Note*: The effect of using an invalid pointer value (including passing it to a deallocation function) is undefined, see ?? . This is true even if the unsafely-derived pointer value might compare equal to some safely-derived pointer value. — *end note* ] It is implementation-defined whether an implementation has relaxed or strict pointer safety.

#### 6.6.4.5 Duration of subobjects

[**basic.stc.inherit**]

- <sup>1</sup> The storage duration of subobjects and reference members is that of their complete object (??).

#### 6.6.5 Alignment

[**basic.align**]

- <sup>1</sup> Object types have *alignment requirements* (??, ??) which place restrictions on the addresses at which an object of that type may be allocated. An *alignment* is an implementation-defined integer value representing the number of bytes between successive addresses at which a given object can be allocated. An object type imposes an alignment requirement on every object of that type; stricter alignment can be requested using the alignment specifier (??).
- <sup>2</sup> A *fundamental alignment* is represented by an alignment less than or equal to the greatest alignment supported by the implementation in all contexts, which is equal to `alignof(std::max_align_t)` (??). The alignment required for a type might be different when it is used as the type of a complete object and when it is used as the type of a subobject. [ *Example*:

```
struct B { long double d; };
struct D : virtual B { char c; };
```

When `D` is the type of a complete object, it will have a subobject of type `B`, so it must be aligned appropriately for a `long double`. If `D` appears as a subobject of another object that also has `B` as a virtual base class, the `B` subobject might be part of a different subobject, reducing the alignment requirements on the `D` subobject. — *end example* ] The result of the `alignof` operator reflects the alignment requirement of the type in the complete-object case.

- <sup>3</sup> An *extended alignment* is represented by an alignment greater than `alignof(std::max_align_t)`. It is implementation-defined whether any extended alignments are supported and the contexts in which they are supported (??). A type having an extended alignment requirement is an *over-aligned type*. [ *Note*: Every over-aligned type is or contains a class type to which extended alignment applies (possibly through a non-static data member). — *end note* ] A *new-extended alignment* is represented by an alignment greater than `__STDCPP_DEFAULT_NEW_ALIGNMENT__` (??).

- <sup>4</sup> Alignments are represented as values of the type `std::size_t`. Valid alignments include only those values returned by an `alignof` expression for the fundamental types plus an additional implementation-defined set of values, which may be empty. Every alignment value shall be a non-negative integral power of two.
- <sup>5</sup> Alignments have an order from *weaker* to *stronger* or *stricter* alignments. Stricter alignments have larger alignment values. An address that satisfies an alignment requirement also satisfies any weaker valid alignment requirement.
- <sup>6</sup> The alignment requirement of a complete type can be queried using an `alignof` expression (??). Furthermore, the narrow character types (??) shall have the weakest alignment requirement. [ *Note:* This enables the narrow character types to be used as the underlying type for an aligned memory area (??). — *end note* ]
- <sup>7</sup> Comparing alignments is meaningful and provides the obvious results:
  - (7.1) — Two alignments are equal when their numeric values are equal.
  - (7.2) — Two alignments are different when their numeric values are not equal.
  - (7.3) — When an alignment is larger than another it represents a stricter alignment.
- <sup>8</sup> [ *Note:* The runtime pointer alignment function (??) can be used to obtain an aligned pointer within a buffer; the aligned-storage templates in the library (??) can be used to obtain aligned storage. — *end note* ]
- <sup>9</sup> If a request for a specific extended alignment in a specific context is not supported by an implementation, the program is ill-formed.

## 6.7 Types

[**basic.types**]

- <sup>1</sup> [ *Note:* ?? and the subclauses thereof impose requirements on implementations regarding the representation of types. There are two kinds of types: fundamental types and compound types. Types describe objects (??), references (??), or functions (??). — *end note* ]
- <sup>2</sup> For any object (other than a base-class subobject) of trivially copyable type T, whether or not the object holds a valid value of type T, the underlying bytes (??) making up the object can be copied into an array of `char`, `unsigned char`, or `std::byte` (??).<sup>39</sup> If the content of that array is copied back into the object, the object shall subsequently hold its original value. [ *Example:* ]

```
#define N sizeof(T)
char buf[N];
T obj;                                // obj initialized to its original value
std::memcpy(buf, &obj, N);              // between these two calls to std::memcpy, obj might be modified
std::memcpy(&obj, buf, N);              // at this point, each subobject of obj of scalar type holds its original value
— end example ]
```

- <sup>3</sup> For any trivially copyable type T, if two pointers to T point to distinct T objects `obj1` and `obj2`, where neither `obj1` nor `obj2` is a base-class subobject, if the underlying bytes (??) making up `obj1` are copied into `obj2`,<sup>40</sup> `obj2` shall subsequently hold the same value as `obj1`. [ *Example:* ]

```
T* t1p;
T* t2p;
// provided that t2p points to an initialized object ...
std::memcpy(t1p, t2p, sizeof(T));
// at this point, every subobject of trivially copyable type in *t1p contains
// the same value as the corresponding subobject in *t2p
```

<sup>39</sup>) By using, for example, the library functions (??) `std::memcpy` or `std::memmove`.

<sup>40</sup>) By using, for example, the library functions (??) `std::memcpy` or `std::memmove`.

— end example]

- <sup>4</sup> The *object representation* of an object of type T is the sequence of N `unsigned char` objects taken up by the object of type T, where N equals `sizeof(T)`. The *value representation* of an object is the set of bits that hold the value of type T. Bits in the object representation that are not part of the value representation are *padding bits*. For trivially copyable types, the value representation is a set of bits in the object representation that determines a *value*, which is one discrete element of an implementation-defined set of values.<sup>41</sup>
- <sup>5</sup> A class that has been declared but not defined, an enumeration type in certain contexts (??), or an array of unknown bound or of incomplete element type, is an *incompletely-defined object type*.<sup>42</sup> Incompletely-defined object types and cv `void` are *incomplete types* (??). Objects shall not be defined to have an incomplete type.
- <sup>6</sup> A class type (such as “`class X`”) might be incomplete at one point in a translation unit and complete later on; the type “`class X`” is the same type at both points. The declared type of an array object might be an array of incomplete class type and therefore incomplete; if the class type is completed later on in the translation unit, the array type becomes complete; the array type at those two points is the same type. The declared type of an array object might be an array of unknown bound and therefore be incomplete at one point in a translation unit and complete later on; the array types at those two points (“array of unknown bound of T” and “array of N T”) are different types. The type of a pointer to array of unknown bound, or of a type defined by a `typedef` declaration to be an array of unknown bound, cannot be completed. [Example:

```

class X;                                // X is an incomplete type
extern X* xp;                            // xp is a pointer to an incomplete type
extern int arr[];                         // the type of arr is incomplete
typedef int UNKA[];                      // UNKA is an incomplete type
UNKA* arrp;                             // arrp is a pointer to an incomplete type
UNKA** arrpp;

void foo() {
    xp++;                                // ill-formed: X is incomplete
    arrp++;                               // ill-formed: incomplete type
    arrpp++;                             // OK: sizeof UNKA* is known
}

struct X { int i; };                     // now X is a complete type
int arr[10];                            // now the type of arr is complete

X x;
void bar() {
    xp = &x;                           // OK; type is “pointer to X”
    arrp = &arr;                      // ill-formed: different types
    xp++;                            // OK: X is complete
    arrp++;                           // ill-formed: UNKA can't be completed
}

```

— end example]

- <sup>7</sup> [Note: The rules for declarations and expressions describe in which contexts incomplete types are prohibited.  
— end note]

---

<sup>41</sup>) The intent is that the memory model of C++ is compatible with that of ISO/IEC 9899 Programming Language C.

<sup>42</sup>) The size and layout of an instance of an incompletely-defined object type is unknown.

- <sup>8</sup> An *object type* is a (possibly cv-qualified) type that is not a function type, not a reference type, and not *cv void*.
- <sup>9</sup> Arithmetic types (??), enumeration types, pointer types, pointer-to-member types (??), `std::nullptr_t`, and cv-qualified (??) versions of these types are collectively called *scalar types*. Cv-unqualified scalar types, trivially copyable class types (??), arrays of such types, and cv-qualified versions of these types are collectively called *trivially copyable types*. Scalar types, trivial class types (??), arrays of such types and cv-qualified versions of these types are collectively called *trivial types*. Scalar types, standard-layout class types (??), arrays of such types and cv-qualified versions of these types are collectively called *standard-layout types*.
- <sup>10</sup> A type is a *literal type* if it is:
  - (10.1) — possibly cv-qualified `void`; or
  - (10.2) — a scalar type; or
  - (10.3) — a reference type; or
  - (10.4) — an array of literal type; or
  - (10.5) — a possibly cv-qualified class type (??) that has all of the following properties:
    - (10.5.1) — it has a trivial destructor,
    - (10.5.2) — it is either a closure type (??), an aggregate type (??), or has at least one `constexpr` constructor or constructor template (possibly inherited (??) from a base class) that is not a copy or move constructor,
    - (10.5.3) — if it is a union, at least one of its non-static data members is of non-volatile literal type, and
    - (10.5.4) — if it is not a union, all of its non-static data members and base classes are of non-volatile literal types.

[*Note*: A literal type is one for which it might be possible to create an object within a constant expression. It is not a guarantee that it is possible to create such an object, nor is it a guarantee that any object of that type will be usable in a constant expression. — *end note*]

- <sup>11</sup> Two types *cv1 T1* and *cv2 T2* are *layout-compatible* types if *T1* and *T2* are the same type, layout-compatible enumerations (??), or layout-compatible standard-layout class types (??).

### 6.7.1 Fundamental types

[**basic.fundamental**]

- <sup>1</sup> Objects declared as characters (`char`) shall be large enough to store any member of the implementation's basic character set. If a character from this set is stored in a character object, the integral value of that character object is equal to the value of the single character literal form of that character. It is implementation-defined whether a `char` object can hold negative values. Characters can be explicitly declared `unsigned` or `signed`. Plain `char`, `signed char`, and `unsigned char` are three distinct types, collectively called *narrow character types*. A `char`, a `signed char`, and an `unsigned char` occupy the same amount of storage and have the same alignment requirements (??); that is, they have the same object representation. For narrow character types, all bits of the object representation participate in the value representation. [ *Note*: A bit-field of narrow character type whose length is larger than the number of bits in the object representation of that type has padding bits; see ??-. — *end note*] For unsigned narrow character types, each possible bit pattern of the value representation represents a distinct number. These requirements do not hold for other types. In any particular implementation, a plain `char` object can take on either the same values as a `signed char` or an `unsigned char`; which one is implementation-defined. For each value *i* of type `unsigned char` in the range

0 to 255 inclusive, there exists a value  $j$  of type `char` such that the result of an integral conversion (??) from  $i$  to `char` is  $j$ , and the result of an integral conversion from  $j$  to `unsigned char` is  $i$ .

- 2 There are five *standard signed integer types*: “`signed char`”, “`short int`”, “`int`”, “`long int`”, and “`long long int`”. In this list, each type provides at least as much storage as those preceding it in the list. There may also be implementation-defined *extended signed integer types*. The standard and extended signed integer types are collectively called *signed integer types*. Plain `ints` have the natural size suggested by the architecture of the execution environment<sup>43</sup>; the other signed integer types are provided to meet special needs.
- 3 For each of the standard signed integer types, there exists a corresponding (but different) *standard unsigned integer type*: “`unsigned char`”, “`unsigned short int`”, “`unsigned int`”, “`unsigned long int`”, and “`unsigned long long int`”, each of which occupies the same amount of storage and has the same alignment requirements (??) as the corresponding signed integer type<sup>44</sup>; that is, each signed integer type has the same object representation as its corresponding unsigned integer type. Likewise, for each of the extended signed integer types there exists a corresponding *extended unsigned integer type* with the same amount of storage and alignment requirements. The standard and extended unsigned integer types are collectively called *unsigned integer types*. The range of non-negative values of a signed integer type is a subrange of the corresponding unsigned integer type, the representation of the same value in each of the two types is the same, and the value representation of each corresponding signed/unsigned type shall be the same. The standard signed integer types and standard unsigned integer types are collectively called the *standard integer types*, and the extended signed integer types and extended unsigned integer types are collectively called the *extended integer types*. The signed and unsigned integer types shall satisfy the constraints given in the C standard, subclause 5.2.4.2.1.
- 4 Unsigned integers shall obey the laws of arithmetic modulo  $2^n$  where  $n$  is the number of bits in the value representation of that particular size of integer.<sup>45</sup>
- 5 Type `wchar_t` is a distinct type whose values can represent distinct codes for all members of the largest extended character set specified among the supported locales (??). Type `wchar_t` shall have the same size, signedness, and alignment requirements (??) as one of the other integral types, called its *underlying type*. Types `char16_t` and `char32_t` denote distinct types with the same size, signedness, and alignment as `uint_least16_t` and `uint_least32_t`, respectively, in `<cstdint>`, called the underlying types.
- 6 Values of type `bool` are either `true` or `false`.<sup>46</sup> [Note: There are no `signed`, `unsigned`, `short`, or `long bool` types or values. — end note] Values of type `bool` participate in integral promotions (??).
- 7 Types `bool`, `char`, `char16_t`, `char32_t`, `wchar_t`, and the signed and unsigned integer types are collectively called *integral types*.<sup>47</sup> A synonym for integral type is *integer type*. The representations of integral types shall define values by use of a pure binary numeration system.<sup>48</sup> [Example: This document permits two’s complement, ones’ complement and signed magnitude representations for integral types. — end example]
- 8 There are three *floating-point types*: `float`, `double`, and `long double`. The type `double` provides at least as much precision as `float`, and the type `long double` provides at least as much precision as `double`. The set of

<sup>43</sup>) `int` must also be large enough to contain any value in the range [`INT_MIN`, `INT_MAX`], as defined in the header `<climits>`.

<sup>44</sup>) See ?? regarding the correspondence between types and the sequences of *type-specifiers* that designate them.

<sup>45</sup>) This implies that unsigned arithmetic does not overflow because a result that cannot be represented by the resulting unsigned integer type is reduced modulo the number that is one greater than the largest value that can be represented by the resulting unsigned integer type.

<sup>46</sup>) Using a `bool` value in ways described by this document as “undefined”, such as by examining the value of an uninitialized automatic object, might cause it to behave as if it is neither `true` nor `false`.

<sup>47</sup>) Therefore, enumerations (??) are not integral; however, enumerations can be promoted to integral types as specified in ??.

<sup>48</sup>) A positional representation for integers that uses the binary digits 0 and 1, in which the values represented by successive bits are additive, begin with 1, and are multiplied by successive integral power of 2, except perhaps for the bit with the highest position. (Adapted from the *American National Dictionary for Information Processing Systems*.)

values of the type `float` is a subset of the set of values of the type `double`; the set of values of the type `double` is a subset of the set of values of the type `long double`. The value representation of floating-point types is implementation-defined. [ *Note:* This document imposes no requirements on the accuracy of floating-point operations; see also ?? . — *end note* ] Integral and floating types are collectively called *arithmetic types*. Specializations of the standard library template `std::numeric_limits` (??) shall specify the maximum and minimum values of each arithmetic type for an implementation.

- <sup>9</sup> A type *cv void* is an incomplete type that cannot be completed; such a type has an empty set of values. It is used as the return type for functions that do not return a value. Any expression can be explicitly converted to type *cv void* (??). An expression of type *cv void* shall be used only as an expression statement (??), as an operand of a comma expression (??), as a second or third operand of ?: (??), as the operand of `typeid`, `noexcept`, or `decltype`, as the expression in a return statement (??) for a function with the return type *cv void*, or as the operand of an explicit conversion to type *cv void*.
- <sup>10</sup> A value of type `std::nullptr_t` is a null pointer constant (??). Such values participate in the pointer and the pointer-to-member conversions (??, ??). `sizeof(std::nullptr_t)` shall be equal to `sizeof(void*)`.
- <sup>11</sup> [ *Note:* Even if the implementation defines two or more basic types to have the same value representation, they are nevertheless different types. — *end note* ]

## 6.7.2 Compound types

[**basic.compound**]

- <sup>1</sup> Compound types can be constructed in the following ways:
  - (1.1) — arrays of objects of a given type, ??;
  - (1.2) — functions, which have parameters of given types and return `void` or references or objects of a given type, ??;
  - (1.3) — pointers to *cv void* or objects or functions (including static members of classes) of a given type, ??;
  - (1.4) — references to objects or functions of a given type, ?? . There are two types of references:
    - (1.4.1) — lvalue reference
    - (1.4.2) — rvalue reference
  - (1.5) — classes containing a sequence of objects of various types (??), a set of types, enumerations and functions for manipulating these objects (??), and a set of restrictions on the access to these entities (??);
  - (1.6) — unions, which are classes capable of containing objects of different types at different times, ??;
  - (1.7) — enumerations, which comprise a set of named constant values. Each distinct enumeration constitutes a different *enumerated type*, ??;
  - (1.8) — pointers to non-static class members,<sup>49</sup> which identify members of a given type within objects of a given class, ?? . Pointers to data members and pointers to member functions are collectively called *pointer-to-member* types.
- <sup>2</sup> These methods of constructing types can be applied recursively; restrictions are mentioned in ??, ??, ??, and ?? . Constructing a type such that the number of bytes in its object representation exceeds the maximum value representable in the type `std::size_t` (??) is ill-formed.
- <sup>3</sup> The type of a pointer to *cv void* or a pointer to an object type is called an *object pointer type*. [ *Note:* A pointer to `void` does not have a pointer-to-object type, however, because `void` is not an object type. — *end note* ] The type of a pointer that can designate a function is called a *function pointer type*. A pointer to

<sup>49</sup>) Static class members are objects or functions, and pointers to them are ordinary pointers to objects or functions.

objects of type T is referred to as a “pointer to T”. [Example: A pointer to an object of type `int` is referred to as “pointer to `int`” and a pointer to an object of class X is called a “pointer to X”. —end example] Except for pointers to static members, text referring to “pointers” does not apply to pointers to members. Pointers to incomplete types are allowed although there are restrictions on what can be done with them (??). Every value of pointer type is one of the following:

- (3.1) — a *pointer to* an object or function (the pointer is said to *point to* the object or function), or
- (3.2) — a *pointer past the end of* an object (??), or
- (3.3) — the *null pointer value* (??) for that type, or
- (3.4) — an *invalid pointer value*.

A value of a pointer type that is a pointer to or past the end of an object *represents the address* of the first byte in memory (??) occupied by the object<sup>50</sup> or the first byte in memory after the end of the storage occupied by the object, respectively. [Note: A pointer past the end of an object (??) is not considered to point to an unrelated object of the object’s type that might be located at that address. A pointer value becomes invalid when the storage it denotes reaches the end of its storage duration; see ??.. —end note] For purposes of pointer arithmetic (??) and comparison (??, ??), a pointer past the end of the last element of an array x of n elements is considered to be equivalent to a pointer to a hypothetical element x[n]. The value representation of pointer types is implementation-defined. Pointers to layout-compatible types shall have the same value representation and alignment requirements (??). [Note: Pointers to over-aligned types (??) have no special representation, but their range of valid values is restricted by the extended alignment requirement. —end note]

<sup>4</sup> Two objects a and b are *pointer-interconvertible* if:

- (4.1) — they are the same object, or
- (4.2) — one is a union object and the other is a non-static data member of that object (??), or
- (4.3) — one is a standard-layout class object and the other is the first non-static data member of that object, or, if the object has no non-static data members, the first base class subobject of that object (??), or
- (4.4) — there exists an object c such that a and c are pointer-interconvertible, and c and b are pointer-interconvertible.

If two objects are pointer-interconvertible, then they have the same address, and it is possible to obtain a pointer to one from a pointer to the other via a `reinterpret_cast` (??). [Note: An array object and its first element are not pointer-interconvertible, even though they have the same address. —end note]

<sup>5</sup> A pointer to cv-qualified (??) or cv-unqualified `void` can be used to point to objects of unknown type. Such a pointer shall be able to hold any object pointer. An object of type cv `void*` shall have the same representation and alignment requirements as cv `char*`.

### 6.7.3 CV-qualifiers

[**basic.type.qualifier**]

<sup>1</sup> A type mentioned in ?? and ?? is a *cv-unqualified type*. Each type which is a cv-unqualified complete or incomplete object type or is `void` (??) has three corresponding cv-qualified versions of its type: a *const-qualified* version, a *volatile-qualified* version, and a *const-volatile-qualified* version. The type of an object (??) includes the *cv-qualifiers* specified in the *decl-specifier-seq* (??), *declarator* (??), *type-id* (??), or *new-type-id* (??) when the object is created.

- (1.1) — A *const object* is an object of type `const T` or a non-mutable subobject of such an object.

---

<sup>50</sup> For an object that is not within its lifetime, this is the first byte in memory that it will occupy or used to occupy.

- (1.2) — A *volatile object* is an object of type `volatile T`, a subobject of such an object, or a mutable subobject of a `const volatile` object.
- (1.3) — A *const volatile object* is an object of type `const volatile T`, a non-mutable subobject of such an object, a `const` subobject of a *volatile object*, or a non-mutable *volatile subobject* of a `const` object.

The cv-qualified or cv-unqualified versions of a type are distinct types; however, they shall have the same representation and alignment requirements (??).<sup>51</sup>

- <sup>2</sup> A compound type (??) is not cv-qualified by the cv-qualifiers (if any) of the types from which it is compounded. Any cv-qualifiers applied to an array type affect the array element type (??).
- <sup>3</sup> See ?? and ?? regarding function types that have *cv-qualifiers*.
- <sup>4</sup> There is a partial ordering on cv-qualifiers, so that a type can be said to be *more cv-qualified* than another. Table ?? shows the relations that constitute this ordering.

Table 10 — Relations on `const` and `volatile`

<i>no cv-qualifier</i>	<	<code>const</code>
<i>no cv-qualifier</i>	<	<code>volatile</code>
<i>no cv-qualifier</i>	<	<code>const volatile</code>
<code>const</code>	<	<code>const volatile</code>
<code>volatile</code>	<	<code>const volatile</code>

- <sup>5</sup> In this document, the notation *cv* (or *cv1*, *cv2*, etc.), used in the description of types, represents an arbitrary set of cv-qualifiers, i.e., one of {`const`}, {`volatile`}, {`const, volatile`}, or the empty set. For a type *cv T*, the *top-level cv-qualifiers* of that type are those denoted by *cv*. [Example: The type corresponding to the *type-id const int&* has no top-level cv-qualifiers. The type corresponding to the *type-id volatile int \* const* has the top-level cv-qualifier `const`. For a class type *C*, the type corresponding to the *type-id void (C::\*: volatile)(int) const* has the top-level cv-qualifier `volatile`. — end example]
- <sup>6</sup> Cv-qualifiers applied to an array type attach to the underlying element type, so the notation “*cv T*”, where *T* is an array type, refers to an array whose elements are so-qualified. An array type whose elements are cv-qualified is also considered to have the same cv-qualifications as its elements. [Example:

```
typedef char CA[5];
typedef const char CC;
CC arr1[5] = { 0 };
const CA arr2 = { 0 };
```

The type of both `arr1` and `arr2` is “array of 5 `const char`”, and the array type is considered to be `const`-qualified. — end example]

#### 6.7.4 Integer conversion rank

[conv.rank]

- <sup>1</sup> Every integer type has an *integer conversion rank* defined as follows:
  - (1.1) — No two signed integer types other than `char` and `signed char` (if `char` is signed) shall have the same rank, even if they have the same representation.
  - (1.2) — The rank of a signed integer type shall be greater than the rank of any signed integer type with a smaller size.

<sup>51</sup>) The same representation and alignment requirements are meant to imply interchangeability as arguments to functions, return values from functions, and non-static data members of unions.

- (1.3) — The rank of `long long int` shall be greater than the rank of `long int`, which shall be greater than the rank of `int`, which shall be greater than the rank of `short int`, which shall be greater than the rank of `signed char`.
- (1.4) — The rank of any unsigned integer type shall equal the rank of the corresponding signed integer type.
- (1.5) — The rank of any standard integer type shall be greater than the rank of any extended integer type with the same size.
- (1.6) — The rank of `char` shall equal the rank of `signed char` and `unsigned char`.
- (1.7) — The rank of `bool` shall be less than the rank of all other standard integer types.
- (1.8) — The ranks of `char16_t`, `char32_t`, and `wchar_t` shall equal the ranks of their underlying types (??).
- (1.9) — The rank of any extended signed integer type relative to another extended signed integer type with the same size is implementation-defined, but still subject to the other rules for determining the integer conversion rank.
- (1.10) — For all integer types `T1`, `T2`, and `T3`, if `T1` has greater rank than `T2` and `T2` has greater rank than `T3`, then `T1` shall have greater rank than `T3`.

[*Note*: The integer conversion rank is used in the definition of the integral promotions (??) and the usual arithmetic conversions (??). — *end note*]

## 6.8 Program execution

[**basic.exec**]

### 6.8.1 Sequential execution

[**intro.execution**]

<sup>1</sup> An instance of each object with automatic storage duration (??) is associated with each entry into its block. Such an object exists and retains its last-stored value during the execution of the block and while the block is suspended (by a call of a function or receipt of a signal).

<sup>2</sup> A *constituent expression* is defined as follows:

- (2.1) — The constituent expression of an expression is that expression.
- (2.2) — The constituent expressions of a *braced-init-list* or of a (possibly parenthesized) *expression-list* are the constituent expressions of the elements of the respective list.
- (2.3) — The constituent expressions of a *brace-or-equal-initializer* of the form `= initializer-clause` are the constituent expressions of the *initializer-clause*.

[*Example*:

```
struct A { int x; };
struct B { int y; struct A a; };
B b = { 5, { 1+1 } };
```

The constituent expressions of the *initializer* used for the initialization of `b` are `5` and `1+1`. — *end example*]

<sup>3</sup> The *immediate subexpressions* of an expression `e` are

- (3.1) — the constituent expressions of `e`'s operands (??),
- (3.2) — any function call that `e` implicitly invokes,
- (3.3) — if `e` is a *lambda-expression* (??), the initialization of the entities captured by copy and the constituent expressions of the *initializer* of the *init-captures*,
- (3.4) — if `e` is a function call (??) or implicitly invokes a function, the constituent expressions of each default argument (??) used in the call, or

- (3.5) — if  $\mathbf{e}$  creates an aggregate object (??), the constituent expressions of each default member initializer (??) used in the initialization.
- <sup>4</sup> A *subexpression* of an expression  $\mathbf{e}$  is an immediate subexpression of  $\mathbf{e}$  or a subexpression of an immediate subexpression of  $\mathbf{e}$ . [Note: Expressions appearing in the *compound-statement* of a *lambda-expression* are not subexpressions of the *lambda-expression*. — end note]
- <sup>5</sup> A *full-expression* is
- (5.1) — an unevaluated operand (??),
  - (5.2) — a *constant-expression* (??),
  - (5.3) — an *init-declarator* (??) or a *mem-initializer* (??), including the constituent expressions of the initializer,
  - (5.4) — an invocation of a destructor generated at the end of the lifetime of an object other than a temporary object (??), or
  - (5.5) — an expression that is not a subexpression of another expression and that is not otherwise part of a full-expression.

If a language construct is defined to produce an implicit call of a function, a use of the language construct is considered to be an expression for the purposes of this definition. Conversions applied to the result of an expression in order to satisfy the requirements of the language construct in which the expression appears are also considered to be part of the full-expression. For an initializer, performing the initialization of the entity (including evaluating default member initializers of an aggregate) is also considered part of the full-expression.

[Example:

```

struct S {
    S(int i): I(i) { }           // full-expression is initialization of I
    int& v() { return I; }
    ~S() noexcept(false) { }

private:
    int I;
};

S s1(1);                      // full-expression comprises call of S::S(int)
void f() {
    S s2 = 2;                  // full-expression comprises call of S::S(int)
    if (S(3).v())              // full-expression includes lvalue-to-rvalue and int to bool conversions,
        // performed before temporary is deleted at end of full-expression
    {}
    bool b = noexcept(S());     // exception specification of destructor of S considered for noexcept

    // full-expression is destruction of s2 at end of block
}
struct B {
    B(S = S(0));
};
B b[2] = { B(), B() };          // full-expression is the entire initialization
                                // including the destruction of temporaries

— end example]

```

- <sup>6</sup> [ *Note*: The evaluation of a full-expression can include the evaluation of subexpressions that are not lexically part of the full-expression. For example, subexpressions involved in evaluating default arguments (??) are considered to be created in the expression that calls the function, not the expression that defines the default argument. — *end note* ]
- <sup>7</sup> Reading an object designated by a **volatile** glvalue (??), modifying an object, calling a library I/O function, or calling a function that does any of those operations are all *side effects*, which are changes in the state of the execution environment. *Evaluation* of an expression (or a subexpression) in general includes both value computations (including determining the identity of an object for glvalue evaluation and fetching a value previously assigned to an object for prvalue evaluation) and initiation of side effects. When a call to a library I/O function returns or an access through a volatile glvalue is evaluated the side effect is considered complete, even though some external actions implied by the call (such as the I/O itself) or by the **volatile** access may not have completed yet.
- <sup>8</sup> *Sequenced before* is an asymmetric, transitive, pair-wise relation between evaluations executed by a single thread (??), which induces a partial order among those evaluations. Given any two evaluations *A* and *B*, if *A* is sequenced before *B* (or, equivalently, *B* is *sequenced after* *A*), then the execution of *A* shall precede the execution of *B*. If *A* is not sequenced before *B* and *B* is not sequenced before *A*, then *A* and *B* are *unsequenced*. [ *Note*: The execution of unsequenced evaluations can overlap. — *end note* ] Evaluations *A* and *B* are *indeterminately sequenced* when either *A* is sequenced before *B* or *B* is sequenced before *A*, but it is unspecified which. [ *Note*: Indeterminately sequenced evaluations cannot overlap, but either could be executed first. — *end note* ] An expression *X* is said to be sequenced before an expression *Y* if every value computation and every side effect associated with the expression *X* is sequenced before every value computation and every side effect associated with the expression *Y*.
- <sup>9</sup> Every value computation and side effect associated with a full-expression is sequenced before every value computation and side effect associated with the next full-expression to be evaluated.<sup>52</sup>
- <sup>10</sup> Except where noted, evaluations of operands of individual operators and of subexpressions of individual expressions are unsequenced. [ *Note*: In an expression that is evaluated more than once during the execution of a program, unsequenced and indeterminately sequenced evaluations of its subexpressions need not be performed consistently in different evaluations. — *end note* ] The value computations of the operands of an operator are sequenced before the value computation of the result of the operator. If a side effect on a memory location (??) is unsequenced relative to either another side effect on the same memory location or a value computation using the value of any object in the same memory location, and they are not potentially concurrent (??), the behavior is undefined. [ *Note*: The next subclause imposes similar, but more complex restrictions on potentially concurrent computations. — *end note* ]

[ *Example*:

```
void g(int i) {
    i = 7, i++, i++; // i becomes 9

    i = i++ + 1; // the value of i is incremented
    i = i++ + i; // the behavior is undefined
    i = i + 1; // the value of i is incremented
}
```

— *end example* ]

<sup>52</sup>) As specified in ??, after a full-expression is evaluated, a sequence of zero or more invocations of destructor functions for temporary objects takes place, usually in reverse order of the construction of each temporary object.

- <sup>11</sup> When calling a function (whether or not the function is inline), every value computation and side effect associated with any argument expression, or with the postfix expression designating the called function, is sequenced before execution of every expression or statement in the body of the called function. For each function invocation  $F$ , for every evaluation  $A$  that occurs within  $F$  and every evaluation  $B$  that does not occur within  $F$  but is evaluated on the same thread and as part of the same signal handler (if any), either  $A$  is sequenced before  $B$  or  $B$  is sequenced before  $A$ .<sup>53</sup> [Note: If  $A$  and  $B$  would not otherwise be sequenced then they are indeterminately sequenced. —end note] Several contexts in C++ cause evaluation of a function call, even though no corresponding function call syntax appears in the translation unit. [Example: Evaluation of a *new-expression* invokes one or more allocation and constructor functions; see ???. For another example, invocation of a conversion function (??) can arise in contexts in which no function call syntax appears. —end example] The sequencing constraints on the execution of the called function (as described above) are features of the function calls as evaluated, whatever the syntax of the expression that calls the function might be.
- <sup>12</sup> If a signal handler is executed as a result of a call to the `std::raise` function, then the execution of the handler is sequenced after the invocation of the `std::raise` function and before its return. [Note: When a signal is received for another reason, the execution of the signal handler is usually unsequenced with respect to the rest of the program. —end note]

### 6.8.2 Multi-threaded executions and data races

[intro.multithread]

- <sup>1</sup> A *thread of execution* (also known as a *thread*) is a single flow of control within a program, including the initial invocation of a specific top-level function, and recursively including every function invocation subsequently executed by the thread. [Note: When one thread creates another, the initial call to the top-level function of the new thread is executed by the new thread, not by the creating thread. —end note] Every thread in a program can potentially access every object and function in a program.<sup>54</sup> Under a hosted implementation, a C++ program can have more than one thread running concurrently. The execution of each thread proceeds as defined by the remainder of this document. The execution of the entire program consists of an execution of all of its threads. [Note: Usually the execution can be viewed as an interleaving of all its threads. However, some kinds of atomic operations, for example, allow executions inconsistent with a simple interleaving, as described below. —end note] Under a freestanding implementation, it is implementation-defined whether a program can have more than one thread of execution.
- <sup>2</sup> For a signal handler that is not executed as a result of a call to the `std::raise` function, it is unspecified which thread of execution contains the signal handler invocation.

#### 6.8.2.1 Data races

[intro.races]

- <sup>1</sup> The value of an object visible to a thread  $T$  at a particular point is the initial value of the object, a value assigned to the object by  $T$ , or a value assigned to the object by another thread, according to the rules below. [Note: In some cases, there may instead be undefined behavior. Much of this subclause is motivated by the desire to support atomic operations with explicit and detailed visibility constraints. However, it also implicitly supports a simpler view for more restricted programs. —end note]
- <sup>2</sup> Two expression evaluations *conflict* if one of them modifies a memory location (??) and the other one reads or modifies the same memory location.
- <sup>3</sup> The library defines a number of atomic operations (??) and operations on mutexes (??) that are specially identified as synchronization operations. These operations play a special role in making assignments in

53) In other words, function executions do not interleave with each other.

54) An object with automatic or thread storage duration (??) is associated with one specific thread, and can be accessed by a different thread only indirectly through a pointer or reference (??).

one thread visible to another. A synchronization operation on one or more memory locations is either a consume operation, an acquire operation, a release operation, or both an acquire and release operation. A synchronization operation without an associated memory location is a fence and can be either an acquire fence, a release fence, or both an acquire and release fence. In addition, there are relaxed atomic operations, which are not synchronization operations, and atomic read-modify-write operations, which have special characteristics. [Note: For example, a call that acquires a mutex will perform an acquire operation on the locations comprising the mutex. Correspondingly, a call that releases the same mutex will perform a release operation on those same locations. Informally, performing a release operation on  $A$  forces prior side effects on other memory locations to become visible to other threads that later perform a consume or an acquire operation on  $A$ . “Relaxed” atomic operations are not synchronization operations even though, like synchronization operations, they cannot contribute to data races. —end note]

- 4 All modifications to a particular atomic object  $M$  occur in some particular total order, called the *modification order* of  $M$ . [Note: There is a separate order for each atomic object. There is no requirement that these can be combined into a single total order for all objects. In general this will be impossible since different threads may observe modifications to different objects in inconsistent orders. —end note]
- 5 A *release sequence* headed by a release operation  $A$  on an atomic object  $M$  is a maximal contiguous subsequence of side effects in the modification order of  $M$ , where the first operation is  $A$ , and every subsequent operation
  - (5.1) — is performed by the same thread that performed  $A$ , or
  - (5.2) — is an atomic read-modify-write operation.

- 6 Certain library calls *synchronize with* other library calls performed by another thread. For example, an atomic store-release synchronizes with a load-acquire that takes its value from the store (??). [Note: Except in the specified cases, reading a later value does not necessarily ensure visibility as described below. Such a requirement would sometimes interfere with efficient implementation. —end note] [Note: The specifications of the synchronization operations define when one reads the value written by another. For atomic objects, the definition is clear. All operations on a given mutex occur in a single total order. Each mutex acquisition “reads the value written” by the last mutex release. —end note]

- 7 An evaluation  $A$  *carries a dependency* to an evaluation  $B$  if

- (7.1) — the value of  $A$  is used as an operand of  $B$ , unless:
  - (7.1.1) —  $B$  is an invocation of any specialization of `std::kill_dependency` (??), or
  - (7.1.2) —  $A$  is the left operand of a built-in logical AND (`&&`, see ??) or logical OR (`||`, see ??) operator, or
  - (7.1.3) —  $A$  is the left operand of a conditional (`? :`, see ??) operator, or
  - (7.1.4) —  $A$  is the left operand of the built-in comma (,) operator (??);
- or
- (7.2) —  $A$  writes a scalar object or bit-field  $M$ ,  $B$  reads the value written by  $A$  from  $M$ , and  $A$  is sequenced before  $B$ , or
- (7.3) — for some evaluation  $X$ ,  $A$  carries a dependency to  $X$ , and  $X$  carries a dependency to  $B$ .

[Note: “Carries a dependency to” is a subset of “is sequenced before”, and is similarly strictly intra-thread. —end note]

- 8 An evaluation  $A$  is *dependency-ordered before* an evaluation  $B$  if

- (8.1) —  $A$  performs a release operation on an atomic object  $M$ , and, in another thread,  $B$  performs a consume operation on  $M$  and reads a value written by any side effect in the release sequence headed by  $A$ , or
- (8.2) — for some evaluation  $X$ ,  $A$  is dependency-ordered before  $X$  and  $X$  carries a dependency to  $B$ .

[*Note:* The relation “is dependency-ordered before” is analogous to “synchronizes with”, but uses release/consume in place of release/acquire. — *end note*]

- <sup>9</sup> An evaluation  $A$  *inter-thread happens before* an evaluation  $B$  if

- (9.1) —  $A$  synchronizes with  $B$ , or
- (9.2) —  $A$  is dependency-ordered before  $B$ , or
- (9.3) — for some evaluation  $X$ 
  - (9.3.1) —  $A$  synchronizes with  $X$  and  $X$  is sequenced before  $B$ , or
  - (9.3.2) —  $A$  is sequenced before  $X$  and  $X$  inter-thread happens before  $B$ , or
  - (9.3.3) —  $A$  inter-thread happens before  $X$  and  $X$  inter-thread happens before  $B$ .

[*Note:* The “inter-thread happens before” relation describes arbitrary concatenations of “sequenced before”, “synchronizes with” and “dependency-ordered before” relationships, with two exceptions. The first exception is that a concatenation is not permitted to end with “dependency-ordered before” followed by “sequenced before”. The reason for this limitation is that a consume operation participating in a “dependency-ordered before” relationship provides ordering only with respect to operations to which this consume operation actually carries a dependency. The reason that this limitation applies only to the end of such a concatenation is that any subsequent release operation will provide the required ordering for a prior consume operation. The second exception is that a concatenation is not permitted to consist entirely of “sequenced before”. The reasons for this limitation are (1) to permit “inter-thread happens before” to be transitively closed and (2) the “happens before” relation, defined below, provides for relationships consisting entirely of “sequenced before”. — *end note*]

- <sup>10</sup> An evaluation  $A$  *happens before* an evaluation  $B$  (or, equivalently,  $B$  *happens after A*) if:

- (10.1) —  $A$  is sequenced before  $B$ , or
- (10.2) —  $A$  inter-thread happens before  $B$ .

The implementation shall ensure that no program execution demonstrates a cycle in the “happens before” relation. [*Note:* This cycle would otherwise be possible only through the use of consume operations. — *end note*]

- <sup>11</sup> An evaluation  $A$  *strongly happens before* an evaluation  $B$  if either

- (11.1) —  $A$  is sequenced before  $B$ , or
- (11.2) —  $A$  synchronizes with  $B$ , or
- (11.3) —  $A$  strongly happens before  $X$  and  $X$  strongly happens before  $B$ .

[*Note:* In the absence of consume operations, the happens before and strongly happens before relations are identical. Strongly happens before essentially excludes consume operations. — *end note*]

- <sup>12</sup> A *visible side effect*  $A$  on a scalar object or bit-field  $M$  with respect to a value computation  $B$  of  $M$  satisfies the conditions:

- (12.1) —  $A$  happens before  $B$  and
- (12.2) — there is no other side effect  $X$  to  $M$  such that  $A$  happens before  $X$  and  $X$  happens before  $B$ .

The value of a non-atomic scalar object or bit-field  $M$ , as determined by evaluation  $B$ , shall be the value stored by the visible side effect  $A$ . [ *Note:* If there is ambiguity about which side effect to a non-atomic object or bit-field is visible, then the behavior is either unspecified or undefined. — *end note* ] [ *Note:* This states that operations on ordinary objects are not visibly reordered. This is not actually detectable without data races, but it is necessary to ensure that data races, as defined below, and with suitable restrictions on the use of atomics, correspond to data races in a simple interleaved (sequentially consistent) execution. — *end note* ]

- <sup>13</sup> The value of an atomic object  $M$ , as determined by evaluation  $B$ , shall be the value stored by some side effect  $A$  that modifies  $M$ , where  $B$  does not happen before  $A$ . [ *Note:* The set of such side effects is also restricted by the rest of the rules described here, and in particular, by the coherence requirements below. — *end note* ]
- <sup>14</sup> If an operation  $A$  that modifies an atomic object  $M$  happens before an operation  $B$  that modifies  $M$ , then  $A$  shall be earlier than  $B$  in the modification order of  $M$ . [ *Note:* This requirement is known as write-write coherence. — *end note* ]
- <sup>15</sup> If a value computation  $A$  of an atomic object  $M$  happens before a value computation  $B$  of  $M$ , and  $A$  takes its value from a side effect  $X$  on  $M$ , then the value computed by  $B$  shall either be the value stored by  $X$  or the value stored by a side effect  $Y$  on  $M$ , where  $Y$  follows  $X$  in the modification order of  $M$ . [ *Note:* This requirement is known as read-read coherence. — *end note* ]
- <sup>16</sup> If a value computation  $A$  of an atomic object  $M$  happens before an operation  $B$  that modifies  $M$ , then  $A$  shall take its value from a side effect  $X$  on  $M$ , where  $X$  precedes  $B$  in the modification order of  $M$ . [ *Note:* This requirement is known as read-write coherence. — *end note* ]
- <sup>17</sup> If a side effect  $X$  on an atomic object  $M$  happens before a value computation  $B$  of  $M$ , then the evaluation  $B$  shall take its value from  $X$  or from a side effect  $Y$  that follows  $X$  in the modification order of  $M$ . [ *Note:* This requirement is known as write-read coherence. — *end note* ]
- <sup>18</sup> [ *Note:* The four preceding coherence requirements effectively disallow compiler reordering of atomic operations to a single object, even if both operations are relaxed loads. This effectively makes the cache coherence guarantee provided by most hardware available to C++ atomic operations. — *end note* ]
- <sup>19</sup> [ *Note:* The value observed by a load of an atomic depends on the “happens before” relation, which depends on the values observed by loads of atomics. The intended reading is that there must exist an association of atomic loads with modifications they observe that, together with suitably chosen modification orders and the “happens before” relation derived as described above, satisfy the resulting constraints as imposed here. — *end note* ]
- <sup>20</sup> Two actions are *potentially concurrent* if
  - (20.1) — they are performed by different threads, or
  - (20.2) — they are unsequenced, at least one is performed by a signal handler, and they are not both performed by the same signal handler invocation.

The execution of a program contains a *data race* if it contains two potentially concurrent conflicting actions, at least one of which is not atomic, and neither happens before the other, except for the special case for signal handlers described below. Any such data race results in undefined behavior. [ *Note:* It can be shown that programs that correctly use mutexes and `memory_order::seq_cst` operations to prevent all data races and use no other synchronization operations behave as if the operations executed by their constituent threads were simply interleaved, with each value computation of an object being taken from the last side effect on that object in that interleaving. This is normally referred to as “sequential consistency”. However, this applies only to data-race-free programs, and data-race-free programs cannot observe most program transformations that

do not change single-threaded program semantics. In fact, most single-threaded program transformations continue to be allowed, since any program that behaves differently as a result must perform an undefined operation. — *end note*]

- 21 Two accesses to the same object of type `volatile std::sig_atomic_t` do not result in a data race if both occur in the same thread, even if one or more occurs in a signal handler. For each signal handler invocation, evaluations performed by the thread invoking a signal handler can be divided into two groups *A* and *B*, such that no evaluations in *B* happen before evaluations in *A*, and the evaluations of such `volatile std::sig_atomic_t` objects take values as though all evaluations in *A* happened before the execution of the signal handler and the execution of the signal handler happened before all evaluations in *B*.
- 22 [ *Note*: Compiler transformations that introduce assignments to a potentially shared memory location that would not be modified by the abstract machine are generally precluded by this document, since such an assignment might overwrite another assignment by a different thread in cases in which an abstract machine execution would not have encountered a data race. This includes implementations of data member assignment that overwrite adjacent members in separate memory locations. Reordering of atomic loads in cases in which the atomics in question may alias is also generally precluded, since this may violate the coherence rules. — *end note* ]
- 23 [ *Note*: Transformations that introduce a speculative read of a potentially shared memory location may not preserve the semantics of the C++ program as defined in this document, since they potentially introduce a data race. However, they are typically valid in the context of an optimizing compiler that targets a specific machine with well-defined semantics for data races. They would be invalid for a hypothetical machine that is not tolerant of races or provides hardware race detection. — *end note* ]

### 6.8.2.2 Forward progress

[[intro.progress](#)]

- 1 The implementation may assume that any thread will eventually do one of the following:
  - (1.1) — terminate,
  - (1.2) — make a call to a library I/O function,
  - (1.3) — perform an access through a volatile glvalue, or
  - (1.4) — perform a synchronization operation or an atomic operation.
- [ *Note*: This is intended to allow compiler transformations such as removal of empty loops, even when termination cannot be proven. — *end note* ]
- 2 Executions of atomic functions that are either defined to be lock-free (??) or indicated as lock-free (??) are *lock-free executions*.
  - (2.1) — If there is only one thread that is not blocked (??) in a standard library function, a lock-free execution in that thread shall complete. [ *Note*: Concurrently executing threads may prevent progress of a lock-free execution. For example, this situation can occur with load-locked store-conditional implementations. This property is sometimes termed obstruction-free. — *end note* ]
  - (2.2) — When one or more lock-free executions run concurrently, at least one should complete. [ *Note*: It is difficult for some implementations to provide absolute guarantees to this effect, since repeated and particularly inopportune interference from other threads may prevent forward progress, e.g., by repeatedly stealing a cache line for unrelated purposes between load-locked and store-conditional instructions. Implementations should ensure that such effects cannot indefinitely delay progress under expected operating conditions, and that such anomalies can therefore safely be ignored by programmers. Outside this document, this property is sometimes termed lock-free. — *end note* ]

- <sup>3</sup> During the execution of a thread of execution, each of the following is termed an *execution step*:
- (3.1) — termination of the thread of execution,
  - (3.2) — performing an access through a volatile glvalue, or
  - (3.3) — completion of a call to a library I/O function, a synchronization operation, or an atomic operation.
- <sup>4</sup> An invocation of a standard library function that blocks (??) is considered to continuously execute execution steps while waiting for the condition that it blocks on to be satisfied. [ *Example*: A library I/O function that blocks until the I/O operation is complete can be considered to continuously check whether the operation is complete. Each such check might consist of one or more execution steps, for example using observable behavior of the abstract machine. — *end example* ]
- <sup>5</sup> [ *Note*: Because of this and the preceding requirement regarding what threads of execution have to perform eventually, it follows that no thread of execution can execute forever without an execution step occurring. — *end note* ]
- <sup>6</sup> A thread of execution *makes progress* when an execution step occurs or a lock-free execution does not complete because there are other concurrent threads that are not blocked in a standard library function (see above).
- <sup>7</sup> For a thread of execution providing *concurrent forward progress guarantees*, the implementation ensures that the thread will eventually make progress for as long as it has not terminated. [ *Note*: This is required regardless of whether or not other threads of executions (if any) have been or are making progress. To eventually fulfill this requirement means that this will happen in an unspecified but finite amount of time. — *end note* ]
- <sup>8</sup> It is implementation-defined whether the implementation-created thread of execution that executes `main` (??) and the threads of execution created by `std::thread` (??) provide concurrent forward progress guarantees. [ *Note*: General-purpose implementations should provide these guarantees. — *end note* ]
- <sup>9</sup> For a thread of execution providing *parallel forward progress guarantees*, the implementation is not required to ensure that the thread will eventually make progress if it has not yet executed any execution step; once this thread has executed a step, it provides concurrent forward progress guarantees.
- <sup>10</sup> [ *Note*: This does not specify a requirement for when to start this thread of execution, which will typically be specified by the entity that creates this thread of execution. For example, a thread of execution that provides concurrent forward progress guarantees and executes tasks from a set of tasks in an arbitrary order, one after the other, satisfies the requirements of parallel forward progress for these tasks. — *end note* ]
- <sup>11</sup> For a thread of execution providing *weakly parallel forward progress guarantees*, the implementation does not ensure that the thread will eventually make progress.
- <sup>12</sup> [ *Note*: Threads of execution providing weakly parallel forward progress guarantees cannot be expected to make progress regardless of whether other threads make progress or not; however, blocking with forward progress guarantee delegation, as defined below, can be used to ensure that such threads of execution make progress eventually. — *end note* ]
- <sup>13</sup> Concurrent forward progress guarantees are stronger than parallel forward progress guarantees, which in turn are stronger than weakly parallel forward progress guarantees. [ *Note*: For example, some kinds of synchronization between threads of execution may only make progress if the respective threads of execution provide parallel forward progress guarantees, but will fail to make progress under weakly parallel guarantees. — *end note* ]
- <sup>14</sup> When a thread of execution  $P$  is specified to *block with forward progress guarantee delegation* on the completion of a set  $S$  of threads of execution, then throughout the whole time of  $P$  being blocked on  $S$ , the implementation

shall ensure that the forward progress guarantees provided by at least one thread of execution in  $S$  is at least as strong as  $P$ 's forward progress guarantees. [ *Note:* It is unspecified which thread or threads of execution in  $S$  are chosen and for which number of execution steps. The strengthening is not permanent and not necessarily in place for the rest of the lifetime of the affected thread of execution. As long as  $P$  is blocked, the implementation has to eventually select and potentially strengthen a thread of execution in  $S$ . — *end note* ] Once a thread of execution in  $S$  terminates, it is removed from  $S$ . Once  $S$  is empty,  $P$  is unblocked.

- <sup>15</sup> [ *Note:* A thread of execution  $B$  thus can temporarily provide an effectively stronger forward progress guarantee for a certain amount of time, due to a second thread of execution  $A$  being blocked on it with forward progress guarantee delegation. In turn, if  $B$  then blocks with forward progress guarantee delegation on  $C$ , this may also temporarily provide a stronger forward progress guarantee to  $C$ . — *end note* ]
- <sup>16</sup> [ *Note:* If all threads of execution in  $S$  finish executing (e.g., they terminate and do not use blocking synchronization incorrectly), then  $P$ 's execution of the operation that blocks with forward progress guarantee delegation will not result in  $P$ 's progress guarantee being effectively weakened. — *end note* ]
- <sup>17</sup> [ *Note:* This does not remove any constraints regarding blocking synchronization for threads of execution providing parallel or weakly parallel forward progress guarantees because the implementation is not required to strengthen a particular thread of execution whose too-weak progress guarantee is preventing overall progress. — *end note* ]
- <sup>18</sup> An implementation should ensure that the last value (in modification order) assigned by an atomic or synchronization operation will become visible to all other threads in a finite period of time.

### 6.8.3 Start and termination

[**basic.start**]

#### 6.8.3.1 main function

[**basic.start.main**]

- <sup>1</sup> A program shall contain a global function called **main**. Executing a program starts a main thread of execution (??, ??) in which the **main** function is invoked, and in which variables of static storage duration might be initialized (??) and destroyed (??). It is implementation-defined whether a program in a freestanding environment is required to define a **main** function. [ *Note:* In a freestanding environment, start-up and termination is implementation-defined; start-up contains the execution of constructors for objects of namespace scope with static storage duration; termination contains the execution of destructors for objects with static storage duration. — *end note* ]
- <sup>2</sup> An implementation shall not predefine the **main** function. This function shall not be overloaded. Its type shall have C++ language linkage and it shall have a declared return type of type **int**, but otherwise its type is implementation-defined. An implementation shall allow both
  - (2.1) — a function of () returning **int** and
  - (2.2) — a function of (**int**, pointer to pointer to **char**) returning **int**

as the type of **main** (??). In the latter form, for purposes of exposition, the first function parameter is called **argc** and the second function parameter is called **argv**, where **argc** shall be the number of arguments passed to the program from the environment in which the program is run. If **argc** is nonzero these arguments shall be supplied in **argv[0]** through **argv[argc-1]** as pointers to the initial characters of null-terminated multibyte strings (NTMBS) (??) and **argv[0]** shall be the pointer to the initial character of a NTMBS that represents the name used to invoke the program or "". The value of **argc** shall be non-negative. The value of **argv[argc]** shall be 0. [ *Note:* It is recommended that any further (optional) parameters be added after **argv**. — *end note* ]

- 3 The function `main` shall not be used within a program. The linkage (??) of `main` is implementation-defined. A program that defines `main` as deleted or that declares `main` to be `inline`, `static`, or `constexpr` is ill-formed. The `main` function shall not be declared with a *linkage-specification* (??). A program that declares a variable `main` at global scope or that declares the name `main` with C language linkage (in any namespace) is ill-formed. The name `main` is not otherwise reserved. [ *Example*: Member functions, classes, and enumerations can be called `main`, as can entities in other namespaces. — *end example* ]
- 4 Terminating the program without leaving the current block (e.g., by calling the function `std::exit(int)` (??)) does not destroy any objects with automatic storage duration (??). If `std::exit` is called to end a program during the destruction of an object with static or thread storage duration, the program has undefined behavior.
- 5 A return statement in `main` has the effect of leaving the main function (destroying any objects with automatic storage duration) and calling `std::exit` with the return value as the argument. If control flows off the end of the *compound-statement* of `main`, the effect is equivalent to a `return` with operand 0 (see also ??).

### 6.8.3.2 Static initialization

[**basic.start.static**]

- 1 Variables with static storage duration are initialized as a consequence of program initiation. Variables with thread storage duration are initialized as a consequence of thread execution. Within each of these phases of initiation, initialization occurs as follows.
- 2 A *constant initializer* for a variable or temporary object `o` is an initializer whose full-expression is a constant expression, except that if `o` is an object, such an initializer may also invoke `constexpr` constructors for `o` and its subobjects even if those objects are of non-literal class types. [ *Note*: Such a class may have a non-trivial destructor. — *end note* ] *Constant initialization* is performed if a variable or temporary object with static or thread storage duration is initialized by a constant initializer for the entity. If constant initialization is not performed, a variable with static storage duration (??) or thread storage duration (??) is zero-initialized (??). Together, zero-initialization and constant initialization are called *static initialization*; all other initialization is *dynamic initialization*. All static initialization strongly happens before (??) any dynamic initialization. [ *Note*: The dynamic initialization of non-local variables is described in ??; that of local static variables is described in ??. — *end note* ]
- 3 An implementation is permitted to perform the initialization of a variable with static or thread storage duration as a static initialization even if such initialization is not required to be done statically, provided that
  - (3.1) — the dynamic version of the initialization does not change the value of any other object of static or thread storage duration prior to its initialization, and
  - (3.2) — the static version of the initialization produces the same value in the initialized variable as would be produced by the dynamic initialization if all variables not required to be initialized statically were initialized dynamically.

[ *Note*: As a consequence, if the initialization of an object `obj1` refers to an object `obj2` of namespace scope potentially requiring dynamic initialization and defined later in the same translation unit, it is unspecified whether the value of `obj2` used will be the value of the fully initialized `obj2` (because `obj2` was statically initialized) or will be the value of `obj2` merely zero-initialized. For example,

```
inline double fd() { return 1.0; }
extern double d1;
double d2 = d1;      // unspecified:
```

```

    // may be statically initialized to 0.0 or
    // dynamically initialized to 0.0 if d1 is
    // dynamically initialized, or 1.0 otherwise
double d1 = fd(); // may be initialized statically or dynamically to 1.0
— end note]

```

### 6.8.3.3 Dynamic initialization of non-local variables

[basic.start.dynamic]

- <sup>1</sup> Dynamic initialization of a non-local variable with static storage duration is unordered if the variable is an implicitly or explicitly instantiated specialization, is partially-ordered if the variable is an inline variable that is not an implicitly or explicitly instantiated specialization, and otherwise is ordered. [ *Note:* An explicitly specialized non-inline static data member or variable template specialization has ordered initialization. — end note ]
- <sup>2</sup> Dynamic initialization of non-local variables V and W with static storage duration are ordered as follows:
  - (2.1) — If V and W have ordered initialization and V is defined before W within a single translation unit, the initialization of V is sequenced before the initialization of W.
  - (2.2) — If V has partially-ordered initialization, W does not have unordered initialization, and V is defined before W in every translation unit in which W is defined, then
    - (2.2.1) — if the program starts a thread (??) other than the main thread (??), the initialization of V strongly happens before the initialization of W;
    - (2.2.2) — otherwise, the initialization of V is sequenced before the initialization of W.
  - (2.3) — Otherwise, if the program starts a thread other than the main thread before either V or W is initialized, it is unspecified in which threads the initializations of V and W occur; the initializations are unsequenced if they occur in the same thread.
  - (2.4) — Otherwise, the initializations of V and W are indeterminately sequenced.

[ *Note:* This definition permits initialization of a sequence of ordered variables concurrently with another sequence. — end note ]

- <sup>3</sup> A *non-initialization odr-use* is an odr-use (??) not caused directly or indirectly by the initialization of a non-local static or thread storage duration variable.
- <sup>4</sup> It is implementation-defined whether the dynamic initialization of a non-local non-inline variable with static storage duration is sequenced before the first statement of `main` or is deferred. If it is deferred, it strongly happens before any non-initialization odr-use of any non-inline function or non-inline variable defined in the same translation unit as the variable to be initialized.<sup>55</sup> It is implementation-defined in which threads and at which points in the program such deferred dynamic initialization occurs. [ *Note:* Such points should be chosen in a way that allows the programmer to avoid deadlocks. — end note ] [ *Example:*

```

// - File 1 -
#include "a.h"
#include "b.h"
B b;
A::A(){
    b.Use();
}

```

<sup>55</sup>) A non-local variable with static storage duration having initialization with side effects is initialized in this case, even if it is not itself odr-used (??, ??).

```
// - File 2 -
#include "a.h"
A a;

// - File 3 -
#include "a.h"
#include "b.h"
extern A a;
extern B b;

int main() {
    a.Use();
    b.Use();
}
```

It is implementation-defined whether either `a` or `b` is initialized before `main` is entered or whether the initializations are delayed until `a` is first odr-used in `main`. In particular, if `a` is initialized before `main` is entered, it is not guaranteed that `b` will be initialized before it is odr-used by the initialization of `a`, that is, before `A::A` is called. If, however, `a` is initialized at some point after the first statement of `main`, `b` will be initialized prior to its use in `A::A`. — *end example*

- 5 It is implementation-defined whether the dynamic initialization of a non-local inline variable with static storage duration is sequenced before the first statement of `main` or is deferred. If it is deferred, it strongly happens before any non-initialization odr-use of that variable. It is implementation-defined in which threads and at which points in the program such deferred dynamic initialization occurs.
- 6 It is implementation-defined whether the dynamic initialization of a non-local non-inline variable with thread storage duration is sequenced before the first statement of the initial function of a thread or is deferred. If it is deferred, the initialization associated with the entity for thread  $t$  is sequenced before the first non-initialization odr-use by  $t$  of any non-inline variable with thread storage duration defined in the same translation unit as the variable to be initialized. It is implementation-defined in which threads and at which points in the program such deferred dynamic initialization occurs.
- 7 If the initialization of a non-local variable with static or thread storage duration exits via an exception, `std::terminate` is called (??).

#### 6.8.3.4 Termination

[**basic.start.term**]

- <sup>1</sup> Destructors (??) for initialized objects (that is, objects whose lifetime (??) has begun) with static storage duration, and functions registered with `std::atexit`, are called as part of a call to `std::exit` (??). The call to `std::exit` is sequenced before the invocations of the destructors and the registered functions. [ *Note:* Returning from `main` invokes `std::exit` (??). — *end note* ]
- 2 Destructors for initialized objects with thread storage duration within a given thread are called as a result of returning from the initial function of that thread and as a result of that thread calling `std::exit`. The completions of the destructors for all initialized objects with thread storage duration within that thread strongly happen before the initiation of the destructors of any object with static storage duration.
- 3 If the completion of the constructor or dynamic initialization of an object with static storage duration strongly happens before that of another, the completion of the destructor of the second is sequenced before the initiation of the destructor of the first. If the completion of the constructor or dynamic initialization of an object with thread storage duration is sequenced before that of another, the completion of the destructor of

the second is sequenced before the initiation of the destructor of the first. If an object is initialized statically, the object is destroyed in the same order as if the object was dynamically initialized. For an object of array or class type, all subobjects of that object are destroyed before any block-scope object with static storage duration initialized during the construction of the subobjects is destroyed. If the destruction of an object with static or thread storage duration exits via an exception, `std::terminate` is called (??).

- 4 If a function contains a block-scope object of static or thread storage duration that has been destroyed and the function is called during the destruction of an object with static or thread storage duration, the program has undefined behavior if the flow of control passes through the definition of the previously destroyed block-scope object. Likewise, the behavior is undefined if the block-scope object is used indirectly (i.e., through a pointer) after its destruction.
- 5 If the completion of the initialization of an object with static storage duration strongly happens before a call to `std::atexit` (see `<cstdlib>`, ??), the call to the function passed to `std::atexit` is sequenced before the call to the destructor for the object. If a call to `std::atexit` strongly happens before the completion of the initialization of an object with static storage duration, the call to the destructor for the object is sequenced before the call to the function passed to `std::atexit`. If a call to `std::atexit` strongly happens before another call to `std::atexit`, the call to the function passed to the second `std::atexit` call is sequenced before the call to the function passed to the first `std::atexit` call.
- 6 If there is a use of a standard library object or function not permitted within signal handlers (??) that does not happen before (??) completion of destruction of objects with static storage duration and execution of `std::atexit` registered functions (??), the program has undefined behavior. [Note: If there is a use of an object with static storage duration that does not happen before the object's destruction, the program has undefined behavior. Terminating every thread before a call to `std::exit` or the exit from `main` is sufficient, but not necessary, to satisfy these requirements. These requirements permit thread managers as static-storage-duration objects. —end note]
- 7 Calling the function `std::abort()` declared in `<cstdlib>` terminates the program without executing any destructors and without calling the functions passed to `std::atexit()` or `std::at_quick_exit()`.

## 7 Standard conversions

[conv]

<sup>1</sup> Standard conversions are implicit conversions with built-in meaning. ?? enumerates the full set of such conversions. A *standard conversion sequence* is a sequence of standard conversions in the following order:

- (1.1) — Zero or one conversion from the following set: lvalue-to-rvalue conversion, array-to-pointer conversion, and function-to-pointer conversion.
- (1.2) — Zero or one conversion from the following set: integral promotions, floating-point promotion, integral conversions, floating-point conversions, floating-integral conversions, pointer conversions, pointer-to-member conversions, and boolean conversions.
- (1.3) — Zero or one function pointer conversion.
- (1.4) — Zero or one qualification conversion.

[*Note*: A standard conversion sequence can be empty, i.e., it can consist of no conversions. —end note]  
A standard conversion sequence will be applied to an expression if necessary to convert it to a required destination type.

<sup>2</sup> [*Note*: Expressions with a given type will be implicitly converted to other types in several contexts:

- (2.1) — When used as operands of operators. The operator's requirements for its operands dictate the destination type (??).
- (2.2) — When used in the condition of an **if** statement or iteration statement (??, ??). The destination type is **bool**.
- (2.3) — When used in the expression of a **switch** statement. The destination type is integral (??).
- (2.4) — When used as the source expression for an initialization (which includes use as an argument in a function call and use as the expression in a **return** statement). The type of the entity being initialized is (generally) the destination type. See ??, ??.

—end note]

<sup>3</sup> An expression **e** can be *implicitly converted* to a type **T** if and only if the declaration **T t=e;** is well-formed, for some invented temporary variable **t** (??).

<sup>4</sup> Certain language constructs require that an expression be converted to a Boolean value. An expression **e** appearing in such a context is said to be *contextually converted to bool* and is well-formed if and only if the declaration **bool t(e);** is well-formed, for some invented temporary variable **t** (??).

<sup>5</sup> Certain language constructs require conversion to a value having one of a specified set of types appropriate to the construct. An expression **e** of class type **E** appearing in such a context is said to be *contextually implicitly converted* to a specified type **T** and is well-formed if and only if **e** can be implicitly converted to a type **T** that is determined as follows: **E** is searched for non-explicit conversion functions whose return type is *cv T* or reference to *cv T* such that **T** is allowed by the context. There shall be exactly one such **T**.

<sup>6</sup> The effect of any implicit conversion is the same as performing the corresponding declaration and initialization and then using the temporary variable as the result of the conversion. The result is an lvalue if **T** is an lvalue reference type or an rvalue reference to function type (??), an xvalue if **T** is an rvalue reference to object

type, and a prvalue otherwise. The expression `e` is used as a glvalue if and only if the initialization uses it as a glvalue.

- <sup>7</sup> [Note: For class types, user-defined conversions are considered as well; see [??](#). In general, an implicit conversion sequence ([??](#)) consists of a standard conversion sequence followed by a user-defined conversion followed by another standard conversion sequence. —end note]
- <sup>8</sup> [Note: There are some contexts where certain conversions are suppressed. For example, the lvalue-to-rvalue conversion is not done on the operand of the unary `&` operator. Specific exceptions are given in the descriptions of those operators and contexts. —end note]

## 7.1 Lvalue-to-rvalue conversion

[[conv.lval](#)]

- <sup>1</sup> A glvalue ([??](#)) of a non-function, non-array type `T` can be converted to a prvalue.<sup>56</sup> If `T` is an incomplete type, a program that necessitates this conversion is ill-formed. If `T` is a non-class type, the type of the prvalue is the cv-unqualified version of `T`. Otherwise, the type of the prvalue is `T`.<sup>57</sup>
- <sup>2</sup> When an lvalue-to-rvalue conversion is applied to an expression `e`, and either
  - (2.1) — `e` is not potentially evaluated, or
  - (2.2) — the evaluation of `e` results in the evaluation of a member `ex` of the set of potential results of `e`, and `ex` names a variable `x` that is not odr-used by `ex` ([??](#)),

the value contained in the referenced object is not accessed. [Example:

```
struct S { int n; };
auto f() {
    S x { 1 };
    constexpr S y { 2 };
    return [&](bool b) { return (b ? y : x).n; };
}
auto g = f();
int m = g(false);    // undefined behavior due to access of x.n outside its lifetime
int n = g(true);    // OK, does not access y.n
— end example]
```

- <sup>3</sup> The result of the conversion is determined according to the following rules:
  - (3.1) — If `T` is `cv std::nullptr_t`, the result is a null pointer constant ([??](#)). [Note: Since no value is fetched from memory, there is no side effect for a volatile access ([??](#)), and an inactive member of a union ([??](#)) may be accessed. —end note]
  - (3.2) — Otherwise, if `T` has a class type, the conversion copy-initializes the result object from the glvalue.
  - (3.3) — Otherwise, if the object to which the glvalue refers contains an invalid pointer value ([??](#), [??](#)), the behavior is implementation-defined.
  - (3.4) — Otherwise, the value contained in the object indicated by the glvalue is the prvalue result.

- <sup>4</sup> [Note: See also [??](#). —end note]

---

<sup>56</sup>) For historical reasons, this conversion is called the “lvalue-to-rvalue” conversion, even though that name does not accurately reflect the taxonomy of expressions described in [??](#).

<sup>57</sup>) In C++ class and array prvalues can have cv-qualified types. This differs from ISO C, in which non-lvalues never have cv-qualified types.

## 7.2 Array-to-pointer conversion

[conv.array]

- <sup>1</sup> An lvalue or rvalue of type “array of N T” or “array of unknown bound of T” can be converted to a prvalue of type “pointer to T”. The temporary materialization conversion (??) is applied. The result is a pointer to the first element of the array.

## 7.3 Function-to-pointer conversion

[conv.func]

- <sup>1</sup> An lvalue of function type T can be converted to a prvalue of type “pointer to T”. The result is a pointer to the function.<sup>58</sup>
- <sup>2</sup> [ *Note:* See ?? for additional rules for the case where the function is overloaded. —end note]

## 7.4 Temporary materialization conversion

[conv.rval]

- <sup>1</sup> A prvalue of type T can be converted to an xvalue of type T. This conversion initializes a temporary object (??) of type T from the prvalue by evaluating the prvalue with the temporary object as its result object, and produces an xvalue denoting the temporary object. T shall be a complete type. [ *Note:* If T is a class type (or array thereof), it must have an accessible and non-deleted destructor; see ???. —end note] [ *Example:*

```
struct X { int n; };
int k = X().n;      // OK, X() prvalue is converted to xvalue
— end example ]
```

## 7.5 Qualification conversions

[conv.qual]

- <sup>1</sup> A cv-decomposition of a type T is a sequence of  $cv_i$  and  $P_i$  such that T is

“ $cv_0 P_0 cv_1 P_1 \dots cv_{n-1} P_{n-1} cv_n U$ ” for  $n > 0$ ,

where each  $cv_i$  is a set of cv-qualifiers (??), and each  $P_i$  is “pointer to” (??), “pointer to member of class  $C_i$  of type” (??), “array of  $N_i$ ”, or “array of unknown bound of” (??). If  $P_i$  designates an array, the cv-qualifiers  $cv_{i+1}$  on the element type are also taken as the cv-qualifiers  $cv_i$  of the array. [ *Example:* The type denoted by the type-id `const int **` has two cv-decompositions, taking U as “int” and as “pointer to `const int`”. —end example] The  $n$ -tuple of cv-qualifiers after the first one in the longest cv-decomposition of T, that is,  $cv_1, cv_2, \dots, cv_n$ , is called the cv-qualification signature of T.

- <sup>2</sup> Two types  $T_1$  and  $T_2$  are similar if they have cv-decompositions with the same  $n$  such that corresponding  $P_i$  components are the same and the types denoted by U are the same.
- <sup>3</sup> A prvalue expression of type  $T_1$  can be converted to type  $T_2$  if the following conditions are satisfied, where  $cv_i^j$  denotes the cv-qualifiers in the cv-qualification signature of  $T_j$ :<sup>59</sup>
- (3.1) —  $T_1$  and  $T_2$  are similar.
  - (3.2) — For every  $i > 0$ , if `const` is in  $cv_i^1$  then `const` is in  $cv_i^2$ , and similarly for `volatile`.
  - (3.3) — If the  $cv_i^1$  and  $cv_i^2$  are different, then `const` is in every  $cv_k^2$  for  $0 < k < i$ .

[ *Note:* If a program could assign a pointer of type `T**` to a pointer of type `const T**` (that is, if line #1 below were allowed), a program could inadvertently modify a const object (as it is done on line #2). For example,

```
int main() {
    const char c = 'c';
```

<sup>58</sup>) This conversion never applies to non-static member functions because an lvalue that refers to a non-static member function cannot be obtained.

<sup>59</sup>) These rules ensure that const-safety is preserved by the conversion.

```

char* pc;
const char** pcc = &pc;           // #1: not allowed
*pcc = &c;
*pc = 'C';                     // #2: modifies a const object
}
— end note]

```

- <sup>4</sup> [Note: A prvalue of type “pointer to *cv1 T*” can be converted to a prvalue of type “pointer to *cv2 T*” if “*cv2 T*” is more cv-qualified than “*cv1 T*”. A prvalue of type “pointer to member of *X* of type *cv1 T*” can be converted to a prvalue of type “pointer to member of *X* of type *cv2 T*” if “*cv2 T*” is more cv-qualified than “*cv1 T*”. — end note]
- <sup>5</sup> [Note: Function types (including those used in pointer to member function types) are never cv-qualified (??). — end note]

## 7.6 Integral promotions

[conv.prom]

- <sup>1</sup> A prvalue of an integer type other than `bool`, `char16_t`, `char32_t`, or `wchar_t` whose integer conversion rank (??) is less than the rank of `int` can be converted to a prvalue of type `int` if `int` can represent all the values of the source type; otherwise, the source prvalue can be converted to a prvalue of type `unsigned int`.
- <sup>2</sup> A prvalue of type `char16_t`, `char32_t`, or `wchar_t` (??) can be converted to a prvalue of the first of the following types that can represent all the values of its underlying type: `int`, `unsigned int`, `long int`, `unsigned long int`, `long long int`, or `unsigned long long int`. If none of the types in that list can represent all the values of its underlying type, a prvalue of type `char16_t`, `char32_t`, or `wchar_t` can be converted to a prvalue of its underlying type.
- <sup>3</sup> A prvalue of an unscoped enumeration type whose underlying type is not fixed (??) can be converted to a prvalue of the first of the following types that can represent all the values of the enumeration (i.e., the values in the range  $b_{\min}$  to  $b_{\max}$  as described in ??): `int`, `unsigned int`, `long int`, `unsigned long int`, `long long int`, or `unsigned long long int`. If none of the types in that list can represent all the values of the enumeration, a prvalue of an unscoped enumeration type can be converted to a prvalue of the extended integer type with lowest integer conversion rank (??) greater than the rank of `long long` in which all the values of the enumeration can be represented. If there are two such extended types, the signed one is chosen.
- <sup>4</sup> A prvalue of an unscoped enumeration type whose underlying type is fixed (??) can be converted to a prvalue of its underlying type. Moreover, if integral promotion can be applied to its underlying type, a prvalue of an unscoped enumeration type whose underlying type is fixed can also be converted to a prvalue of the promoted underlying type.
- <sup>5</sup> A prvalue for an integral bit-field (??) can be converted to a prvalue of type `int` if `int` can represent all the values of the bit-field; otherwise, it can be converted to `unsigned int` if `unsigned int` can represent all the values of the bit-field. If the bit-field is larger yet, no integral promotion applies to it. If the bit-field has an enumerated type, it is treated as any other value of that type for promotion purposes.
- <sup>6</sup> A prvalue of type `bool` can be converted to a prvalue of type `int`, with `false` becoming zero and `true` becoming one.
- <sup>7</sup> These conversions are called *integral promotions*.

## 7.7 Floating-point promotion

[conv.fpprom]

- <sup>1</sup> A prvalue of type `float` can be converted to a prvalue of type `double`. The value is unchanged.

- <sup>2</sup> This conversion is called *floating-point promotion*.

## 7.8 Integral conversions

[conv.integral]

- <sup>1</sup> A prvalue of an integer type can be converted to a prvalue of another integer type. A prvalue of an unscoped enumeration type can be converted to a prvalue of an integer type.
- <sup>2</sup> If the destination type is unsigned, the resulting value is the least unsigned integer congruent to the source integer (modulo  $2^n$  where  $n$  is the number of bits used to represent the unsigned type). [Note: In a two's complement representation, this conversion is conceptual and there is no change in the bit pattern (if there is no truncation). —end note]
- <sup>3</sup> If the destination type is signed, the value is unchanged if it can be represented in the destination type; otherwise, the value is implementation-defined.
- <sup>4</sup> If the destination type is `bool`, see [??](#). If the source type is `bool`, the value `false` is converted to zero and the value `true` is converted to one.
- <sup>5</sup> The conversions allowed as integral promotions are excluded from the set of integral conversions.

## 7.9 Floating-point conversions

[conv.double]

- <sup>1</sup> A prvalue of floating-point type can be converted to a prvalue of another floating-point type. If the source value can be exactly represented in the destination type, the result of the conversion is that exact representation. If the source value is between two adjacent destination values, the result of the conversion is an implementation-defined choice of either of those values. Otherwise, the behavior is undefined.
- <sup>2</sup> The conversions allowed as floating-point promotions are excluded from the set of floating-point conversions.

## 7.10 Floating-integral conversions

[conv.fpint]

- <sup>1</sup> A prvalue of a floating-point type can be converted to a prvalue of an integer type. The conversion truncates; that is, the fractional part is discarded. The behavior is undefined if the truncated value cannot be represented in the destination type. [Note: If the destination type is `bool`, see [??](#). —end note]
- <sup>2</sup> A prvalue of an integer type or of an unscoped enumeration type can be converted to a prvalue of a floating-point type. The result is exact if possible. If the value being converted is in the range of values that can be represented but the value cannot be represented exactly, it is an implementation-defined choice of either the next lower or higher representable value. [Note: Loss of precision occurs if the integral value cannot be represented exactly as a value of the floating type. —end note] If the value being converted is outside the range of values that can be represented, the behavior is undefined. If the source type is `bool`, the value `false` is converted to zero and the value `true` is converted to one.

## 7.11 Pointer conversions

[conv.ptr]

- <sup>1</sup> A *null pointer constant* is an integer literal ([??](#)) with value zero or a prvalue of type `std::nullptr_t`. A null pointer constant can be converted to a pointer type; the result is the null pointer value of that type ([??](#)) and is distinguishable from every other value of object pointer or function pointer type. Such a conversion is called a *null pointer conversion*. Two null pointer values of the same type shall compare equal. The conversion of a null pointer constant to a pointer to cv-qualified type is a single conversion, and not the sequence of a pointer conversion followed by a qualification conversion ([??](#)). A null pointer constant of integral type can be converted to a prvalue of type `std::nullptr_t`. [Note: The resulting prvalue is not a null pointer value. —end note]

- 2 A prvalue of type “pointer to *cv T*”, where *T* is an object type, can be converted to a prvalue of type “pointer to *cv void*”. The pointer value (??) is unchanged by this conversion.
- 3 A prvalue of type “pointer to *cv D*”, where *D* is a class type, can be converted to a prvalue of type “pointer to *cv B*”, where *B* is a base class (??) of *D*. If *B* is an inaccessible (??) or ambiguous (??) base class of *D*, a program that necessitates this conversion is ill-formed. The result of the conversion is a pointer to the base class subobject of the derived class object. The null pointer value is converted to the null pointer value of the destination type.

## 7.12 Pointer-to-member conversions

[conv.mem]

- 1 A null pointer constant (??) can be converted to a pointer-to-member type; the result is the *null member pointer value* of that type and is distinguishable from any pointer to member not created from a null pointer constant. Such a conversion is called a *null member pointer conversion*. Two null member pointer values of the same type shall compare equal. The conversion of a null pointer constant to a pointer to member of cv-qualified type is a single conversion, and not the sequence of a pointer-to-member conversion followed by a qualification conversion (??).
- 2 A prvalue of type “pointer to member of *B* of type *cv T*”, where *B* is a class type, can be converted to a prvalue of type “pointer to member of *D* of type *cv T*”, where *D* is a derived class (??) of *B*. If *B* is an inaccessible (??), ambiguous (??), or virtual (??) base class of *D*, or a base class of a virtual base class of *D*, a program that necessitates this conversion is ill-formed. The result of the conversion refers to the same member as the pointer to member before the conversion took place, but it refers to the base class member as if it were a member of the derived class. The result refers to the member in *D*'s instance of *B*. Since the result has type “pointer to member of *D* of type *cv T*”, indirection through it with a *D* object is valid. The result is the same as if indirecting through the pointer to member of *B* with the *B* subobject of *D*. The null member pointer value is converted to the null member pointer value of the destination type.<sup>60</sup>

## 7.13 Function pointer conversions

[conv.fctptr]

- 1 A prvalue of type “pointer to `noexcept` function” can be converted to a prvalue of type “pointer to function”. The result is a pointer to the function. A prvalue of type “pointer to member of type `noexcept` function” can be converted to a prvalue of type “pointer to member of type function”. The result points to the member function.

[*Example*:

```
void (*p)();
void (**pp)() noexcept = &p; // error: cannot convert to pointer to noexcept function

struct S { typedef void (*p)(); operator p(); };
void (*q)() noexcept = S(); // error: cannot convert to pointer to noexcept function
```

— *end example*]

## 7.14 Boolean conversions

[conv.bool]

- 1 A prvalue of arithmetic, unscoped enumeration, pointer, or pointer-to-member type can be converted to a prvalue of type `bool`. A zero value, null pointer value, or null member pointer value is converted to `false`;

<sup>60)</sup> The rule for conversion of pointers to members (from pointer to member of base to pointer to member of derived) appears inverted compared to the rule for pointers to objects (from pointer to derived to pointer to base) (??, ??). This inversion is necessary to ensure type safety. Note that a pointer to member is not an object pointer or a function pointer and the rules for conversions of such pointers do not apply to pointers to members. In particular, a pointer to member cannot be converted to a `void*`.

any other value is converted to `true`. For direct-initialization (??), a prvalue of type `std::nullptr_t` can be converted to a prvalue of type `bool`; the resulting value is `false`.

# 8 Expressions

[expr]

## 8.1 Preamble

[expr.pre]

- 1 [Note: ?? defines the syntax, order of evaluation, and meaning of expressions.<sup>61</sup> An expression is a sequence of operators and operands that specifies a computation. An expression can result in a value and can cause side effects. —end note]
- 2 [Note: Operators can be overloaded, that is, given meaning when applied to expressions of class type (??) or enumeration type (??). Uses of overloaded operators are transformed into function calls as described in ?. Overloaded operators obey the rules for syntax and evaluation order specified in ??, but the requirements of operand type and value category are replaced by the rules for function call. Relations between operators, such as `++a` meaning `a+=1`, are not guaranteed for overloaded operators (??). —end note]
- 3 Subclause ?? defines the effects of operators when applied to types for which they have not been overloaded. Operator overloading shall not modify the rules for the *built-in operators*, that is, for operators applied to types for which they are defined by this Standard. However, these built-in operators participate in overload resolution, and as part of that process user-defined conversions will be considered where necessary to convert the operands to types appropriate for the built-in operator. If a built-in operator is selected, such conversions will be applied to the operands before the operation is considered further according to the rules in subclause ??; see ??, ??.
- 4 If during the evaluation of an expression, the result is not mathematically defined or not in the range of representable values for its type, the behavior is undefined. [Note: Treatment of division by zero, forming a remainder using a zero divisor, and all floating-point exceptions vary among machines, and is sometimes adjustable by a library function. —end note]
- 5 The values of the floating operands and the results of floating expressions may be represented in greater precision and range than that required by the type; the types are not changed thereby.<sup>62</sup>

## 8.2 Properties of expressions

[expr.prop]

### 8.2.1 Value category

[basic.lval]

- 1 Expressions are categorized according to the taxonomy in Figure ??.

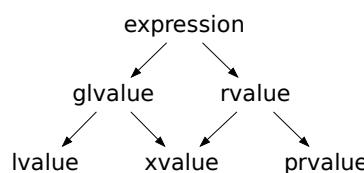

Figure 1 — Expression category taxonomy

- (1.1) — A *gvalue* is an expression whose evaluation determines the identity of an object, bit-field, or function.

<sup>61</sup>) The precedence of operators is not directly specified, but it can be derived from the syntax.

<sup>62</sup>) The cast and assignment operators must still perform their specific conversions as described in ??, ?? and ??.

- (1.2) — A *prvalue* is an expression whose evaluation initializes an object or a bit-field, or computes the value of the operand of an operator, as specified by the context in which it appears.
  - (1.3) — An *xvalue* is a glvalue that denotes an object or bit-field whose resources can be reused (usually because it is near the end of its lifetime). [ *Example*: Certain kinds of expressions involving rvalue references (??) yield xvalues, such as a call to a function whose return type is an rvalue reference or a cast to an rvalue reference type. — *end example* ]
  - (1.4) — An *lvalue* is a glvalue that is not an xvalue.
  - (1.5) — An *rvalue* is a prvalue or an xvalue.
- 2 Every expression belongs to exactly one of the fundamental classifications in this taxonomy: lvalue, xvalue, or prvalue. This property of an expression is called its *value category*. [ *Note*: The discussion of each built-in operator in ?? indicates the category of the value it yields and the value categories of the operands it expects. For example, the built-in assignment operators expect that the left operand is an lvalue and that the right operand is a prvalue and yield an lvalue as the result. User-defined operators are functions, and the categories of values they expect and yield are determined by their parameter and return types. — *end note* ]
- 3 [ *Note*: Historically, lvalues and rvalues were so-called because they could appear on the left- and right-hand side of an assignment (although this is no longer generally true); glvalues are “generalized” lvalues, prvalues are “pure” rvalues, and xvalues are “eXpiring” lvalues. Despite their names, these terms classify expressions, not values. — *end note* ]
- 4 [ *Note*: An expression is an xvalue if it is:
- (4.1) — the result of calling a function, whether implicitly or explicitly, whose return type is an rvalue reference to object type,
  - (4.2) — a cast to an rvalue reference to object type,
  - (4.3) — a class member access expression designating a non-static data member of non-reference type in which the object expression is an xvalue, or
  - (4.4) — a `.*` pointer-to-member expression in which the first operand is an xvalue and the second operand is a pointer to data member.

In general, the effect of this rule is that named rvalue references are treated as lvalues and unnamed rvalue references to objects are treated as xvalues; rvalue references to functions are treated as lvalues whether named or not. — *end note* ]

[ *Example*:

```
struct A {
    int m;
};

A&& operator+(A, A);
A&& f();

A a;
A&& ar = static_cast<A&&>(a);
```

The expressions `f()`, `f().m`, `static_cast<A&&>(a)`, and `a + a` are xvalues. The expression `ar` is an lvalue. — *end example* ]

- 5 The *result* of a prvalue is the value that the expression stores into its context. A prvalue whose result is the value *V* is sometimes said to have or name the value *V*. The *result object* of a prvalue is the object initialized

by the prvalue; a prvalue that is used to compute the value of an operand of an operator or that has type *cv void* has no result object. [Note: Except when the prvalue is the operand of a *decltype-specifier*, a prvalue of class or array type always has a result object. For a discarded prvalue, a temporary object is materialized; see ???. —end note] The *result* of a glvalue is the entity denoted by the expression.

- 6 Whenever a glvalue expression appears as an operand of an operator that expects a prvalue for that operand, the lvalue-to-rvalue (??), array-to-pointer (??), or function-to-pointer (??) standard conversions are applied to convert the expression to a prvalue. [Note: An attempt to bind an rvalue reference to an lvalue is not such a context; see ???. —end note] [Note: Because cv-qualifiers are removed from the type of an expression of non-class type when the expression is converted to a prvalue, an lvalue expression of type `const int` can, for example, be used where a prvalue expression of type `int` is required. —end note] [Note: There are no prvalue bit-fields; if a bit-field is converted to a prvalue (??), a prvalue of the type of the bit-field is created, which might then be promoted (??). —end note]
- 7 Whenever a prvalue expression appears as an operand of an operator that expects a glvalue for that operand, the temporary materialization conversion (??) is applied to convert the expression to an xvalue.
- 8 The discussion of reference initialization in ?? and of temporaries in ?? indicates the behavior of lvalues and rvalues in other significant contexts.
- 9 Unless otherwise indicated (??), a prvalue shall always have complete type or the `void` type. A glvalue shall not have type *cv void*. [Note: A glvalue may have complete or incomplete non-`void` type. Class and array prvalues can have cv-qualified types; other prvalues always have cv-unqualified types. See ???. —end note]
- 10 An lvalue is *modifiable* unless its type is const-qualified or is a function type. [Note: A program that attempts to modify an object through a nonmodifiable lvalue expression or through an rvalue expression is ill-formed (??, ??, ??). —end note]
- 11 If a program attempts to access the stored value of an object through a glvalue of other than one of the following types the behavior is undefined:<sup>63</sup>
  - (11.1) — the dynamic type of the object,
  - (11.2) — a cv-qualified version of the dynamic type of the object,
  - (11.3) — a type similar (as defined in ??) to the dynamic type of the object,
  - (11.4) — a type that is the signed or unsigned type corresponding to the dynamic type of the object,
  - (11.5) — a type that is the signed or unsigned type corresponding to a cv-qualified version of the dynamic type of the object,
  - (11.6) — an aggregate or union type that includes one of the aforementioned types among its elements or non-static data members (including, recursively, an element or non-static data member of a subaggregate or contained union),
  - (11.7) — a type that is a (possibly cv-qualified) base class type of the dynamic type of the object,
  - (11.8) — a `char`, `unsigned char`, or `std::byte` type.

### 8.2.2 Type

[expr.type]

- 1 If an expression initially has the type “reference to T” (??, ??), the type is adjusted to T prior to any further analysis. The expression designates the object or function denoted by the reference, and the expression is an lvalue or an xvalue, depending on the expression. [Note: Before the lifetime of the reference has started or after it has ended, the behavior is undefined (see ??). —end note]

<sup>63</sup>) The intent of this list is to specify those circumstances in which an object may or may not be aliased.

- <sup>2</sup> If a prvalue initially has the type “cv T”, where T is a cv-unqualified non-class, non-array type, the type of the expression is adjusted to T prior to any further analysis.
- <sup>3</sup> The *cv-combined type* of two types T<sub>1</sub> and T<sub>2</sub> is a type T<sub>3</sub> similar to T<sub>1</sub> whose cv-qualification signature (??) is:

- (3.1) — for every  $i > 0$ , cv<sub>i</sub><sup>3</sup> is the union of cv<sub>i</sub><sup>1</sup> and cv<sub>i</sub><sup>2</sup>;
- (3.2) — if the resulting cv<sub>i</sub><sup>3</sup> is different from cv<sub>i</sub><sup>1</sup> or cv<sub>i</sub><sup>2</sup>, then **const** is added to every cv<sub>k</sub><sup>3</sup> for  $0 < k < i$ .

[*Note*: Given similar types T<sub>1</sub> and T<sub>2</sub>, this construction ensures that both can be converted to T<sub>3</sub>. — *end note*]

- <sup>4</sup> The *composite pointer type* of two operands p<sub>1</sub> and p<sub>2</sub> having types T<sub>1</sub> and T<sub>2</sub>, respectively, where at least one is a pointer or pointer-to-member type or std::nullptr\_t, is:

- (4.1) — if both p<sub>1</sub> and p<sub>2</sub> are null pointer constants, std::nullptr\_t;
- (4.2) — if either p<sub>1</sub> or p<sub>2</sub> is a null pointer constant, T<sub>2</sub> or T<sub>1</sub>, respectively;
- (4.3) — if T<sub>1</sub> or T<sub>2</sub> is “pointer to cv1 void” and the other type is “pointer to cv2 T”, where T is an object type or void, “pointer to cv12 void”, where cv12 is the union of cv1 and cv2;
- (4.4) — if T<sub>1</sub> or T<sub>2</sub> is “pointer to noexcept function” and the other type is “pointer to function”, where the function types are otherwise the same, “pointer to function”;
- (4.5) — if T<sub>1</sub> is “pointer to cv1 C<sub>1</sub>” and T<sub>2</sub> is “pointer to cv2 C<sub>2</sub>”, where C<sub>1</sub> is reference-related to C<sub>2</sub> or C<sub>2</sub> is reference-related to C<sub>1</sub> (??), the cv-combined type of T<sub>1</sub> and T<sub>2</sub> or the cv-combined type of T<sub>2</sub> and T<sub>1</sub>, respectively;
- (4.6) — if T<sub>1</sub> is “pointer to member of C<sub>1</sub> of type cv1 U<sub>1</sub>” and T<sub>2</sub> is “pointer to member of C<sub>2</sub> of type cv2 U<sub>2</sub>” where C<sub>1</sub> is reference-related to C<sub>2</sub> or C<sub>2</sub> is reference-related to C<sub>1</sub> (??), the cv-combined type of T<sub>2</sub> and T<sub>1</sub> or the cv-combined type of T<sub>1</sub> and T<sub>2</sub>, respectively;
- (4.7) — if T<sub>1</sub> and T<sub>2</sub> are similar types (??), the cv-combined type of T<sub>1</sub> and T<sub>2</sub>;
- (4.8) — otherwise, a program that necessitates the determination of a composite pointer type is ill-formed.

[*Example*:

```
typedef void *p;
typedef const int *q;
typedef int **pi;
typedef const int **pci;
```

The composite pointer type of p and q is “pointer to const void”; the composite pointer type of pi and pci is “pointer to const pointer to const int”. — *end example*]

### 8.2.3 Context dependence

[expr.context]

- <sup>1</sup> In some contexts, *unevaluated operands* appear (??, ??, ??, ??, ??, ??). An unevaluated operand is not evaluated. [*Note*: In an unevaluated operand, a non-static class member may be named (??) and naming of objects or functions does not, by itself, require that a definition be provided (??). An unevaluated operand is considered a full-expression (??). — *end note*]
- <sup>2</sup> In some contexts, an expression only appears for its side effects. Such an expression is called a *discarded-value expression*. The array-to-pointer (??) and function-to-pointer (??) standard conversions are not applied. The lvalue-to-rvalue conversion (??) is applied if and only if the expression is a glvalue of volatile-qualified type and it is one of the following:

- (2.1) — (*expression*), where *expression* is one of these expressions,
- (2.2) — *id-expression* (??),
- (2.3) — subscripting (??),
- (2.4) — class member access (??),
- (2.5) — indirection (??),
- (2.6) — pointer-to-member operation (??),
- (2.7) — conditional expression (??) where both the second and the third operands are one of these expressions, or
- (2.8) — comma expression (??) where the right operand is one of these expressions.

[*Note*: Using an overloaded operator causes a function call; the above covers only operators with built-in meaning. — *end note*] If the (possibly converted) expression is a prvalue, the temporary materialization conversion (??) is applied. [*Note*: If the expression is an lvalue of class type, it must have a volatile copy constructor to initialize the temporary object that is the result object of the lvalue-to-rvalue conversion. — *end note*] The glvalue expression is evaluated and its value is discarded.

### 8.3 Usual arithmetic conversions

[expr.arith.conv]

<sup>1</sup> Many binary operators that expect operands of arithmetic or enumeration type cause conversions and yield result types in a similar way. The purpose is to yield a common type, which is also the type of the result. This pattern is called the *usual arithmetic conversions*, which are defined as follows:

- (1.1) — If either operand is of scoped enumeration type (??), no conversions are performed; if the other operand does not have the same type, the expression is ill-formed.
- (1.2) — If either operand is of type `long double`, the other shall be converted to `long double`.
- (1.3) — Otherwise, if either operand is `double`, the other shall be converted to `double`.
- (1.4) — Otherwise, if either operand is `float`, the other shall be converted to `float`.
- (1.5) — Otherwise, the integral promotions (??) shall be performed on both operands.<sup>64</sup> Then the following rules shall be applied to the promoted operands:
  - (1.5.1) — If both operands have the same type, no further conversion is needed.
  - (1.5.2) — Otherwise, if both operands have signed integer types or both have unsigned integer types, the operand with the type of lesser integer conversion rank shall be converted to the type of the operand with greater rank.
  - (1.5.3) — Otherwise, if the operand that has unsigned integer type has rank greater than or equal to the rank of the type of the other operand, the operand with signed integer type shall be converted to the type of the operand with unsigned integer type.
  - (1.5.4) — Otherwise, if the type of the operand with signed integer type can represent all of the values of the type of the operand with unsigned integer type, the operand with unsigned integer type shall be converted to the type of the operand with signed integer type.
  - (1.5.5) — Otherwise, both operands shall be converted to the unsigned integer type corresponding to the type of the operand with signed integer type.

<sup>64)</sup> As a consequence, operands of type `bool`, `char16_t`, `char32_t`, `wchar_t`, or an enumerated type are converted to some integral type.

## 8.4 Primary expressions

[expr.prim]

*primary-expression:*

- literal*
- this*
- ( *expression* )
- id-expression*
- lambda-expression*
- fold-expression*
- requires-expression*

### 8.4.1 Literals

[expr.prim.literal]

- 1 A *literal* is a primary expression. Its type depends on its form (??). A string literal is an lvalue; all other literals are prvalues.

### 8.4.2 This

[expr.prim.this]

- 1 The keyword **this** names a pointer to the object for which a non-static member function (??) is invoked or a non-static data member's initializer (??) is evaluated.
- 2 If a declaration declares a member function or member function template of a class X, the expression **this** is a prvalue of type “pointer to cv-qualifier-seq X” between the optional cv-qualifier-seq and the end of the *function-definition*, *member-declarator*, or *declarator*. It shall not appear before the optional cv-qualifier-seq and it shall not appear within the declaration of a static member function (although its type and value category are defined within a static member function as they are within a non-static member function). [Note: This is because declaration matching does not occur until the complete declarator is known. —end note] [Note: In a *trailing-return-type*, the class being defined is not required to be complete for purposes of class member access (??). Class members declared later are not visible. [Example:

```
struct A {
    char g();
    template<class T> auto f(T t) -> decltype(t + g())
        { return t + g(); }
};

template auto A::f(int t) -> decltype(t + g());
```

— end example] — end note]

- 3 Otherwise, if a *member-declarator* declares a non-static data member (??) of a class X, the expression **this** is a prvalue of type “pointer to X” within the optional default member initializer (??). It shall not appear elsewhere in the *member-declarator*.
- 4 The expression **this** shall not appear in any other context. [Example:

```
class Outer {
    int a[sizeof(*this)];           // error: not inside a member function
    unsigned int sz = sizeof(*this); // OK: in default member initializer

    void f() {
        int b[sizeof(*this)];       // OK

        struct Inner {
            int c[sizeof(*this)];   // error: not inside a member function of Inner
        };
    };
};
```

```

    }
};

— end example]
```

### 8.4.3 Parentheses

[expr.prim.paren]

- <sup>1</sup> A parenthesized expression (E) is a primary expression whose type, value, and value category are identical to those of E. The parenthesized expression can be used in exactly the same contexts as those where E can be used, and with the same meaning, except as otherwise indicated.

### 8.4.4 Names

[expr.prim.id]

*id-expression:*

- unqualified-id*
- qualified-id*

- <sup>1</sup> An *id-expression* is a restricted form of a *primary-expression*. [Note: An *id-expression* can appear after . and -> operators (??). — end note]
- <sup>2</sup> An *id-expression* that denotes a non-static data member or non-static member function of a class can only be used:

- (2.1) — as part of a class member access (??) in which the object expression refers to the member's class<sup>65</sup> or a class derived from that class, or
  - (2.2) — to form a pointer to member (??), or
  - (2.3) — if that *id-expression* denotes a non-static data member and it appears in an unevaluated operand.
- [Example:

```

struct S {
    int m;
};

int i = sizeof(S::m);           // OK
int j = sizeof(S::m + 42);     // OK

— end example]
```

- <sup>3</sup> An *id-expression* that denotes the specialization of a concept (??) results in a prvalue of type `bool`. The expression is `true` if the concept's normalized *constraint-expression* (??) is satisfied (??) by the specified template arguments and `false` otherwise. [Example:

```

template<typename T> concept C = true;
static_assert(C<int>); // OK
```

— end example] [Note: A concept's constraints are also considered when using a template name (??) and during overload resolution (??), and they are compared during the the partial ordering of constraints (??). — end note]

- <sup>4</sup> A program that refers explicitly or implicitly to a function with a trailing *requires-clause* whose *constraint-expression* is not satisfied, other than to declare it, is ill-formed. [Example:

```

void f(int) requires false;

void g() {
    f(0);           // error: cannot call f
```

---

<sup>65</sup>) This also applies when the object expression is an implicit (`*this`) (??).

```

void (*p1)(int) = f;           // error: cannot take the address of f
decltype(f)* p2 = nullptr;    // error: the type decltype(f) is invalid
}

```

In each case, the constraints of `f` are not satisfied. In the declaration of `p2`, those constraints are required to be satisfied even though `f` is an unevaluated operand (??). — end example]

#### 8.4.4.1 Unqualified names

[expr.prim.id.unqual]

*unqualified-id:*

- identifier*
- operator-function-id*
- conversion-function-id*
- literal-operator-id*
- $\sim$  *class-name*
- $\sim$  *decltype-specifier*
- template-id*

- 1 An *identifier* is an *id-expression* provided it has been suitably declared (??). [Note: For *operator-function-ids*, see ??; for *conversion-function-ids*, see ??; for *literal-operator-ids*, see ??; for *template-ids*, see ??]. A *class-name* or *decltype-specifier* prefixed by  $\sim$  denotes a destructor; see ?? . Within the definition of a non-static member function, an *identifier* that names a non-static member is transformed to a class member access expression (??). — end note]
- 2 The result is the entity denoted by the identifier. If the entity is a local entity and naming it from outside of an unevaluated operand within the declarative region where the *unqualified-id* appears would result in some intervening *lambda-expression* capturing it by copy (??), the type of the expression is the type of a class member access expression (??) naming the non-static data member that would be declared for such a capture in the closure object of the innermost such intervening *lambda-expression*. [Note: If that *lambda-expression* is not declared `mutable`, the type of such an identifier will typically be `const` qualified. — end note] Otherwise, the type of the expression is the type of the result. [Note: The type will be adjusted as described in ?? if it is cv-qualified or is a reference type. — end note] The expression is an lvalue if the entity is a function, variable, or data member and a prvalue otherwise (??); it is a bit-field if the identifier designates a bit-field (??). [Example:

```

void f() {
    float x, &r = x;
    [=] {
        decltype(x) y1;           // y1 has type float
        decltype((x)) y2 = y1;    // y2 has type float const& because this lambda
                                   // is not mutable and x is an lvalue
        decltype(r) r1 = y1;      // r1 has type float&
        decltype((r)) r2 = y2;    // r2 has type float const&
    };
}

```

— end example]

#### 8.4.4.2 Qualified names

[expr.prim.id.qual]

*qualified-id:*

*nested-name-specifier template<sub>opt</sub> unqualified-id*

```

nested-name-specifier:
  :: 
  type-name :: 
  namespace-name :: 
  decltype-specifier :: 
  nested-name-specifier identifier :: 
  nested-name-specifier templateopt simple-template-id :: 

```

- <sup>1</sup> The type denoted by a *decltype-specifier* in a *nested-name-specifier* shall be a class or enumeration type.
- <sup>2</sup> A *nested-name-specifier* that denotes a class, optionally followed by the keyword **template** (??), and then followed by the name of a member of either that class (??) or one of its base classes (??), is a *qualified-id*; ?? describes name lookup for class members that appear in *qualified-ids*. The result is the member. The type of the result is the type of the member. The result is an lvalue if the member is a static member function or a data member and a prvalue otherwise. [ *Note*: A class member can be referred to using a *qualified-id* at any point in its potential scope (??). — *end note* ] Where *class-name* ::~ *class-name* is used, the two *class-names* shall refer to the same class; this notation names the destructor (??). The form ~ *decltype-specifier* also denotes the destructor, but it shall not be used as the *unqualified-id* in a *qualified-id*. [ *Note*: A *typedef-name* that names a class is a *class-name* (??). — *end note* ]
- <sup>3</sup> The *nested-name-specifier* :: names the global namespace. A *nested-name-specifier* that names a namespace (??), optionally followed by the keyword **template** (??), and then followed by the name of a member of that namespace (or the name of a member of a namespace made visible by a *using-directive*), is a *qualified-id*; ?? describes name lookup for namespace members that appear in *qualified-ids*. The result is the member. The type of the result is the type of the member. The result is an lvalue if the member is a function or a variable and a prvalue otherwise.
- <sup>4</sup> A *nested-name-specifier* that denotes an enumeration (??), followed by the name of an enumerator of that enumeration, is a *qualified-id* that refers to the enumerator. The result is the enumerator. The type of the result is the type of the enumeration. The result is a prvalue.
- <sup>5</sup> In a *qualified-id*, if the *unqualified-id* is a *conversion-function-id*, its *conversion-type-id* shall denote the same type in both the context in which the entire *qualified-id* occurs and in the context of the class denoted by the *nested-name-specifier*.

#### 8.4.5 Lambda expressions

[**expr.prim.lambda**]

```

lambda-expression:
  lambda-introducer compound-statement
  lambda-introducer lambda-declarator requires-clauseopt compound-statement
  lambda-introducer < template-parameter-list > requires-clauseopt compound-statement
  lambda-introducer < template-parameter-list > requires-clauseopt
  lambda-declarator requires-clauseopt compound-statement

lambda-introducer:
  [ lambda-captureopt ]

lambda-declarator:
  ( parameter-declaration-clause ) decl-specifier-seqopt
    noexcept-specifieropt attribute-specifier-seqopt trailing-return-typeopt

```

- <sup>1</sup> Lambda expressions provide a concise way to create simple function objects. [ *Example*:

```
#include <algorithm>
#include <cmath>
void abssort(float* x, unsigned N) {
    std::sort(x, x + N, [](float a, float b) { return std::abs(a) < std::abs(b); });
}
— end example]
```

- 2 A *lambda-expression* is a prvalue whose result object is called the *closure object*. [Note: A closure object behaves like a function object (??). — end note]
- 3 In the *decl-specifier-seq* of the *lambda-declarator*, each *decl-specifier* shall either be `mutable` or `constexpr`. [Note: The trailing *requires-clause* is described in ???. — end note]
- 4 If a *lambda-expression* does not include a *lambda-declarator*, it is as if the *lambda-declarator* were (). The lambda return type is `auto`, which is replaced by the type specified by the *trailing-return-type* if provided and/or deduced from `return` statements as described in ???. [Example:

```
auto x1 = [](int i){ return i; };           // OK: return type is int
auto x2 = []{ return { 1, 2 }; };           // error: deducing return type from braced-init-list
int j;
auto x3 = []()>auto&& { return j; }; // OK: return type is int&
— end example]
```

- 5 A lambda is a *generic lambda* if the `auto` *type-specifier* appears as one of the *decl-specifiers* in the *decl-specifier-seq* of a *parameter-declaration* of the *lambda-expression*, or if the lambda has a *template-parameter-list*. [Example:

```
int i = [](int i, auto a) { return i; }(3, 4);           // OK: a generic lambda
int j = []<class T>(T t, int i) { return i; }(3, 4); // OK: a generic lambda
— end example]
```

#### 8.4.5.1 Closure types

[expr.prim.lambda.closure]

- 1 The type of a *lambda-expression* (which is also the type of the closure object) is a unique, unnamed non-union class type, called the *closure type*, whose properties are described below.
- 2 The closure type is declared in the smallest block scope, class scope, or namespace scope that contains the corresponding *lambda-expression*. [Note: This determines the set of namespaces and classes associated with the closure type (??). The parameter types of a *lambda-declarator* do not affect these associated namespaces and classes. — end note] The closure type is not an aggregate type (??). An implementation may define the closure type differently from what is described below provided this does not alter the observable behavior of the program other than by changing:

- (2.1) — the size and/or alignment of the closure type,
- (2.2) — whether the closure type is trivially copyable (??), or
- (2.3) — whether the closure type is a standard-layout class (??).

An implementation shall not add members of rvalue reference type to the closure type.

- 3 The closure type for a non-generic *lambda-expression* has a public inline function call operator (??) whose parameters and return type are described by the *lambda-expression's parameter-declaration-clause* and *trailing-return-type* respectively. For a generic lambda, the closure type has a public inline function call operator member template (??) whose *template-parameter-list* consists of the specified *template-parameter-list*,

if any, to which is appended one invented type *template-parameter* for each occurrence of `auto` in the lambda's *parameter-declaration-clause*, in order of appearance. The invented type *template-parameter* is a parameter pack if the corresponding *parameter-declaration* declares a function parameter pack (??). The return type and function parameters of the function call operator template are derived from the *lambda-expression's trailing-return-type* and *parameter-declaration-clause* by replacing each occurrence of `auto` in the *decl-specifiers* of the *parameter-declaration-clause* with the name of the corresponding invented *template-parameter*. The *requires-clause* of the function call operator template is the *requires-clause* immediately following `< template-parameter-list >`, if any. The trailing *requires-clause* of the function call operator or operator template is the *requires-clause* following the *lambda-declarator*, if any. [ *Example*:

```
auto glambda = [](auto a, auto&& b) { return a < b; };
bool b = glambda(3, 3.14); // OK

auto vglambda = [](auto printer) {
    return [=](auto&& ... ts) { // OK: ts is a function parameter pack
        printer(std::forward<decltype(ts)>(ts)...);

        return [=]() {
            printer(ts ...);
        };
    };
}
auto p = vglambda( [](auto v1, auto v2, auto v3)
    { std::cout << v1 << v2 << v3; } );
auto q = p(1, 'a', 3.14); // OK: outputs 1a3.14
q(); // OK: outputs 1a3.14

— end example ]
```

- <sup>4</sup> The function call operator or operator template is declared `const` (??) if and only if the *lambda-expression's parameter-declaration-clause* is not followed by `mutable`. It is neither virtual nor declared `volatile`. Any *noexcept-specifier* specified on a *lambda-expression* applies to the corresponding function call operator or operator template. An *attribute-specifier-seq* in a *lambda-declarator* appertains to the type of the corresponding function call operator or operator template. The function call operator or any given operator template specialization is a `constexpr` function if either the corresponding *lambda-expression's parameter-declaration-clause* is followed by `constexpr`, or it satisfies the requirements for a `constexpr` function (??). [ *Note*: Names referenced in the *lambda-declarator* are looked up in the context in which the *lambda-expression* appears.

— end note] [ *Example*:

```
auto ID = [](auto a) { return a; };
static_assert(ID(3) == 3); // OK

struct NonLiteral {
    NonLiteral(int n) : n(n) { }
    int n;
};
static_assert(ID(NonLiteral{3}).n == 3); // ill-formed

— end example ]
```

- <sup>5</sup> [ *Example*:

```
auto monoid = [](auto v) { return [=] { return v; }; };
```

```

auto add = [](auto m1) constexpr {
    auto ret = m1();
    return [=](auto m2) mutable {
        auto m1val = m1();
        auto plus = [=](auto m2val) mutable constexpr
            { return m1val += m2val; };
        ret = plus(m2());
        return monoid(ret);
    };
};

constexpr auto zero = monoid(0);
constexpr auto one = monoid(1);
static_assert(add(one)(zero)() == one()); // OK

// Since two below is not declared constexpr, an evaluation of its constexpr member function call operator
// cannot perform an lvalue-to-rvalue conversion on one of its subobjects (that represents its capture)
// in a constant expression.

auto two = monoid(2);
assert(two() == 2); // OK, not a constant expression.
static_assert(add(one)(one)() == two()); // ill-formed: two() is not a constant expression
static_assert(add(one)(one)() == monoid(2)()); // OK

— end example]

```

- <sup>6</sup> The function call operator or operator template may be constrained (??) by a *constrained-parameter* (??), a *requires-clause* (??), or a trailing *requires-clause* (??). [Example:

```

template <typename T> concept C1 = /* ... */;
template <std::size_t N> concept C2 = /* ... */;
template <typename A, typename B> concept C3 = /* ... */;

auto f = []<typename T1, C1 T2> requires C2<sizeof(T1) + sizeof(T2)>
    (T1 a1, T1 b1, T2 a2, auto a3, auto a4) requires C3<decltype(a4), T2> {
    // T2 is a constrained parameter,
    // T1 and T2 are constrained by a requires-clause, and
    // T2 and the type of a4 are constrained by a trailing requires-clause.
};

— end example]

```

- <sup>7</sup> The closure type for a non-generic *lambda-expression* with no *lambda-capture* whose constraints (if any) are satisfied has a conversion function to pointer to function with C++ language linkage (??) having the same parameter and return types as the closure type's function call operator. The conversion is to “pointer to *noexcept* function” if the function call operator has a non-throwing exception specification. The value returned by this conversion function is the address of a function F that, when invoked, has the same effect as invoking the closure type's function call operator. F is a `constexpr` function if the function call operator is a `constexpr` function. For a generic lambda with no *lambda-capture*, the closure type has a conversion function template to pointer to function. The conversion function template has the same invented template parameter list, and the pointer to function has the same parameter types, as the function call operator template. The return type of the pointer to function shall behave as if it were a *decltype-specifier* denoting the return type of the corresponding function call operator template specialization.

- <sup>8</sup> [Note: If the generic lambda has no *trailing-return-type* or the *trailing-return-type* contains a placeholder type, return type deduction of the corresponding function call operator template specialization has to be done. The corresponding specialization is that instantiation of the function call operator template with the same template arguments as those deduced for the conversion function template. Consider the following:

```
auto glambda = [](auto a) { return a; };
int (*fp)(int) = glambda;
```

The behavior of the conversion function of `glambda` above is like that of the following conversion function:

```
struct Closure {
    template<class T> auto operator()(T t) const { ... }
    template<class T> static auto lambda_call_operator_invoker(T a) {
        // forwards execution to operator()(a) and therefore has
        // the same return type deduced
        ...
    }
    template<class T> using fptr_t =
        decltype(lambda_call_operator_invoker(declval<T>()));
    template<class T> operator fptr_t<T>() const
        { return &lambda_call_operator_invoker; }
};
```

— end note]

[Example:

```
void f1(int (*)(int)) { }
void f2(char (*)(int)) { }

void g(int (*)(int)) { } // #1
void g(char (*)(char)) { } // #2

void h(int (*)(int)) { } // #3
void h(char (*)(int)) { } // #4

auto glambda = [](auto a) { return a; };
f1(glambda); // OK
f2(glambda); // error: ID is not convertible
g(glambda); // error: ambiguous
h(glambda); // OK: calls #3 since it is convertible from ID
int& (*fpi)(int*) = [](auto* a) -> auto& { return *a; }; // OK
```

— end example]

- <sup>9</sup> The value returned by any given specialization of this conversion function template is the address of a function `F` that, when invoked, has the same effect as invoking the generic lambda's corresponding function call operator template specialization. `F` is a `constexpr` function if the corresponding specialization is a `constexpr` function. [Note: This will result in the implicit instantiation of the generic lambda's body. The instantiated generic lambda's return type and parameter types shall match the return type and parameter types of the pointer to function. — end note] [Example:

```
auto GL = [](auto a) { std::cout << a; return a; };
int (*GL_int)(int) = GL; // OK: through conversion function template
```

```
GL_int(3); // OK: same as GL(3)
— end example]
```

- <sup>10</sup> The conversion function or conversion function template is public, constexpr, non-virtual, non-explicit, const, and has a non-throwing exception specification (??). [Example:

```
auto Fwd = [](int (*fp)(int), auto a) { return fp(a); };
auto C = [](auto a) { return a; };
```

```
static_assert(Fwd(C,3) == 3); // OK
```

// No specialization of the function call operator template can be constexpr (due to the local static).

```
auto NC = [](auto a) { static int s; return a; };
static_assert(Fwd(NC,3) == 3); // ill-formed
```

— end example]

- <sup>11</sup> The *lambda-expression*'s *compound-statement* yields the *function-body* (??) of the function call operator, but for purposes of name lookup (??), determining the type and value of `this` (??) and transforming *id-expressions* referring to non-static class members into class member access expressions using `(*this)` (??), the *compound-statement* is considered in the context of the *lambda-expression*. [Example:

```
struct S1 {
    int x, y;
    int operator()(int);
    void f() {
        [=] ()->int {
            return operator()(this->x + y); // equivalent to S1::operator()(this->x + (*this).y)
                                            // this has type S1*
        };
    }
};
```

— end example] Further, a variable `__func__` is implicitly defined at the beginning of the *compound-statement* of the *lambda-expression*, with semantics as described in ??.

- <sup>12</sup> The closure type associated with a *lambda-expression* has no default constructor if the *lambda-expression* has a *lambda-capture* and a defaulted default constructor otherwise. It has a defaulted copy constructor and a defaulted move constructor (??). It has a deleted copy assignment operator if the *lambda-expression* has a *lambda-capture* and defaulted copy and move assignment operators otherwise. [Note: These special member functions are implicitly defined as usual, and might therefore be defined as deleted. — end note]

- <sup>13</sup> The closure type associated with a *lambda-expression* has an implicitly-declared destructor (??).

- <sup>14</sup> A member of a closure type shall not be explicitly instantiated (??), explicitly specialized (??), or named in a friend declaration (??).

#### 8.4.5.2 Captures

[expr.prim.lambda.capture]

*lambda-capture*:  
*capture-default*  
*capture-list*  
*capture-default* , *capture-list*

```

capture-default:
  &
  =
capture-list:
  capture ...opt
  capture-list , capture ...opt
capture:
  simple-capture
  init-capture
simple-capture:
  identifier
  & identifier
  this
  * this
init-capture:
  identifier initializer
  & identifier initializer

```

- <sup>1</sup> The body of a *lambda-expression* may refer to variables with automatic storage duration and the `*this` object (if any) of enclosing block scopes by capturing those entities, as described below.
- <sup>2</sup> If a *lambda-capture* includes a *capture-default* that is `&`, no identifier in a *simple-capture* of that *lambda-capture* shall be preceded by `&`. If a *lambda-capture* includes a *capture-default* that is `=`, each *simple-capture* of that *lambda-capture* shall be of the form “`& identifier`”, “`this`”, or “`* this`”. [Note: The form `[&,this]` is redundant but accepted for compatibility with ISO C++ 2014. —end note] Ignoring appearances in *initializers* of *init-captures*, an identifier or `this` shall not appear more than once in a *lambda-capture*.
- [Example:

```

struct S2 { void f(int i); };
void S2::f(int i) {
  [&, i]{ };           // OK
  [&, this, i]{ };    // OK, equivalent to [&, i]
  [&, &i]{ };         // error: i preceded by & when & is the default
  [=, *this]{ };      // OK
  [=, this]{ };       // OK, equivalent to [=]
  [i, i]{ };          // error: i repeated
  [this, *this]{ };   // error: this appears twice
}

```

— end example ]

- <sup>3</sup> A *lambda-expression* is a *local lambda expression* if its innermost enclosing scope is a block scope (??), or if it appears within a default member initializer and its innermost enclosing scope is the corresponding class scope (??); any other *lambda-expression* shall not have a *capture-default* or *simple-capture* in its *lambda-introducer*.
- <sup>4</sup> The *identifier* in a *simple-capture* is looked up using the usual rules for unqualified name lookup (??); each such lookup shall find a local entity. The *simple-captures* `this` and `* this` denote the local entity `*this`. An entity that is designated by a *simple-capture* is said to be *explicitly captured*.
- <sup>5</sup> If an *identifier* in a *simple-capture* appears as the *declarator-id* of a parameter of the *lambda-declarator*'s *parameter-declaration-clause*, the program is ill-formed. [Example:

```

void f() {
    int x = 0;
    auto g = [x](int x) { return 0; }      // error: parameter and simple-capture have the same name
}

— end example]

```

- 6 An *init-capture* behaves as if it declares and explicitly captures a variable of the form “`auto init-capture` ;” whose declarative region is the *lambda-expression’s compound-statement*, except that:

- (6.1) — if the capture is by copy (see below), the non-static data member declared for the capture and the variable are treated as two different ways of referring to the same object, which has the lifetime of the non-static data member, and no additional copy and destruction is performed, and
- (6.2) — if the capture is by reference, the variable’s lifetime ends when the closure object’s lifetime ends.

[*Note*: This enables an *init-capture* like “`x = std::move(x)`”; the second “`x`” must bind to a declaration in the surrounding context. — end note] [*Example*:

```

int x = 4;
auto y = [&r = x, x = x+1]()>int {
    r += 2;
    return x+2;
}(); // Updates ::x to 6, and initializes y to 7.

```

`auto z = [a = 42](int a) { return 1; } // error: parameter and local variable have the same name`

— end example]

- 7 For the purposes of lambda capture, an expression potentially references local entities as follows:

- (7.1) — An *id-expression* that names a local entity potentially references that entity; an *id-expression* that names one or more non-static class members and does not form a pointer to member (??) potentially references `*this`. [*Note*: This occurs even if overload resolution selects a static member function for the *id-expression*. — end note]
- (7.2) — A `this` expression potentially references `*this`.
- (7.3) — A *lambda-expression* potentially references the local entities named by its *simple-captures*.

If an expression potentially references a local entity within a declarative region in which it is odr-usable, and the expression would be potentially evaluated if the effect of any enclosing `typeid` expressions (??) were ignored, the entity is said to be *implicitly captured* by each intervening *lambda-expression* with an associated *capture-default* that does not explicitly capture it. [*Example*:

```

void f(int, const int (&)[2] = {});           // #1
void f(const int&, const int (&)[1]);         // #2
void test() {
    const int x = 17;
    auto g = [](auto a) {
        f(x);                                // OK: calls #1, does not capture x
    };

    auto g1 = [=](auto a) {
        f(x);                                // OK: calls #1, captures x
    };
}

```

```

auto g2 = [=](auto a) {
    int selector[sizeof(a) == 1 ? 1 : 2]{};
    f(x, selector);           // OK: captures x, might call #1 or #2
};

auto g3 = [=](auto a) {
    typeid(a + x);          // captures x regardless of whether a + x is an unevaluated operand
};
}

```

Within g1, an implementation might optimize away the capture of x as it is not odr-used. — *end example*

[*Note*: The set of captured entities is determined syntactically, and entities might be implicitly captured even if the expression denoting a local entity is within a discarded statement (??). [*Example*:

```

template<bool B>
void f(int n) {
    [=](auto a) {
        if constexpr (B && sizeof(a) > 4) {
            (void)n;           // captures n regardless of the value of B and sizeof(int)
        }
    }(0);
}

```

— *end example*] — *end note*]

- <sup>8</sup> An entity is *captured* if it is captured explicitly or implicitly. An entity captured by a *lambda-expression* is odr-used (??) in the scope containing the *lambda-expression*. If a *lambda-expression* explicitly captures an entity that is not odr-usable or captures a structured binding (explicitly or implicitly), the program is ill-formed. [*Example*:

```

void f1(int i) {
    int const N = 20;
    auto m1 = [=]{
        int const M = 30;
        auto m2 = [i]{
            int x[N][M];           // OK: N and M are not odr-used
            x[0][0] = i;           // OK: i is explicitly captured by m2 and implicitly captured by m1
        };
    };
    struct s1 {
        int f;
        void work(int n) {
            int m = n*n;
            int j = 40;
            auto m3 = [this,m] {
                auto m4 = [&,j] {           // error: j not odr-usable due to intervening lambda m3
                    int x = n;             // error: n is odr-used but not odr-usable due to intervening lambda m3
                    x += m;               // OK: m implicitly captured by m4 and explicitly captured by m3
                    x += i;               // error: i is odr-used but not odr-usable
                    // due to intervening function and class scopes
                    x += f;               // OK: this captured implicitly by m4 and explicitly by m3
                };
            };
        };
    };
}

```

```

    };
}
};

struct s2 {
    double ohseven = .007;
    auto f() {
        return [this] {
            return [*this] {
                return ohseven;           // OK
            }
        }();
    }
    auto g() {
        return [] {
            return [*this] { };      // error: *this not captured by outer lambda-expression
        }();
    }
};

— end example]

```

- <sup>9</sup> A *lambda-expression* appearing in a default argument shall not implicitly or explicitly capture any entity.  
[*Example*:

```

void f2() {
    int i = 1;
    void g1(int = ([i]{ return i; })());           // ill-formed
    void g2(int = ([i]{ return 0; })());           // ill-formed
    void g3(int = ([=]{ return i; })());           // ill-formed
    void g4(int = ([=]{ return 0; })());           // OK
    void g5(int = ([]{ return sizeof i; })());     // OK
}

```

— end example]

- <sup>10</sup> An entity is *captured by copy* if

- (10.1) — it is implicitly captured, the *capture-default* is `=`, and the captured entity is not `*this`, or
- (10.2) — it is explicitly captured with a capture that is not of the form `this`, `& identifier`, or `& identifier initializer`.

For each entity captured by copy, an unnamed non-static data member is declared in the closure type. The declaration order of these members is unspecified. The type of such a data member is the referenced type if the entity is a reference to an object, an lvalue reference to the referenced function type if the entity is a reference to a function, or the type of the corresponding captured entity otherwise. A member of an anonymous union shall not be captured by copy.

- <sup>11</sup> Every *id-expression* within the *compound-statement* of a *lambda-expression* that is an odr-use (??) of an entity captured by copy is transformed into an access to the corresponding unnamed data member of the closure type. [*Note*: An *id-expression* that is not an odr-use refers to the original entity, never to a member of the closure type. However, such an *id-expression* can still cause the implicit capture of the entity.] — end

*note]* If `*this` is captured by copy, each expression that odr-uses `*this` is transformed to instead refer to the corresponding unnamed data member of the closure type. [ *Example*:

```
void f(const int*);  
void g() {  
    const int N = 10;  
    [=] {  
        int arr[N];      // OK: not an odr-use, refers to automatic variable  
        f(&N);          // OK: causes N to be captured; &N points to  
                        // the corresponding member of the closure type  
    };  
}
```

— *end example* ]

- 12 An entity is *captured by reference* if it is implicitly or explicitly captured but not captured by copy. It is unspecified whether additional unnamed non-static data members are declared in the closure type for entities captured by reference. If declared, such non-static data members shall be of literal type. [ *Example*:

```
// The inner closure type must be a literal type regardless of how reference captures are represented.  
static_assert([](int n) { return [&n] { return ++n; }(); }(3) == 4);
```

— *end example*] A bit-field or a member of an anonymous union shall not be captured by reference.

- 13 An *id-expression* within the *compound-statement* of a *lambda-expression* that is an odr-use of a reference captured by reference refers to the entity to which the captured reference is bound and not to the captured reference. [ *Note*: The validity of such captures is determined by the lifetime of the object to which the reference refers, not by the lifetime of the reference itself. — *end note*] [ *Example*:

```
auto h(int &r) {  
    return [&] {  
        ++r;           // Valid after h returns if the lifetime of the  
                        // object to which r is bound has not ended  
    };  
}
```

— *end example* ]

- 14 If a *lambda-expression* `m2` captures an entity and that entity is captured by an immediately enclosing *lambda-expression* `m1`, then `m2`'s capture is transformed as follows:

- (14.1) — if `m1` captures the entity by copy, `m2` captures the corresponding non-static data member of `m1`'s closure type;
- (14.2) — if `m1` captures the entity by reference, `m2` captures the same entity captured by `m1`.

[ *Example*: The nested lambda expressions and invocations below will output 123234.

```
int a = 1, b = 1, c = 1;  
auto m1 = [a, &b, &c]() mutable {  
    auto m2 = [a, b, &c]() mutable {  
        std::cout << a << b << c;  
        a = 4; b = 4; c = 4;  
    };  
    a = 3; b = 3; c = 3;  
    m2();  
};
```

```
a = 2; b = 2; c = 2;
m1();
std::cout << a << b << c;

— end example]
```

- <sup>15</sup> When the *lambda-expression* is evaluated, the entities that are captured by copy are used to direct-initialize each corresponding non-static data member of the resulting closure object, and the non-static data members corresponding to the *init-captures* are initialized as indicated by the corresponding *initializer* (which may be copy- or direct-initialization). (For array members, the array elements are direct-initialized in increasing subscript order.) These initializations are performed in the (unspecified) order in which the non-static data members are declared. [Note: This ensures that the destructions will occur in the reverse order of the constructions. — end note]
- <sup>16</sup> [Note: If a non-reference entity is implicitly or explicitly captured by reference, invoking the function call operator of the corresponding *lambda-expression* after the lifetime of the entity has ended is likely to result in undefined behavior. — end note]
- <sup>17</sup> A *simple-capture* followed by an ellipsis is a pack expansion (??). An *init-capture* followed by an ellipsis is ill-formed. [Example:

```
template<class... Args>
void f(Args... args) {
    auto lm = [&, args...] { return g(args...); };
    lm();
}
```

— end example]

#### 8.4.6 Fold expressions

[expr.prim.fold]

- <sup>1</sup> A fold expression performs a fold of a template parameter pack (??) over a binary operator.

*fold-expression:*

- ( *cast-expression fold-operator ...* )
- ( ... *fold-operator cast-expression* )
- ( *cast-expression fold-operator ... fold-operator cast-expression* )

*fold-operator:* one of

+	-	*	/	%	^	&		<<	>>
+ =	- =	* =	/ =	% =	^ =	& =	=	<< =	>> =
= =	!=	<	>	<=	>=	&&		,	.*
->*									

- <sup>2</sup> An expression of the form (... *op e*) where *op* is a *fold-operator* is called a *unary left fold*. An expression of the form (*e op ...*) where *op* is a *fold-operator* is called a *unary right fold*. Unary left folds and unary right folds are collectively called *unary folds*. In a unary fold, the *cast-expression* shall contain an unexpanded parameter pack (??).
- <sup>3</sup> An expression of the form (*e1 op1 ... op2 e2*) where *op1* and *op2* are *fold-operators* is called a *binary fold*. In a binary fold, *op1* and *op2* shall be the same *fold-operator*, and either *e1* shall contain an unexpanded parameter pack or *e2* shall contain an unexpanded parameter pack, but not both. If *e2* contains an unexpanded parameter pack, the expression is called a *binary left fold*. If *e1* contains an unexpanded parameter pack, the expression is called a *binary right fold*. [Example:

```

template<typename ...Args>
bool f(Args ...args) {
    return (true && ... && args); // OK
}

template<typename ...Args>
bool f(Args ...args) {
    return (args + ... + args); // error: both operands contain unexpanded parameter packs
}

— end example]

```

#### 8.4.7 Requires expressions

[expr.prim.req]

- <sup>1</sup> A *requires-expression* provides a concise way to express requirements on template arguments that can be checked by name lookup (??) or by checking properties of types and expressions.

```

requires-expression:
    requires requirement-parameter-listopt requirement-body

requirement-parameter-list:
    ( parameter-declaration-clauseopt )

requirement-body:
    { requirement-seq }

requirement-seq:
    requirement
    requirement-seq requirement

requirement:
    simple-requirement
    type-requirement
    compound-requirement
    nested-requirement

```

- <sup>2</sup> A *requires-expression* is a prvalue of type `bool` whose value is described below. Expressions appearing within a *requirement-body* are unevaluated operands (??).
- <sup>3</sup> [ *Example*: A common use of *requires-expressions* is to define requirements in concepts such as the one below:

```

template<typename T>
concept R = requires (T i) {
    typename T::type;
    {*i} -> const typename T::type&;
};

```

A *requires-expression* can also be used in a *requires-clause* (??) as a way of writing ad hoc constraints on template arguments such as the one below:

```

template<typename T>
requires requires (T x) { x + x; }
T add(T a, T b) { return a + b; }

```

The first `requires` introduces the *requires-clause*, and the second introduces the *requires-expression*. — end example]

- <sup>4</sup> A *requires-expression* may introduce local parameters using a *parameter-declaration-clause* (??). A local parameter of a *requires-expression* shall not have a default argument. Each name introduced by a local parameter is in scope from the point of its declaration until the closing brace of the *requirement-body*. These parameters have no linkage, storage, or lifetime; they are only used as notation for the purpose of defining *requirements*. The *parameter-declaration-clause* of a *requirement-parameter-list* shall not terminate with an ellipsis. [Example:

```
template<typename T>
concept C = requires(T t, ...) {      // error: terminates with an ellipsis
    t;
};

— end example]
```

- <sup>5</sup> The *requirement-body* contains a sequence of *requirements*. These *requirements* may refer to local parameters, template parameters, and any other declarations visible from the enclosing context.
- <sup>6</sup> The substitution of template arguments into a *requires-expression* may result in the formation of invalid types or expressions in its requirements or the violation of the semantic constraints of those requirements. In such cases, the *requires-expression* evaluates to **false**; it does not cause the program to be ill-formed. The substitution and semantic constraint checking proceeds in lexical order and stops when a condition that determines the result of the *requires-expression* is encountered. If substitution (if any) and semantic constraint checking succeed, the *requires-expression* evaluates to **true**. [Note: If a *requires-expression* contains invalid types or expressions in its requirements, and it does not appear within the declaration of a templated entity, then the program is ill-formed. — end note] If the substitution of template arguments into a *requirement* would always result in a substitution failure, the program is ill-formed; no diagnostic required. [Example:

```
template<typename T> concept C =
    requires {
        new int[-(int)sizeof(T)]; // ill-formed, no diagnostic required
    };

— end example]
```

#### 8.4.7.1 Simple requirements

[expr.prim.req.simple]

*simple-requirement:*

*expression* ;

- <sup>1</sup> A *simple-requirement* asserts the validity of an *expression*. [Note: The enclosing *requires-expression* will evaluate to **false** if substitution of template arguments into the *expression* fails. The *expression* is an unevaluated operand (??). — end note] [Example:

```
template<typename T> concept C =
    requires (T a, T b) {
        a + b; // C<T> is true if a + b is a valid expression
    };

— end example]
```

#### 8.4.7.2 Type requirements

[expr.prim.req.type]

*type-requirement:*

*typename nested-name-specifier<sub>opt</sub> type-name* ;

- <sup>1</sup> A *type-requirement* asserts the validity of a type. [Note: The enclosing *requires-expression* will evaluate to **false** if substitution of template arguments fails. — end note] [Example:

```

template<typename T, typename T::type = 0> struct S;
template<typename T> using Ref = T&;

template<typename T> concept C = requires {
    typename T::inner;      // required nested member name
    typename S<T>;         // required class template specialization
    typename Ref<T>;       // required alias template substitution, fails if T is void
};

— end example]

```

- 2 A *type-requirement* that names a class template specialization does not require that type to be complete (??).

#### 8.4.7.3 Compound requirements

[expr.prim.req.compound]

*compound-requirement*:

{ *expression* } noexcept<sub>opt</sub> *return-type-requirement*<sub>opt</sub> ;

*return-type-requirement*:

*trailing-return-type*

→ *cv-qualifier-seq*<sub>opt</sub> *constrained-parameter* *cv-qualifier-seq*<sub>opt</sub> *abstract-declarator*<sub>opt</sub>

- 1 A *compound-requirement* asserts properties of the *expression* E. Substitution of template arguments (if any) and verification of semantic properties proceed in the following order:

- (1.1) — Substitution of template arguments (if any) into the *expression* is performed.
- (1.2) — If the *noexcept* specifier is present, E shall not be a potentially-throwing expression (??).
- (1.3) — If the *return-type-requirement* is present, then:
  - (1.3.1) — Substitution of template arguments (if any) into the *return-type-requirement* is performed.
  - (1.3.2) — If the *return-type-requirement* is a *trailing-return-type*, E is implicitly convertible to the type named by the *trailing-return-type*. If conversion fails, the enclosing *requires-expression* is **false**.
  - (1.3.3) — If the *return-type-requirement* starts with a *constrained-parameter* (??), the *expression* is deduced against an invented function template F using the rules in ???. F is a *void* function template with a single type template parameter T declared with the *constrained-parameter*. A *cv-qualifier-seq* cv is formed as the union of **const** and **volatile** specifiers around the *constrained-parameter*. F has a single parameter whose *type-specifier* is cv T followed by the *abstract-declarator*. If deduction fails, the enclosing *requires-expression* is **false**.

[*Example*:

```

template<typename T> concept C1 = requires(T x) {
    {x++};
};

```

The *compound-requirement* in C1 requires that x++ is a valid expression. It is equivalent to the *simple-requirement* x++;

```

template<typename T> concept C2 = requires(T x) {
    {*x} -> typename T::inner;
};

```

The *compound-requirement* in C2 requires that \*x is a valid expression, that **typename T::inner** is a valid type, and that \*x is implicitly convertible to **typename T::inner**.

```
template<typename T, typename U> concept C3 = requires (T t, U u) {
    t == u;
};

template<typename T> concept C4 = requires(T x) {
    {*x} -> C3<int> const&;
};
```

The *compound-requirement* requires that `*x` be deduced as an argument for the invented function:

```
template<C3<int> X> void f(X const&);
```

In this case, deduction only succeeds if an expression of the type deduced for `X` can be compared to an `int` with the `==` operator.

```
template<typename T> concept C5 =
    requires(T x) {
        {g(x)} noexcept;
    };
};
```

The *compound-requirement* in `C5` requires that `g(x)` is a valid expression and that `g(x)` is non-throwing.  
— end example ]

#### 8.4.7.4 Nested requirements

[expr.prim.req.nested]

*nested-requirement*:

```
    requires constraint-expression ;
```

- 1 A *nested-requirement* can be used to specify additional constraints in terms of local parameters. The *constraint-expression* shall be satisfied (??) by the substituted template arguments, if any. Substitution of template arguments into a *nested-requirement* does not result in substitution into the *constraint-expression* other than as specified in ???. [Example:

```
template<typename U> concept C = sizeof(U) == 1;
```

```
template<typename T> concept D = requires (T t) {
    requires C<decltype (+t)>;
};
```

`D<T>` is satisfied if `sizeof decltype (+t)) == 1` (??). — end example ]

- 2 A local parameter shall only appear as an unevaluated operand (??) within the *constraint-expression*. [Example:

```
template<typename T> concept C = requires (T a) {
    requires sizeof(a) == 4; // OK
    requires a == 0; // error: evaluation of a constraint variable
};
```

— end example ]

## 8.5 Compound expressions

[expr.compound]

### 8.5.1 Postfix expressions

[expr.post]

- 1 Postfix expressions group left-to-right.

```

postfix-expression:
  primary-expression
  postfix-expression [ expr-or-braced-init-list ]
  postfix-expression ( expression-listopt )
  simple-type-specifier ( expression-listopt )
  typename-specifier ( expression-listopt )
  simple-type-specifier braced-init-list
  typename-specifier braced-init-list
  postfix-expression . templateopt id-expression
  postfix-expression -> templateopt id-expression
  postfix-expression . pseudo-destructor-name
  postfix-expression -> pseudo-destructor-name
  postfix-expression ++
  postfix-expression --
  dynamic_cast < type-id > ( expression )
  static_cast < type-id > ( expression )
  reinterpret_cast < type-id > ( expression )
  const_cast < type-id > ( expression )
  typeid ( expression )
  typeid ( type-id )

expression-list:
  initializer-list

pseudo-destructor-name:
  nested-name-specifieropt type-name :: ~ type-name
  nested-name-specifier template simple-template-id :: ~ type-name
  ~ type-name
  ~ decltype-specifier

```

- <sup>2</sup> [Note: The > token following the *type-id* in a *dynamic\_cast*, *static\_cast*, *reinterpret\_cast*, or *const\_cast* may be the product of replacing a >> token by two consecutive > tokens (??). —end note]

### 8.5.1.1 Subscripting

[expr.sub]

- <sup>1</sup> A postfix expression followed by an expression in square brackets is a postfix expression. One of the expressions shall be a glvalue of type “array of T” or a prvalue of type “pointer to T” and the other shall be a prvalue of unscoped enumeration or integral type. The result is of type “T”. The type “T” shall be a completely-defined object type.<sup>66</sup> The expression E1 [E2] is identical (by definition) to \*((E1)+(E2)) [Note: see ?? and ?? for details of \* and + and ?? for details of arrays. —end note], except that in the case of an array operand, the result is an lvalue if that operand is an lvalue and an xvalue otherwise. The expression E1 is sequenced before the expression E2.
- <sup>2</sup> A *braced-init-list* shall not be used with the built-in subscript operator.

### 8.5.1.2 Function call

[expr.call]

- <sup>1</sup> A function call is a postfix expression followed by parentheses containing a possibly empty, comma-separated list of *initializer-clauses* which constitute the arguments to the function. The postfix expression shall have function type or function pointer type. For a call to a non-member function or to a static member function, the postfix expression shall be either an lvalue that refers to a function (in which case the function-to-pointer standard conversion (??) is suppressed on the postfix expression), or it shall have function pointer type.

<sup>66</sup>) This is true even if the subscript operator is used in the following common idiom: &x[0].

Calling a function through an expression whose function type is different from the function type of the called function's definition results in undefined behavior (??). For a call to a non-static member function, the postfix expression shall be an implicit (??, ??) or explicit class member access (??) whose *id-expression* is a function member name, or a pointer-to-member expression (??) selecting a function member; the call is as a member of the class object referred to by the object expression. In the case of an implicit class member access, the implied object is the one pointed to by `this`. [Note: A member function call of the form `f()` is interpreted as `(*this).f()` (see ??). —end note] If a function or member function name is used, the name can be overloaded (??), in which case the appropriate function shall be selected according to the rules in ?. If the selected function is non-virtual, or if the *id-expression* in the class member access expression is a *qualified-id*, that function is called. Otherwise, its final overrider (??) in the dynamic type of the object expression is called; such a call is referred to as a *virtual function call*. [Note: The dynamic type is the type of the object referred to by the current value of the object expression. ?? describes the behavior of virtual function calls when the object expression refers to an object under construction or destruction. —end note]

- 2 [Note: If a function or member function name is used, and name lookup (??) does not find a declaration of that name, the program is ill-formed. No function is implicitly declared by such a call. —end note]
- 3 If the *postfix-expression* designates a destructor (??), the type of the function call expression is `void`; otherwise, the type of the function call expression is the return type of the statically chosen function (i.e., ignoring the `virtual` keyword), even if the type of the function actually called is different. This return type shall be an object type, a reference type or *cv void*.
- 4 When a function is called, each parameter (??) shall be initialized (??, ??, ??) with its corresponding argument. If the function is a non-static member function, the `this` parameter of the function (??) shall be initialized with a pointer to the object of the call, converted as if by an explicit type conversion (??). [Note: There is no access or ambiguity checking on this conversion; the access checking and disambiguation are done as part of the (possibly implicit) class member access operator. See ??, ??, and ?. —end note] When a function is called, the parameters that have object type shall have completely-defined object type. [Note: this still allows a parameter to be a pointer or reference to an incomplete class type. However, it prevents a passed-by-value parameter to have an incomplete class type. —end note] It is implementation-defined whether the lifetime of a parameter ends when the function in which it is defined returns or at the end of the enclosing full-expression. The initialization and destruction of each parameter occurs within the context of the calling function. [Example: The access of the constructor, conversion functions or destructor is checked at the point of call in the calling function. If a constructor or destructor for a function parameter throws an exception, the search for a handler starts in the scope of the calling function; in particular, if the function called has a *function-try-block* (??) with a handler that could handle the exception, this handler is not considered. —end example]
- 5 The *postfix-expression* is sequenced before each *expression* in the *expression-list* and any default argument. The initialization of a parameter, including every associated value computation and side effect, is indeterminately sequenced with respect to that of any other parameter. [Note: All side effects of argument evaluations are sequenced before the function is entered (see ??). —end note] [Example:

```
void f() {
    std::string s = "but I have heard it works even if you don't believe in it";
    s.replace(0, 4, "").replace(s.find("even"), 4, "only").replace(s.find(" don't"), 6, "");
    assert(s == "I have heard it works only if you believe in it"); // OK
}
```

— end example] [Note: If an operator function is invoked using operator notation, argument evaluation is sequenced as specified for the built-in operator; see ??.

— end note] [Example:

```
struct S {
    S(int);
};

int operator<<(S, int);

int i, j;
int x = S(i=1) << (i=2);
int y = operator<<(S(j=1), j=2);
```

After performing the initializations, the value of `i` is 2 (see ??), but it is unspecified whether the value of `j` is 1 or 2.

— end example]

- <sup>6</sup> The result of a function call is the result of the operand of the evaluated `return` statement (??) in the called function (if any), except in a virtual function call if the return type of the final overrider is different from the return type of the statically chosen function, the value returned from the final overrider is converted to the return type of the statically chosen function.
- <sup>7</sup> [Note: A function can change the values of its non-const parameters, but these changes cannot affect the values of the arguments except where a parameter is of a reference type (??); if the reference is to a const-qualified type, `const_cast` is required to be used to cast away the constness in order to modify the argument's value. Where a parameter is of `const` reference type a temporary object is introduced if needed (??, ??, ??, ??, ??). In addition, it is possible to modify the values of non-constant objects through pointer parameters.
- end note]
- <sup>8</sup> A function can be declared to accept fewer arguments (by declaring default arguments (??)) or more arguments (by using the ellipsis, ..., or a function parameter pack (??)) than the number of parameters in the function definition (??). [Note: This implies that, except where the ellipsis (...) or a function parameter pack is used, a parameter is available for each argument.
- end note]
- <sup>9</sup> When there is no parameter for a given argument, the argument is passed in such a way that the receiving function can obtain the value of the argument by invoking `va_arg` (??). [Note: This paragraph does not apply to arguments passed to a function parameter pack. Function parameter packs are expanded during template instantiation (??), thus each such argument has a corresponding parameter when a function template specialization is actually called.
- end note]
- The lvalue-to-rvalue (??), array-to-pointer (??), and function-to-pointer (??) standard conversions are performed on the argument expression. An argument that has type `cv std::nullptr_t` is converted to type `void*` (??). After these conversions, if the argument does not have arithmetic, enumeration, pointer, pointer-to-member, or class type, the program is ill-formed. Passing a potentially-evaluated argument of class type (??) having a non-trivial copy constructor, a non-trivial move constructor, or a non-trivial destructor, with no corresponding parameter, is conditionally-supported with implementation-defined semantics. If the argument has integral or enumeration type that is subject to the integral promotions (??), or a floating-point type that is subject to the floating-point promotion (??), the value of the argument is converted to the promoted type before the call. These promotions are referred to as the *default argument promotions*.
- <sup>10</sup> Recursive calls are permitted, except to the `main` function (??).
- <sup>11</sup> A function call is an lvalue if the result type is an lvalue reference type or an rvalue reference to function type, an xvalue if the result type is an rvalue reference to object type, and a prvalue otherwise.

### 8.5.1.3 Explicit type conversion (functional notation)

[expr.type.conv]

- <sup>1</sup> A *simple-type-specifier* (??) or *typename-specifier* (??) followed by a parenthesized optional *expression-list* or by a *braced-init-list* (the initializer) constructs a value of the specified type given the initializer. If the type is a placeholder for a deduced class type, it is replaced by the return type of the function selected by overload resolution for class template deduction (??) for the remainder of this subclause.
- <sup>2</sup> If the initializer is a parenthesized single expression, the type conversion expression is equivalent to the corresponding cast expression (??). Otherwise, if the type is *cv void* and the initializer is (), the expression is a prvalue of the specified type that performs no initialization. Otherwise, the expression is a prvalue of the specified type whose result object is direct-initialized (??) with the initializer. For an expression of the form T(), T shall not be an array type.

### 8.5.1.4 Pseudo destructor call

[expr.pseudo]

- <sup>1</sup> The use of a *pseudo-destructor-name* after a dot . or arrow -> operator represents the destructor for the non-class type denoted by *type-name* or *decltype-specifier*. The result shall only be used as the operand for the function call operator (), and the result of such a call has type **void**. The only effect is the evaluation of the *postfix-expression* before the dot or arrow.
- <sup>2</sup> The left-hand side of the dot operator shall be of scalar type. The left-hand side of the arrow operator shall be of pointer to scalar type. This scalar type is the object type. The *cv-unqualified* versions of the object type and of the type designated by the *pseudo-destructor-name* shall be the same type. Furthermore, the two *type-names* in a *pseudo-destructor-name* of the form

*nested-name-specifier<sub>opt</sub>* *type-name* :: ~ *type-name*

shall designate the same scalar type (ignoring cv-qualification).

### 8.5.1.5 Class member access

[expr.ref]

- <sup>1</sup> A postfix expression followed by a dot . or an arrow ->, optionally followed by the keyword **template** (??), and then followed by an *id-expression*, is a postfix expression. The postfix expression before the dot or arrow is evaluated;<sup>67</sup> the result of that evaluation, together with the *id-expression*, determines the result of the entire postfix expression.
- <sup>2</sup> For the first option (dot) the first expression shall be a glvalue having class type. For the second option (arrow) the first expression shall be a prvalue having pointer to class type. In both cases, the class type shall be complete unless the class member access appears in the definition of that class. [ *Note*: If the class is incomplete, lookup in the complete class type is required to refer to the same declaration (??). — *end note* ] The expression E1->E2 is converted to the equivalent form (\*(*E1*)).*E2*; the remainder of ?? will address only the first option (dot).<sup>68</sup> In either case, the *id-expression* shall name a member of the class or of one of its base classes. [ *Note*: Because the name of a class is inserted in its class scope (??), the name of a class is also considered a nested member of that class. — *end note* ] [ *Note*: ?? describes how names are looked up after the . and -> operators. — *end note* ]
- <sup>3</sup> Abbreviating *postfix-expression.id-expression* as *E1.E2*, *E1* is called the *object expression*. If *E2* is a bit-field, *E1.E2* is a bit-field. The type and value category of *E1.E2* are determined as follows. In the remainder of ??, *cq* represents either **const** or the absence of **const** and *vq* represents either **volatile** or the absence of **volatile**. *cv* represents an arbitrary set of cv-qualifiers, as defined in ??.

<sup>67</sup>) If the class member access expression is evaluated, the subexpression evaluation happens even if the result is unnecessary to determine the value of the entire postfix expression, for example if the *id-expression* denotes a static member.

<sup>68</sup>) Note that (\*(*E1*)) is an lvalue.

<sup>4</sup> If E2 is declared to have type “reference to T”, then E1.E2 is an lvalue; the type of E1.E2 is T. Otherwise, one of the following rules applies.

- (4.1) — If E2 is a static data member and the type of E2 is T, then E1.E2 is an lvalue; the expression designates the named member of the class. The type of E1.E2 is T.
- (4.2) — If E2 is a non-static data member and the type of E1 is “cq1 vq1 X”, and the type of E2 is “cq2 vq2 T”, the expression designates the named member of the object designated by the first expression. If E1 is an lvalue, then E1.E2 is an lvalue; otherwise E1.E2 is an xvalue. Let the notation vq12 stand for the “union” of vq1 and vq2; that is, if vq1 or vq2 is volatile, then vq12 is volatile. Similarly, let the notation cq12 stand for the “union” of cq1 and cq2; that is, if cq1 or cq2 is const, then cq12 is const. If E2 is declared to be a mutable member, then the type of E1.E2 is “vq12 T”. If E2 is not declared to be a mutable member, then the type of E1.E2 is “cq12 vq12 T”.
- (4.3) — If E2 is a (possibly overloaded) member function, function overload resolution (??) is used to determine whether E1.E2 refers to a static or a non-static member function.
  - (4.3.1) — If it refers to a static member function and the type of E2 is “function of parameter-type-list returning T”, then E1.E2 is an lvalue; the expression designates the static member function. The type of E1.E2 is the same type as that of E2, namely “function of parameter-type-list returning T”.
  - (4.3.2) — Otherwise, if E1.E2 refers to a non-static member function and the type of E2 is “function of parameter-type-list cv ref-qualifier<sub>opt</sub> returning T”, then E1.E2 is a prvalue. The expression designates a non-static member function. The expression can be used only as the left-hand operand of a member function call (??). [Note: Any redundant set of parentheses surrounding the expression is ignored (??). — end note] The type of E1.E2 is “function of parameter-type-list cv returning T”.
- (4.4) — If E2 is a nested type, the expression E1.E2 is ill-formed.
- (4.5) — If E2 is a member enumerator and the type of E2 is T, the expression E1.E2 is a prvalue. The type of E1.E2 is T.

<sup>5</sup> If E2 is a non-static data member or a non-static member function, the program is ill-formed if the class of which E2 is directly a member is an ambiguous base (??) of the naming class (??) of E2. [Note: The program is also ill-formed if the naming class is an ambiguous base of the class type of the object expression; see ??.. — end note]

### 8.5.1.6 Increment and decrement

[expr.post.incr]

- <sup>1</sup> The value of a postfix ++ expression is the value of its operand. [Note: The value obtained is a copy of the original value — end note] The operand shall be a modifiable lvalue. The type of the operand shall be an arithmetic type other than cv bool, or a pointer to a complete object type. The value of the operand object is modified by adding 1 to it. The value computation of the ++ expression is sequenced before the modification of the operand object. With respect to an indeterminately-sequenced function call, the operation of postfix ++ is a single evaluation. [Note: Therefore, a function call shall not intervene between the lvalue-to-rvalue conversion and the side effect associated with any single postfix ++ operator. — end note] The result is a prvalue. The type of the result is the cv-unqualified version of the type of the operand. If the operand is a bit-field that cannot represent the incremented value, the resulting value of the bit-field is implementation-defined. See also ?? and ??.
- <sup>2</sup> The operand of postfix -- is decremented analogously to the postfix ++ operator. [Note: For prefix increment and decrement, see ??.. — end note]

### 8.5.1.7 Dynamic cast

[expr.dynamic.cast]

- <sup>1</sup> The result of the expression `dynamic_cast<T>(v)` is the result of converting the expression `v` to type `T`. `T` shall be a pointer or reference to a complete class type, or “pointer to `cv void`”. The `dynamic_cast` operator shall not cast away constness (??).
- <sup>2</sup> If `T` is a pointer type, `v` shall be a prvalue of a pointer to complete class type, and the result is a prvalue of type `T`. If `T` is an lvalue reference type, `v` shall be an lvalue of a complete class type, and the result is an lvalue of the type referred to by `T`. If `T` is an rvalue reference type, `v` shall be a glvalue having a complete class type, and the result is an xvalue of the type referred to by `T`.
- <sup>3</sup> If the type of `v` is the same as `T`, or it is the same as `T` except that the class object type in `T` is more cv-qualified than the class object type in `v`, the result is `v` (converted if necessary).
- <sup>4</sup> If the value of `v` is a null pointer value in the pointer case, the result is the null pointer value of type `T`.
- <sup>5</sup> If `T` is “pointer to `cv1 B`” and `v` has type “pointer to `cv2 D`” such that `B` is a base class of `D`, the result is a pointer to the unique `B` subobject of the `D` object pointed to by `v`. Similarly, if `T` is “reference to `cv1 B`” and `v` has type `cv2 D` such that `B` is a base class of `D`, the result is the unique `B` subobject of the `D` object referred to by `v`.<sup>69</sup> In both the pointer and reference cases, the program is ill-formed if `cv2` has greater cv-qualification than `cv1` or if `B` is an inaccessible or ambiguous base class of `D`. [Example:

```
struct B { };
struct D : B { };
void foo(D* dp) {
    B* bp = dynamic_cast<B*>(dp);    // equivalent to B* bp = dp;
}
```

— end example]

- <sup>6</sup> Otherwise, `v` shall be a pointer to or a glvalue of a polymorphic type (??).
- <sup>7</sup> If `T` is “pointer to `cv void`”, then the result is a pointer to the most derived object pointed to by `v`. Otherwise, a runtime check is applied to see if the object pointed or referred to by `v` can be converted to the type pointed or referred to by `T`.
- <sup>8</sup> If `C` is the class type to which `T` points or refers, the runtime check logically executes as follows:
  - (8.1) — If, in the most derived object pointed (referred) to by `v`, `v` points (refers) to a public base class subobject of a `C` object, and if only one object of type `C` is derived from the subobject pointed (referred) to by `v` the result points (refers) to that `C` object.
  - (8.2) — Otherwise, if `v` points (refers) to a public base class subobject of the most derived object, and the type of the most derived object has a base class, of type `C`, that is unambiguous and public, the result points (refers) to the `C` subobject of the most derived object.
  - (8.3) — Otherwise, the runtime check fails.
- <sup>9</sup> The value of a failed cast to pointer type is the null pointer value of the required result type. A failed cast to reference type throws an exception (??) of a type that would match a handler (??) of type `std::bad_cast` (??).

[Example:

```
class A { virtual void f(); };
class B { virtual void g(); };
```

<sup>69</sup>) The most derived object (??) pointed or referred to by `v` can contain other `B` objects as base classes, but these are ignored.

```

class D : public virtual A, private B { };
void g() {
    D d;
    B* bp = (B*)&d;                                // cast needed to break protection
    A* ap = &d;                                    // public derivation, no cast needed
    D& dr = dynamic_cast<D&>(*bp);              // fails
    ap = dynamic_cast<A*>(bp);                  // fails
    bp = dynamic_cast<B*>(ap);                  // fails
    ap = dynamic_cast<A*>(&d);                  // succeeds
    bp = dynamic_cast<B*>(&d);                  // ill-formed (not a runtime check)
}

class E : public D, public B { };
class F : public E, public D { };
void h() {
    F f;
    A* ap = &f;                                  // succeeds: finds unique A
    D* dp = dynamic_cast<D*>(ap);              // fails: yields null; f has two D subobjects
    E* ep = (E*)ap;                            // ill-formed: cast from virtual base
    E* ep1 = dynamic_cast<E*>(ap);             // succeeds
}

```

— end example ] [ Note: ?? describes the behavior of a `dynamic_cast` applied to an object under construction or destruction. — end note ]

### 8.5.1.8 Type identification

[expr.typeid]

- <sup>1</sup> The result of a `typeid` expression is an lvalue of static type `const std::type_info` (??) and dynamic type `const std::type_info` or `const name` where `name` is an implementation-defined class publicly derived from `std::type_info` which preserves the behavior described in ??.<sup>70</sup> The lifetime of the object referred to by the lvalue extends to the end of the program. Whether or not the destructor is called for the `std::type_info` object at the end of the program is unspecified.
- <sup>2</sup> When `typeid` is applied to a glvalue expression whose type is a polymorphic class type (??), the result refers to a `std::type_info` object representing the type of the most derived object (??) (that is, the dynamic type) to which the glvalue refers. If the glvalue expression is obtained by applying the unary `*` operator to a pointer<sup>71</sup> and the pointer is a null pointer value (??), the `typeid` expression throws an exception (??) of a type that would match a handler of type `std::bad_typeid` exception (??).
- <sup>3</sup> When `typeid` is applied to an expression other than a glvalue of a polymorphic class type, the result refers to a `std::type_info` object representing the static type of the expression. Lvalue-to-rvalue (??), array-to-pointer (??), and function-to-pointer (??) conversions are not applied to the expression. If the expression is a prvalue, the temporary materialization conversion (??) is applied. The expression is an unevaluated operand (??).
- <sup>4</sup> When `typeid` is applied to a *type-id*, the result refers to a `std::type_info` object representing the type of the *type-id*. If the type of the *type-id* is a reference to a possibly cv-qualified type, the result of the `typeid` expression refers to a `std::type_info` object representing the cv-unqualified referenced type. If the type of the *type-id* is a class type or a reference to a class type, the class shall be completely-defined.

<sup>70</sup>) The recommended name for such a class is `extended_type_info`.

<sup>71</sup>) If `p` is an expression of pointer type, then `*p`, `(*p)`, `*(p)`, `((*p))`, `*((p))`, and so on all meet this requirement.

- <sup>5</sup> If the type of the expression or *type-id* is a cv-qualified type, the result of the `typeid` expression refers to a `std::type_info` object representing the cv-unqualified type. [ *Example*:

```
class D { /* ... */ };
D d1;
const D d2;

typeid(d1) == typeid(d2);           // yields true
typeid(D) == typeid(const D);     // yields true
typeid(D) == typeid(d2);           // yields true
typeid(D) == typeid(const D&);    // yields true

— end example]
```

- <sup>6</sup> If the header `<typeinfo>` (??) is not included prior to a use of `typeid`, the program is ill-formed.

- <sup>7</sup> [ *Note*: ?? describes the behavior of `typeid` applied to an object under construction or destruction. — *end note* ]

### 8.5.1.9 Static cast

[`expr.static.cast`]

- <sup>1</sup> The result of the expression `static_cast<T>(v)` is the result of converting the expression *v* to type *T*. If *T* is an lvalue reference type or an rvalue reference to function type, the result is an lvalue; if *T* is an rvalue reference to object type, the result is an xvalue; otherwise, the result is a prvalue. The `static_cast` operator shall not cast away constness (??).
- <sup>2</sup> An lvalue of type “*cv1 B*”, where *B* is a class type, can be cast to type “reference to *cv2 D*”, where *D* is a class derived (??) from *B*, if *cv2* is the same cv-qualification as, or greater cv-qualification than, *cv1*. If *B* is a virtual base class of *D* or a base class of a virtual base class of *D*, or if no valid standard conversion from “pointer to *D*” to “pointer to *B*” exists (??), the program is ill-formed. An xvalue of type “*cv1 B*” can be cast to type “rvalue reference to *cv2 D*” with the same constraints as for an lvalue of type “*cv1 B*”. If the object of type “*cv1 B*” is actually a base class subobject of an object of type *D*, the result refers to the enclosing object of type *D*. Otherwise, the behavior is undefined. [ *Example*:

```
struct B {};
struct D : public B {};
D d;
B &br = d;

static_cast<D&>(br);           // produces lvalue to the original d object

— end example]
```

- <sup>3</sup> An lvalue of type “*cv1 T1*” can be cast to type “rvalue reference to *cv2 T2*” if “*cv2 T2*” is reference-compatible with “*cv1 T1*” (??). If the value is not a bit-field, the result refers to the object or the specified base class subobject thereof; otherwise, the lvalue-to-rvalue conversion (??) is applied to the bit-field and the resulting prvalue is used as the *expression* of the `static_cast` for the remainder of this subclause. If *T2* is an inaccessible (??) or ambiguous (??) base class of *T1*, a program that necessitates such a cast is ill-formed.
- <sup>4</sup> An expression *e* can be explicitly converted to a type *T* if there is an implicit conversion sequence (??) from *e* to *T*, or if overload resolution for a direct-initialization (??) of an object or reference of type *T* from *e* would find at least one viable function (??). If *T* is a reference type, the effect is the same as performing the declaration and initialization

```
T t(e);
```

for some invented temporary variable *t* (??) and then using the temporary variable as the result of the conversion. Otherwise, the result object is direct-initialized from *e*. [ *Note*: The conversion is ill-formed when attempting to convert an expression of class type to an inaccessible or ambiguous base class. — *end note* ]

- 5 Otherwise, the `static_cast` shall perform one of the conversions listed below. No other conversion shall be performed explicitly using a `static_cast`.
- 6 Any expression can be explicitly converted to type *cv void*, in which case it becomes a discarded-value expression (??). [ *Note*: However, if the value is in a temporary object (??), the destructor for that object is not executed until the usual time, and the value of the object is preserved for the purpose of executing the destructor. — *end note* ]
- 7 The inverse of any standard conversion sequence (??) not containing an lvalue-to-rvalue (??), array-to-pointer (??), function-to-pointer (??), null pointer (??), null member pointer (??), boolean (??), or function pointer (??) conversion, can be performed explicitly using `static_cast`. A program is ill-formed if it uses `static_cast` to perform the inverse of an ill-formed standard conversion sequence. [ *Example*:

```
struct B {};
struct D : private B {};
void f() {
    static_cast<D*>((B*)0);           // error: B is a private base of D
    static_cast<int B::*>((int D::*)0); // error: B is a private base of D
}
```

— *end example* ]

- 8 The lvalue-to-rvalue (??), array-to-pointer (??), and function-to-pointer (??) conversions are applied to the operand. Such a `static_cast` is subject to the restriction that the explicit conversion does not cast away constness (??), and the following additional rules for specific cases:
- 9 A value of a scoped enumeration type (??) can be explicitly converted to an integral type. When that type is *cv bool*, the resulting value is `false` if the original value is zero and `true` for all other values. For the remaining integral types, the value is unchanged if the original value can be represented by the specified type. Otherwise, the resulting value is unspecified. A value of a scoped enumeration type can also be explicitly converted to a floating-point type; the result is the same as that of converting from the original value to the floating-point type.
- 10 A value of integral or enumeration type can be explicitly converted to a complete enumeration type. If the enumeration type has a fixed underlying type, the value is first converted to that type by integral conversion, if necessary, and then to the enumeration type. If the enumeration type does not have a fixed underlying type, the value is unchanged if the original value is within the range of the enumeration values (??), and otherwise, the behavior is undefined. A value of floating-point type can also be explicitly converted to an enumeration type. The resulting value is the same as converting the original value to the underlying type of the enumeration (??), and subsequently to the enumeration type.
- 11 A prvalue of type “pointer to *cv1 B*”, where *B* is a class type, can be converted to a prvalue of type “pointer to *cv2 D*”, where *D* is a class derived (??) from *B*, if *cv2* is the same cv-qualification as, or greater cv-qualification than, *cv1*. If *B* is a virtual base class of *D* or a base class of a virtual base class of *D*, or if no valid standard conversion from “pointer to *D*” to “pointer to *B*” exists (??), the program is ill-formed. The null pointer value (??) is converted to the null pointer value of the destination type. If the prvalue of type “pointer to *cv1 B*” points to a *B* that is actually a subobject of an object of type *D*, the resulting pointer points to the enclosing object of type *D*. Otherwise, the behavior is undefined.

- <sup>12</sup> A prvalue of type “pointer to member of D of type *cv1 T*” can be converted to a prvalue of type “pointer to member of B of type *cv2 T*”, where B is a base class (?) of D, if *cv2* is the same cv-qualification as, or greater cv-qualification than, *cv1*.<sup>72</sup> If no valid standard conversion from “pointer to member of B of type T” to “pointer to member of D of type T” exists (??), the program is ill-formed. The null member pointer value (?) is converted to the null member pointer value of the destination type. If class B contains the original member, or is a base or derived class of the class containing the original member, the resulting pointer to member points to the original member. Otherwise, the behavior is undefined. [Note: Although class B need not contain the original member, the dynamic type of the object with which indirection through the pointer to member is performed must contain the original member; see ??. —end note]
- <sup>13</sup> A prvalue of type “pointer to *cv1 void*” can be converted to a prvalue of type “pointer to *cv2 T*”, where T is an object type and *cv2* is the same cv-qualification as, or greater cv-qualification than, *cv1*. If the original pointer value represents the address A of a byte in memory and A does not satisfy the alignment requirement of T, then the resulting pointer value is unspecified. Otherwise, if the original pointer value points to an object *a*, and there is an object *b* of type T (ignoring cv-qualification) that is pointer-interconvertible (?) with *a*, the result is a pointer to *b*. Otherwise, the pointer value is unchanged by the conversion. [Example:

```
T* p1 = new T;
const T* p2 = static_cast<const T*>(static_cast<void*>(p1));
bool b = p1 == p2; // b will have the value true.
```

—end example]

### 8.5.1.10 Reinterpret cast

[expr.reinterpret.cast]

- <sup>1</sup> The result of the expression `reinterpret_cast<T>(v)` is the result of converting the expression v to type T. If T is an lvalue reference type or an rvalue reference to function type, the result is an lvalue; if T is an rvalue reference to object type, the result is an xvalue; otherwise, the result is a prvalue and the lvalue-to-rvalue (?), array-to-pointer (?), and function-to-pointer (?) standard conversions are performed on the expression v. Conversions that can be performed explicitly using `reinterpret_cast` are listed below. No other conversion can be performed explicitly using `reinterpret_cast`.
- <sup>2</sup> The `reinterpret_cast` operator shall not cast away constness (??). An expression of integral, enumeration, pointer, or pointer-to-member type can be explicitly converted to its own type; such a cast yields the value of its operand.
- <sup>3</sup> [Note: The mapping performed by `reinterpret_cast` might, or might not, produce a representation different from the original value. —end note]
- <sup>4</sup> A pointer can be explicitly converted to any integral type large enough to hold it. The mapping function is implementation-defined. [Note: It is intended to be unsurprising to those who know the addressing structure of the underlying machine. —end note] A value of type `std::nullptr_t` can be converted to an integral type; the conversion has the same meaning and validity as a conversion of `(void*)0` to the integral type. [Note: A `reinterpret_cast` cannot be used to convert a value of any type to the type `std::nullptr_t`. —end note]
- <sup>5</sup> A value of integral type or enumeration type can be explicitly converted to a pointer. A pointer converted to an integer of sufficient size (if any such exists on the implementation) and back to the same pointer type will have its original value; mappings between pointers and integers are otherwise implementation-defined. [Note: Except as described in ??, the result of such a conversion will not be a safely-derived pointer value. —end note]

<sup>72</sup>) Function types (including those used in pointer-to-member-function types) are never cv-qualified; see ??.

- <sup>6</sup> A function pointer can be explicitly converted to a function pointer of a different type. [ *Note:* The effect of calling a function through a pointer to a function type (??) that is not the same as the type used in the definition of the function is undefined. — *end note* ] Except that converting a prvalue of type “pointer to T1” to the type “pointer to T2” (where T1 and T2 are function types) and back to its original type yields the original pointer value, the result of such a pointer conversion is unspecified. [ *Note:* See also ?? for more details of pointer conversions. — *end note* ]
- <sup>7</sup> An object pointer can be explicitly converted to an object pointer of a different type.<sup>73</sup> When a prvalue v of object pointer type is converted to the object pointer type “pointer to cv T”, the result is `static_cast<cv T*>(static_cast<cv void*>(v))`. [ *Note:* Converting a prvalue of type “pointer to T1” to the type “pointer to T2” (where T1 and T2 are object types and where the alignment requirements of T2 are no stricter than those of T1) and back to its original type yields the original pointer value. — *end note* ]
- <sup>8</sup> Converting a function pointer to an object pointer type or vice versa is conditionally-supported. The meaning of such a conversion is implementation-defined, except that if an implementation supports conversions in both directions, converting a prvalue of one type to the other type and back, possibly with different cv-qualification, shall yield the original pointer value.
- <sup>9</sup> The null pointer value (??) is converted to the null pointer value of the destination type. [ *Note:* A null pointer constant of type `std::nullptr_t` cannot be converted to a pointer type, and a null pointer constant of integral type is not necessarily converted to a null pointer value. — *end note* ]
- <sup>10</sup> A prvalue of type “pointer to member of X of type T1” can be explicitly converted to a prvalue of a different type “pointer to member of Y of type T2” if T1 and T2 are both function types or both object types.<sup>74</sup> The null member pointer value (??) is converted to the null member pointer value of the destination type. The result of this conversion is unspecified, except in the following cases:
  - (10.1) — converting a prvalue of type “pointer to member function” to a different pointer-to-member-function type and back to its original type yields the original pointer-to-member value.
  - (10.2) — converting a prvalue of type “pointer to data member of X of type T1” to the type “pointer to data member of Y of type T2” (where the alignment requirements of T2 are no stricter than those of T1) and back to its original type yields the original pointer-to-member value.
- <sup>11</sup> A glvalue expression of type T1, designating an object x, can be cast to the type “reference to T2” if an expression of type “pointer to T1” can be explicitly converted to the type “pointer to T2” using a `reinterpret_cast`. The result is that of `*reinterpret_cast<T2 *>(p)` where p is a pointer to x of type “pointer to T1”. No temporary is created, no copy is made, and no constructors (??) or conversion functions (??) are called.<sup>75</sup>

### 8.5.1.11 Const cast

[`expr.const.cast`]

- <sup>1</sup> The result of the expression `const_cast<T>(v)` is of type T. If T is an lvalue reference to object type, the result is an lvalue; if T is an rvalue reference to object type, the result is an xvalue; otherwise, the result is a prvalue and the lvalue-to-rvalue (??), array-to-pointer (??), and function-to-pointer (??) standard conversions are performed on the expression v. Conversions that can be performed explicitly using `const_cast` are listed below. No other conversion shall be performed explicitly using `const_cast`.

<sup>73</sup>) The types may have different cv-qualifiers, subject to the overall restriction that a `reinterpret_cast` cannot cast away constness.

<sup>74</sup>) T1 and T2 may have different cv-qualifiers, subject to the overall restriction that a `reinterpret_cast` cannot cast away constness.

<sup>75</sup>) This is sometimes referred to as a *type pun* when the result refers to the same object as the source glvalue.

- <sup>2</sup> [Note: Subject to the restrictions in this subclause, an expression may be cast to its own type using a `const_cast` operator. —end note]
- <sup>3</sup> For two similar types T1 and T2 (??), a prvalue of type T1 may be explicitly converted to the type T2 using a `const_cast`. The result of a `const_cast` refers to the original entity. [Example:

```
typedef int *A[3];           // array of 3 pointer to int
typedef const int *const CA[3]; // array of 3 const pointer to const int

CA &&r = A{}; // OK, reference binds to temporary array object after qualification conversion to type CA
A &&r1 = const_cast<A>(CA{}); // error: temporary array decayed to pointer
A &&r2 = const_cast<A&&>(CA{}); // OK
```

—end example]

- <sup>4</sup> For two object types T1 and T2, if a pointer to T1 can be explicitly converted to the type “pointer to T2” using a `const_cast`, then the following conversions can also be made:
- (4.1) — an lvalue of type T1 can be explicitly converted to an lvalue of type T2 using the cast `const_cast<T2&>`;
  - (4.2) — a glvalue of type T1 can be explicitly converted to an xvalue of type T2 using the cast `const_cast<T2&&>`; and
  - (4.3) — if T1 is a class type, a prvalue of type T1 can be explicitly converted to an xvalue of type T2 using the cast `const_cast<T2&&>`.

The result of a reference `const_cast` refers to the original object if the operand is a glvalue and to the result of applying the temporary materialization conversion (??) otherwise.

- <sup>5</sup> A null pointer value (??) is converted to the null pointer value of the destination type. The null member pointer value (??) is converted to the null member pointer value of the destination type.
- <sup>6</sup> [Note: Depending on the type of the object, a write operation through the pointer, lvalue or pointer to data member resulting from a `const_cast` that casts away a const-qualifier<sup>76</sup> may produce undefined behavior (??). —end note]
- <sup>7</sup> A conversion from a type T1 to a type T2 *casts away constness* if T1 and T2 are different, there is a cv-decomposition (??) of T1 yielding n such that T2 has a cv-decomposition of the form

$$cv_0^2 P_0^2 cv_1^2 P_1^2 \cdots cv_{n-1}^2 P_{n-1}^2 cv_n^2 U_2,$$

and there is no qualification conversion that converts T1 to

$$cv_0^2 P_0^1 cv_1^2 P_1^1 \cdots cv_{n-1}^2 P_{n-1}^1 cv_n^2 U_1.$$

- <sup>8</sup> Casting from an lvalue of type T1 to an lvalue of type T2 using an lvalue reference cast or casting from an expression of type T1 to an xvalue of type T2 using an rvalue reference cast casts away constness if a cast from a prvalue of type “pointer to T1” to the type “pointer to T2” casts away constness.
- <sup>9</sup> [Note: Some conversions which involve only changes in cv-qualification cannot be done using `const_cast`. For instance, conversions between pointers to functions are not covered because such conversions lead to values whose use causes undefined behavior. For the same reasons, conversions between pointers to member functions, and in particular, the conversion from a pointer to a const member function to a pointer to a non-const member function, are not covered. —end note]

<sup>76</sup>) `const_cast` is not limited to conversions that cast away a const-qualifier.

## 8.5.2 Unary expressions

[expr.unary]

- 1 Expressions with unary operators group right-to-left.

```
unary-expression:
  postfix-expression
  ++ cast-expression
  -- cast-expression
  unary-operator cast-expression
  sizeof unary-expression
  sizeof ( type-id )
  sizeof ... ( identifier )
  alignof ( type-id )
  noexcept-expression
  new-expression
  delete-expression

unary-operator: one of
  * & + - ! ~
```

### 8.5.2.1 Unary operators

[expr.unary.op]

- 1 The unary **\*** operator performs *indirection*: the expression to which it is applied shall be a pointer to an object type, or a pointer to a function type and the result is an lvalue referring to the object or function to which the expression points. If the type of the expression is “pointer to T”, the type of the result is “T”. [ *Note*: Indirection through a pointer to an incomplete type (other than *cv void*) is valid. The lvalue thus obtained can be used in limited ways (to initialize a reference, for example); this lvalue must not be converted to a prvalue, see **??**. — *end note* ]
- 2 The result of each of the following unary operators is a prvalue.
- 3 The result of the unary **&** operator is a pointer to its operand. The operand shall be an lvalue or a *qualified-id*. If the operand is a *qualified-id* naming a non-static or variant member **m** of some class **C** with type **T**, the result has type “pointer to member of class **C** of type **T**” and is a prvalue designating **C::m**. Otherwise, if the type of the expression is **T**, the result has type “pointer to **T**” and is a prvalue that is the address of the designated object **(??)** or a pointer to the designated function. [ *Note*: In particular, the address of an object of type “*cv T*” is “pointer to *cv T*”, with the same *cv*-qualification. — *end note* ] For purposes of pointer arithmetic **(??)** and comparison **(??, ??)**, an object that is not an array element whose address is taken in this way is considered to belong to an array with one element of type **T**. [ *Example*:

```
struct A { int i; };
struct B : A { };
... &B::i ...           // has type int A::*
int a;
int* p1 = &a;
int* p2 = p1 + 1;    // defined behavior
bool b = p2 > p1;   // defined behavior, with value true
```

— *end example*] [ *Note*: A pointer to member formed from a **mutable** non-static data member **(??)** does not reflect the **mutable** specifier associated with the non-static data member. — *end note* ]

- 4 A pointer to member is only formed when an explicit **&** is used and its operand is a *qualified-id* not enclosed in parentheses. [ *Note*: That is, the expression **&(qualified-id)**, where the *qualified-id* is enclosed in parentheses, does not form an expression of type “pointer to member”. Neither does **qualified-id**, because

there is no implicit conversion from a *qualified-id* for a non-static member function to the type “pointer to member function” as there is from an lvalue of function type to the type “pointer to function” (??). Nor is **&unqualified-id** a pointer to member, even within the scope of the *unqualified-id*’s class. — *end note*]

- 5 If **&** is applied to an lvalue of incomplete class type and the complete type declares **operator&()**, it is unspecified whether the operator has the built-in meaning or the operator function is called. The operand of **&** shall not be a bit-field.
- 6 The address of an overloaded function (??) can be taken only in a context that uniquely determines which version of the overloaded function is referred to (see ??). [Note: Since the context might determine whether the operand is a static or non-static member function, the context can also affect whether the expression has type “pointer to function” or “pointer to member function”. — *end note*]
- 7 The operand of the unary **+** operator shall have arithmetic, unscoped enumeration, or pointer type and the result is the value of the argument. Integral promotion is performed on integral or enumeration operands. The type of the result is the type of the promoted operand.
- 8 The operand of the unary **-** operator shall have arithmetic or unscoped enumeration type and the result is the negation of its operand. Integral promotion is performed on integral or enumeration operands. The negative of an unsigned quantity is computed by subtracting its value from  $2^n$ , where  $n$  is the number of bits in the promoted operand. The type of the result is the type of the promoted operand.
- 9 The operand of the logical negation operator **!** is contextually converted to **bool** (??); its value is **true** if the converted operand is **false** and **false** otherwise. The type of the result is **bool**.
- 10 The operand of **~** shall have integral or unscoped enumeration type; the result is the ones’ complement of its operand. Integral promotions are performed. The type of the result is the type of the promoted operand. There is an ambiguity in the grammar when **~** is followed by a *class-name* or *decltype-specifier*. The ambiguity is resolved by treating **~** as the unary complement operator rather than as the start of an *unqualified-id* naming a destructor. [Note: Because the grammar does not permit an operator to follow the **.**, **->**, or **:** tokens, a **~** followed by a *class-name* or *decltype-specifier* in a member access expression or *qualified-id* is unambiguously parsed as a destructor name. — *end note*]

### 8.5.2.2 Increment and decrement

[expr.pre.incr]

- 1 The operand of prefix **++** is modified by adding 1. The operand shall be a modifiable lvalue. The type of the operand shall be an arithmetic type other than **cv bool**, or a pointer to a completely-defined object type. The result is the updated operand; it is an lvalue, and it is a bit-field if the operand is a bit-field. The expression **++x** is equivalent to **x+=1**. [Note: See the discussions of addition (??) and assignment operators (??) for information on conversions. — *end note*]
- 2 The operand of prefix **--** is modified by subtracting 1. The requirements on the operand of prefix **--** and the properties of its result are otherwise the same as those of prefix **++**. [Note: For postfix increment and decrement, see ??.. — *end note*]

### 8.5.2.3 Sizeof

[expr.sizeof]

- 1 The **sizeof** operator yields the number of bytes in the object representation of its operand. The operand is either an expression, which is an unevaluated operand (??), or a parenthesized *type-id*. The **sizeof** operator shall not be applied to an expression that has function or incomplete type, to the parenthesized name of such types, or to a glvalue that designates a bit-field. **sizeof(char)**, **sizeof(signed char)** and **sizeof(unsigned char)** are 1. The result of **sizeof** applied to any other fundamental type (??) is implementation-defined. [Note: In particular, **sizeof(bool)**, **sizeof(char16\_t)**, **sizeof(char32\_t)**, and

`sizeof(wchar_t)` are implementation-defined.<sup>77</sup> — end note] [Note: See ?? for the definition of *byte* and ?? for the definition of *object representation*. — end note]

- 2 When applied to a reference or a reference type, the result is the size of the referenced type. When applied to a class, the result is the number of bytes in an object of that class including any padding required for placing objects of that type in an array. The size of a most derived class shall be greater than zero (??). The result of applying `sizeof` to a base class subobject is the size of the base class type.<sup>78</sup> When applied to an array, the result is the total number of bytes in the array. This implies that the size of an array of *n* elements is *n* times the size of an element.
- 3 The `sizeof` operator can be applied to a pointer to a function, but shall not be applied directly to a function.
- 4 The lvalue-to-rvalue (??), array-to-pointer (??), and function-to-pointer (??) standard conversions are not applied to the operand of `sizeof`. If the operand is a prvalue, the temporary materialization conversion (??) is applied.
- 5 The identifier in a `sizeof...` expression shall name a parameter pack. The `sizeof...` operator yields the number of arguments provided for the parameter pack *identifier*. A `sizeof...` expression is a pack expansion (??). [Example:

```
template<class... Types>
struct count {
    static const std::size_t value = sizeof...(Types);
};

— end example]
```

- 6 The result of `sizeof` and `sizeof...` is a constant of type `std::size_t`. [Note: `std::size_t` is defined in the standard header <cstddef> (??, ??). — end note]

#### 8.5.2.4 New

[expr.new]

- 1 The *new-expression* attempts to create an object of the *type-id* (??) or *new-type-id* to which it is applied. The type of that object is the *allocated type*. This type shall be a complete object type, but not an abstract class type or array thereof (??, ??, ??). [Note: Because references are not objects, references cannot be created by *new-expressions*. — end note] [Note: The *type-id* may be a cv-qualified type, in which case the object created by the *new-expression* has a cv-qualified type. — end note]

```
new-expression:
  ::opt new new-placementopt new-type-id new-initializeropt
  ::opt new new-placementopt ( type-id ) new-initializeropt

new-placement:
  ( expression-list )

new-type-id:
  type-specifier-seq new-declaratoropt

new-declarator:
  ptr-operator new-declaratoropt
  noptr-new-declarator
```

77) `sizeof(bool)` is not required to be 1.

78) The actual size of a base class subobject may be less than the result of applying `sizeof` to the subobject, due to virtual base classes and less strict padding requirements on base class subobjects.

```

noptr-new-declarator:
  [ expression ] attribute-specifier-seqopt
  noptr-new-declarator [ constant-expression ] attribute-specifier-seqopt

new-initializer:
  ( expression-listopt )
  braced-init-list

```

Entities created by a *new-expression* have dynamic storage duration (??). [Note: The lifetime of such an entity is not necessarily restricted to the scope in which it is created. —end note] If the entity is a non-array object, the result of the *new-expression* is a pointer to the object created. If it is an array, the result of the *new-expression* is a pointer to the initial element of the array.

- 2 If a placeholder type (??) appears in the *type-specifier-seq* of a *new-type-id* or *type-id* of a *new-expression*, the allocated type is deduced as follows: Let *init* be the *new-initializer*, if any, and *T* be the *new-type-id* or *type-id* of the *new-expression*, then the allocated type is the type deduced for the variable *x* in the invented declaration (??):

```
T x init ;
```

[Example:

```

new auto(1);           // allocated type is int
auto x = new auto('a'); // allocated type is char, x is of type char*

template<class T> struct A { A(T, T); };
auto y = new A{1, 2};   // allocated type is A<int>

```

—end example]

- 3 The *new-type-id* in a *new-expression* is the longest possible sequence of *new-declarators*. [Note: This prevents ambiguities between the declarator operators &, &&, \*, and [] and their expression counterparts. —end note] [Example:

```
new int * i;           // syntax error: parsed as (new int*) i, not as (new int)*i
```

The \* is the pointer declarator and not the multiplication operator. —end example]

- 4 [Note: Parentheses in a *new-type-id* of a *new-expression* can have surprising effects. [Example:

```
new int(*[10])();      // error
```

is ill-formed because the binding is

```
(new int) (*[10])();    // error
```

Instead, the explicitly parenthesized version of the **new** operator can be used to create objects of compound types (??):

```
new (int (*[10]))();
```

allocates an array of 10 pointers to functions (taking no argument and returning **int**). —end example]  
—end note]

- 5 When the allocated object is an array (that is, the *noptr-new-declarator* syntax is used or the *new-type-id* or *type-id* denotes an array type), the *new-expression* yields a pointer to the initial element (if any) of the array. [Note: Both **new int** and **new int[10]** have type **int\*** and the type of **new int[i][10]** is **int (\*)[10]**. —end note] The *attribute-specifier-seq* in a *noptr-new-declarator* appertains to the associated array type.

- 6 Every *constant-expression* in a *noptr-new-declarator* shall be a converted constant expression (??) of type **std::size\_t** and shall evaluate to a strictly positive value. The *expression* in a *noptr-new-declarator* is

implicitly converted to `std::size_t`. [Example: Given the definition `int n = 42, new float[n]` [5] is well-formed (because `n` is the *expression* of a *noptr-new-declarator*), but `new float[5][n]` is ill-formed (because `n` is not a constant expression). — end example]

7 The *expression* in a *noptr-new-declarator* is erroneous if:

- (7.1) — the expression is of non-class type and its value before converting to `std::size_t` is less than zero;
- (7.2) — the expression is of class type and its value before application of the second standard conversion (??)<sup>79</sup> is less than zero;
- (7.3) — its value is such that the size of the allocated object would exceed the implementation-defined limit (??); or
- (7.4) — the *new-initializer* is a *braced-init-list* and the number of array elements for which initializers are provided (including the terminating '\0' in a string literal (??)) exceeds the number of elements to initialize.

If the *expression* is erroneous after converting to `std::size_t`:

- (7.5) — if the *expression* is a core constant expression, the program is ill-formed;
- (7.6) — otherwise, an allocation function is not called; instead
  - (7.6.1) — if the allocation function that would have been called has a non-throwing exception specification (??), the value of the *new-expression* is the null pointer value of the required result type;
  - (7.6.2) — otherwise, the *new-expression* terminates by throwing an exception of a type that would match a handler (??) of type `std::bad_array_new_length` (??).

When the value of the *expression* is zero, the allocation function is called to allocate an array with no elements.

- 8 A *new-expression* may obtain storage for the object by calling an allocation function (??). If the *new-expression* terminates by throwing an exception, it may release storage by calling a deallocation function (??). If the allocated type is a non-array type, the allocation function's name is `operator new` and the deallocation function's name is `operator delete`. If the allocated type is an array type, the allocation function's name is `operator new[]` and the deallocation function's name is `operator delete[]`. [Note: An implementation shall provide default definitions for the global allocation functions (??, ??, ??). A C++ program can provide alternative definitions of these functions (??) and/or class-specific versions (??). The set of allocation and deallocation functions that may be called by a *new-expression* may include functions that do not perform allocation or deallocation; for example, see ??]. — end note]
- 9 If the *new-expression* begins with a unary `::` operator, the allocation function's name is looked up in the global scope. Otherwise, if the allocated type is a class type `T` or array thereof, the allocation function's name is looked up in the scope of `T`. If this lookup fails to find the name, or if the allocated type is not a class type, the allocation function's name is looked up in the global scope.
- 10 An implementation is allowed to omit a call to a replaceable global allocation function (??, ??). When it does so, the storage is instead provided by the implementation or provided by extending the allocation of another *new-expression*. The implementation may extend the allocation of a *new-expression* `e1` to provide storage for a *new-expression* `e2` if the following would be true were the allocation not extended:
  - (10.1) — the evaluation of `e1` is sequenced before the evaluation of `e2`, and

---

<sup>79</sup>) If the conversion function returns a signed integer type, the second standard conversion converts to the unsigned type `std::size_t` and thus thwarts any attempt to detect a negative value afterwards.

- (10.2) — **e2** is evaluated whenever **e1** obtains storage, and
- (10.3) — both **e1** and **e2** invoke the same replaceable global allocation function, and
- (10.4) — if the allocation function invoked by **e1** and **e2** is throwing, any exceptions thrown in the evaluation of either **e1** or **e2** would be first caught in the same handler, and
- (10.5) — the pointer values produced by **e1** and **e2** are operands to evaluated *delete-expressions*, and
- (10.6) — the evaluation of **e2** is sequenced before the evaluation of the *delete-expression* whose operand is the pointer value produced by **e1**.

[*Example:*

```
void mergeable(int x) {
    // These allocations are safe for merging:
    std::unique_ptr<char[]> a{new (std::nothrow) char[8]};
    std::unique_ptr<char[]> b{new (std::nothrow) char[8]};
    std::unique_ptr<char[]> c{new (std::nothrow) char[x]};

    g(a.get(), b.get(), c.get());
}

void unmergeable(int x) {
    std::unique_ptr<char[]> a{new char[8]};
    try {
        // Merging this allocation would change its catch handler.
        std::unique_ptr<char[]> b{new char[x]};
    } catch (const std::bad_alloc& e) {
        std::cerr << "Allocation failed: " << e.what() << std::endl;
        throw;
    }
}
```

— *end example*]

- <sup>11</sup> When a *new-expression* calls an allocation function and that allocation has not been extended, the *new-expression* passes the amount of space requested to the allocation function as the first argument of type `std::size_t`. That argument shall be no less than the size of the object being created; it may be greater than the size of the object being created only if the object is an array. For arrays of `char`, `unsigned char`, and `std::byte`, the difference between the result of the *new-expression* and the address returned by the allocation function shall be an integral multiple of the strictest fundamental alignment requirement (??) of any object type whose size is no greater than the size of the array being created. [ *Note:* Because allocation functions are assumed to return pointers to storage that is appropriately aligned for objects of any type with fundamental alignment, this constraint on array allocation overhead permits the common idiom of allocating character arrays into which objects of other types will later be placed. — *end note* ]
- <sup>12</sup> When a *new-expression* calls an allocation function and that allocation has been extended, the size argument to the allocation call shall be no greater than the sum of the sizes for the omitted calls as specified above, plus the size for the extended call had it not been extended, plus any padding necessary to align the allocated objects within the allocated memory.
- <sup>13</sup> The *new-placement* syntax is used to supply additional arguments to an allocation function; such an expression is called a *placement new-expression*.

<sup>14</sup> Overload resolution is performed on a function call created by assembling an argument list. The first argument is the amount of space requested, and has type `std::size_t`. If the type of the allocated object has new-extended alignment, the next argument is the type's alignment, and has type `std::align_val_t`. If the *new-placement* syntax is used, the *initializer-clauses* in its *expression-list* are the succeeding arguments. If no matching function is found and the allocated object type has new-extended alignment, the alignment argument is removed from the argument list, and overload resolution is performed again.

<sup>15</sup> [ *Example:*

(15.1) — `new T` results in one of the following calls:

```
operator new(sizeof(T))
operator new(sizeof(T), std::align_val_t(alignof(T)))
```

(15.2) — `new(2,f)` `T` results in one of the following calls:

```
operator new(sizeof(T), 2, f)
operator new(sizeof(T), std::align_val_t(alignof(T)), 2, f)
```

(15.3) — `new T[5]` results in one of the following calls:

```
operator new[](sizeof(T) * 5 + x)
operator new[](sizeof(T) * 5 + x, std::align_val_t(alignof(T)))
```

(15.4) — `new(2,f) T[5]` results in one of the following calls:

```
operator new[](sizeof(T) * 5 + x, 2, f)
operator new[](sizeof(T) * 5 + x, std::align_val_t(alignof(T)), 2, f)
```

Here, each instance of `x` is a non-negative unspecified value representing array allocation overhead; the result of the *new-expression* will be offset by this amount from the value returned by `operator new[]`. This overhead may be applied in all array *new-expressions*, including those referencing the library function `operator new[](std::size_t, void*)` and other placement allocation functions. The amount of overhead may vary from one invocation of `new` to another. — *end example* ]

<sup>16</sup> [ *Note:* Unless an allocation function has a non-throwing exception specification (??), it indicates failure to allocate storage by throwing a `std::bad_alloc` exception (??, ??, ??); it returns a non-null pointer otherwise. If the allocation function has a non-throwing exception specification, it returns null to indicate failure to allocate storage and a non-null pointer otherwise. — *end note*] If the allocation function is a non-allocating form (??) that returns null, the behavior is undefined. Otherwise, if the allocation function returns null, initialization shall not be done, the deallocation function shall not be called, and the value of the *new-expression* shall be null.

<sup>17</sup> [ *Note:* When the allocation function returns a value other than null, it must be a pointer to a block of storage in which space for the object has been reserved. The block of storage is assumed to be appropriately aligned and of the requested size. The address of the created object will not necessarily be the same as that of the block if the object is an array. — *end note* ]

<sup>18</sup> A *new-expression* that creates an object of type `T` initializes that object as follows:

(18.1) — If the *new-initializer* is omitted, the object is default-initialized (??). [ *Note:* If no initialization is performed, the object has an indeterminate value. — *end note* ]

(18.2) — Otherwise, the *new-initializer* is interpreted according to the initialization rules of ?? for direct-initialization.

<sup>19</sup> The invocation of the allocation function is sequenced before the evaluations of expressions in the *new-initializer*. Initialization of the allocated object is sequenced before the value computation of the *new-expression*.

- <sup>20</sup> If the *new-expression* creates an object or an array of objects of class type, access and ambiguity control are done for the allocation function, the deallocation function (??), and the constructor (??). If the *new-expression* creates an array of objects of class type, the destructor is potentially invoked (??).
- <sup>21</sup> If any part of the object initialization described above<sup>80</sup> terminates by throwing an exception and a suitable deallocation function can be found, the deallocation function is called to free the memory in which the object was being constructed, after which the exception continues to propagate in the context of the *new-expression*. If no unambiguous matching deallocation function can be found, propagating the exception does not cause the object's memory to be freed. [ *Note:* This is appropriate when the called allocation function does not allocate memory; otherwise, it is likely to result in a memory leak. — *end note* ]
- <sup>22</sup> If the *new-expression* begins with a unary :: operator, the deallocation function's name is looked up in the global scope. Otherwise, if the allocated type is a class type T or an array thereof, the deallocation function's name is looked up in the scope of T. If this lookup fails to find the name, or if the allocated type is not a class type or array thereof, the deallocation function's name is looked up in the global scope.
- <sup>23</sup> A declaration of a placement deallocation function matches the declaration of a placement allocation function if it has the same number of parameters and, after parameter transformations (??), all parameter types except the first are identical. If the lookup finds a single matching deallocation function, that function will be called; otherwise, no deallocation function will be called. If the lookup finds a usual deallocation function with a parameter of type std::size\_t (??) and that function, considered as a placement deallocation function, would have been selected as a match for the allocation function, the program is ill-formed. For a non-placement allocation function, the normal deallocation function lookup is used to find the matching deallocation function (??) [ *Example:*

```
struct S {
    // Placement allocation function:
    static void* operator new(std::size_t, std::size_t);

    // Usual (non-placement) deallocation function:
    static void operator delete(void*, std::size_t);
};

S* p = new (0) S;    // ill-formed: non-placement deallocation function matches
                     // placement allocation function
— end example ]
```

- <sup>24</sup> If a *new-expression* calls a deallocation function, it passes the value returned from the allocation function call as the first argument of type void\*. If a placement deallocation function is called, it is passed the same additional arguments as were passed to the placement allocation function, that is, the same arguments as those specified with the *new-placement* syntax. If the implementation is allowed to introduce a temporary object or make a copy of any argument as part of the call to the allocation function, it is unspecified whether the same object is used in the call to both the allocation and deallocation functions.

### 8.5.2.5 Delete

[expr.delete]

- <sup>1</sup> The *delete-expression* operator destroys a most derived object (??) or array created by a *new-expression*.

```
delete-expression:
  ::opt delete cast-expression
  ::opt delete [ ] cast-expression
```

<sup>80</sup>) This may include evaluating a *new-initializer* and/or calling a constructor.

The first alternative is a *single-object delete expression*, and the second is an *array delete expression*. Whenever the `delete` keyword is immediately followed by empty square brackets, it shall be interpreted as the second alternative.<sup>81</sup> The operand shall be of pointer to object type or of class type. If of class type, the operand is contextually implicitly converted (??) to a pointer to object type.<sup>82</sup> The *delete-expression*'s result has type `void`.

- 2 If the operand has a class type, the operand is converted to a pointer type by calling the above-mentioned conversion function, and the converted operand is used in place of the original operand for the remainder of this subclause. In a single-object delete expression, the value of the operand of `delete` may be a null pointer value, a pointer to a non-array object created by a previous *new-expression*, or a pointer to a subobject (??) representing a base class of such an object (??). If not, the behavior is undefined. In an array delete expression, the value of the operand of `delete` may be a null pointer value or a pointer value that resulted from a previous array *new-expression*.<sup>83</sup> If not, the behavior is undefined. [Note: This means that the syntax of the *delete-expression* must match the type of the object allocated by `new`, not the syntax of the *new-expression*. —end note] [Note: A pointer to a `const` type can be the operand of a *delete-expression*; it is not necessary to cast away the constness (??) of the pointer expression before it is used as the operand of the *delete-expression*. —end note]
- 3 In a single-object delete expression, if the static type of the object to be deleted is different from its dynamic type, the static type shall be a base class of the dynamic type of the object to be deleted and the static type shall have a virtual destructor or the behavior is undefined. In an array delete expression, if the dynamic type of the object to be deleted differs from its static type, the behavior is undefined.
- 4 The *cast-expression* in a *delete-expression* shall be evaluated exactly once.
- 5 If the object being deleted has incomplete class type at the point of deletion and the complete class has a non-trivial destructor or a deallocation function, the behavior is undefined.
- 6 If the value of the operand of the *delete-expression* is not a null pointer value, the *delete-expression* will invoke the destructor (if any) for the object or the elements of the array being deleted. In the case of an array, the elements will be destroyed in order of decreasing address (that is, in reverse order of the completion of their constructor; see ??).
- 7 If the value of the operand of the *delete-expression* is not a null pointer value, then:
  - (7.1) — If the allocation call for the *new-expression* for the object to be deleted was not omitted and the allocation was not extended (??), the *delete-expression* shall call a deallocation function (??). The value returned from the allocation call of the *new-expression* shall be passed as the first argument to the deallocation function.
  - (7.2) — Otherwise, if the allocation was extended or was provided by extending the allocation of another *new-expression*, and the *delete-expression* for every other pointer value produced by a *new-expression* that had storage provided by the extended *new-expression* has been evaluated, the *delete-expression* shall call a deallocation function. The value returned from the allocation call of the extended *new-expression* shall be passed as the first argument to the deallocation function.
  - (7.3) — Otherwise, the *delete-expression* will not call a deallocation function.

<sup>81</sup>) A lambda expression with a *lambda-introducer* that consists of empty square brackets can follow the `delete` keyword if the lambda expression is enclosed in parentheses.

<sup>82</sup>) This implies that an object cannot be deleted using a pointer of type `void*` because `void` is not an object type.

<sup>83</sup>) For nonzero-length arrays, this is the same as a pointer to the first element of the array created by that *new-expression*. Zero-length arrays do not have a first element.

[*Note*: The deallocation function is called regardless of whether the destructor for the object or some element of the array throws an exception. — *end note*] If the value of the operand of the *delete-expression* is a null pointer value, it is unspecified whether a deallocation function will be called as described above.

- 8 [*Note*: An implementation provides default definitions of the global deallocation functions `operator delete` for non-arrays (??) and `operator delete[]` for arrays (??). A C++ program can provide alternative definitions of these functions (??), and/or class-specific versions (??). — *end note*]
- 9 When the keyword `delete` in a *delete-expression* is preceded by the unary `::` operator, the deallocation function's name is looked up in global scope. Otherwise, the lookup considers class-specific deallocation functions (??). If no class-specific deallocation function is found, the deallocation function's name is looked up in global scope.
- 10 If deallocation function lookup finds more than one usual deallocation function, the function to be called is selected as follows:
  - (10.1) — If the type has new-extended alignment, a function with a parameter of type `std::align_val_t` is preferred; otherwise a function without such a parameter is preferred. If exactly one preferred function is found, that function is selected and the selection process terminates. If more than one preferred function is found, all non-preferred functions are eliminated from further consideration.
  - (10.2) — If the deallocation functions have class scope, the one without a parameter of type `std::size_t` is selected.
  - (10.3) — If the type is complete and if, for the second alternative (delete array) only, the operand is a pointer to a class type with a non-trivial destructor or a (possibly multi-dimensional) array thereof, the function with a parameter of type `std::size_t` is selected.
  - (10.4) — Otherwise, it is unspecified whether a deallocation function with a parameter of type `std::size_t` is selected.
- 11 When a *delete-expression* is executed, the selected deallocation function shall be called with the address of the most-derived object in a single-object delete expression, or the address of the object suitably adjusted for the array allocation overhead (??) in an array delete expression, as its first argument. If a deallocation function with a parameter of type `std::align_val_t` is used, the alignment of the type of the object to be deleted is passed as the corresponding argument. If a deallocation function with a parameter of type `std::size_t` is used, the size of the most-derived type, or of the array plus allocation overhead, respectively, is passed as the corresponding argument.<sup>84</sup> [*Note*: If this results in a call to a usual deallocation function, and either the first argument was not the result of a prior call to a usual allocation function or the second argument was not the corresponding argument in said call, the behavior is undefined (??, ??). — *end note*]
- 12 Access and ambiguity control are done for both the deallocation function and the destructor (??, ??).

### 8.5.2.6 Alignof

[`expr.alignof`]

- 1 An `alignof` expression yields the alignment requirement of its operand type. The operand shall be a *type-id* representing a complete object type, or an array thereof, or a reference to one of those types.
- 2 The result is an integral constant of type `std::size_t`.
- 3 When `alignof` is applied to a reference type, the result is the alignment of the referenced type. When `alignof` is applied to an array type, the result is the alignment of the element type.

<sup>84</sup>) If the static type of the object to be deleted is complete and is different from the dynamic type, and the destructor is not virtual, the size might be incorrect, but that case is already undefined, as stated above.

### 8.5.2.7 noexcept operator

[expr.unary.noexcept]

- 1 The `noexcept` operator determines whether the evaluation of its operand, which is an unevaluated operand (??), can throw an exception (??).

*noexcept-expression:*

`noexcept ( expression )`

- 2 The result of the `noexcept` operator is a constant of type `bool` and is a prvalue.
- 3 The result of the `noexcept` operator is `true` unless the *expression* is potentially-throwing (??).

### 8.5.3 Explicit type conversion (cast notation)

[expr.cast]

- 1 The result of the expression (T) *cast-expression* is of type T. The result is an lvalue if T is an lvalue reference type or an rvalue reference to function type and an xvalue if T is an rvalue reference to object type; otherwise the result is a prvalue. [ *Note:* If T is a non-class type that is cv-qualified, the *cv-qualifiers* are discarded when determining the type of the resulting prvalue; see ??.. — *end note* ]
- 2 An explicit type conversion can be expressed using functional notation (??), a type conversion operator (`dynamic_cast`, `static_cast`, `reinterpret_cast`, `const_cast`), or the *cast* notation.

*cast-expression:*

*unary-expression*

`( type-id ) cast-expression`

- 3 Any type conversion not mentioned below and not explicitly defined by the user (??) is ill-formed.
- 4 The conversions performed by

- (4.1) — a `const_cast` (??),
- (4.2) — a `static_cast` (??),
- (4.3) — a `static_cast` followed by a `const_cast`,
- (4.4) — a `reinterpret_cast` (??), or
- (4.5) — a `reinterpret_cast` followed by a `const_cast`,

can be performed using the *cast* notation of explicit type conversion. The same semantic restrictions and behaviors apply, with the exception that in performing a `static_cast` in the following situations the conversion is valid even if the base class is inaccessible:

- (4.6) — a pointer to an object of derived class type or an lvalue or rvalue of derived class type may be explicitly converted to a pointer or reference to an unambiguous base class type, respectively;
- (4.7) — a pointer to member of derived class type may be explicitly converted to a pointer to member of an unambiguous non-virtual base class type;
- (4.8) — a pointer to an object of an unambiguous non-virtual base class type, a glvalue of an unambiguous non-virtual base class type, or a pointer to member of an unambiguous non-virtual base class type may be explicitly converted to a pointer, a reference, or a pointer to member of a derived class type, respectively.

If a conversion can be interpreted in more than one of the ways listed above, the interpretation that appears first in the list is used, even if a cast resulting from that interpretation is ill-formed. If a conversion can be interpreted in more than one way as a `static_cast` followed by a `const_cast`, the conversion is ill-formed.

[ *Example:* ]

```
struct A { };
```

```

struct I1 : A { };
struct I2 : A { };
struct D : I1, I2 { };
A* foo( D* p ) {
    return (A*)( p );           // ill-formed static_cast interpretation
}

— end example]

```

- <sup>5</sup> The operand of a cast using the cast notation can be a prvalue of type “pointer to incomplete class type”. The destination type of a cast using the cast notation can be “pointer to incomplete class type”. If both the operand and destination types are class types and one or both are incomplete, it is unspecified whether the `static_cast` or the `reinterpret_cast` interpretation is used, even if there is an inheritance relationship between the two classes. [ *Note:* For example, if the classes were defined later in the translation unit, a multi-pass compiler would be permitted to interpret a cast between pointers to the classes as if the class types were complete at the point of the cast. — end note]

#### 8.5.4 Pointer-to-member operators

[expr.mptr.oper]

- <sup>1</sup> The pointer-to-member operators `->*` and `.*` group left-to-right.

*pm-expression:*

- cast-expression*
- pm-expression .\** *cast-expression*
- pm-expression ->\** *cast-expression*

- <sup>2</sup> The binary operator `.*` binds its second operand, which shall be of type “pointer to member of T” to its first operand, which shall be a glvalue of class T or of a class of which T is an unambiguous and accessible base class. The result is an object or a function of the type specified by the second operand.
- <sup>3</sup> The binary operator `->*` binds its second operand, which shall be of type “pointer to member of T” to its first operand, which shall be of type “pointer to U” where U is either T or a class of which T is an unambiguous and accessible base class. The expression `E1->*E2` is converted into the equivalent form `(*(E1)).*E2`.
- <sup>4</sup> Abbreviating *pm-expression .\** *cast-expression* as `E1.*E2`, E1 is called the *object expression*. If the dynamic type of E1 does not contain the member to which E2 refers, the behavior is undefined. Otherwise, the expression E1 is sequenced before the expression E2.
- <sup>5</sup> The restrictions on *cv*-qualification, and the manner in which the *cv*-qualifiers of the operands are combined to produce the *cv*-qualifiers of the result, are the same as the rules for `E1.E2` given in [??](#). [ *Note:* It is not possible to use a pointer to member that refers to a `mutable` member to modify a `const` class object. For example,

```

struct S {
    S() : i(0) { }
    mutable int i;
};
void f()
{
    const S cs;
    int S::* pm = &S::i;           // pm refers to mutable member S::i
    cs.*pm = 88;                  // ill-formed: cs is a const object
}

— end note]

```

- <sup>6</sup> If the result of `.*` or `->*` is a function, then that result can be used only as the operand for the function call operator `()`. [Example:

```
(ptr_to_obj->*ptr_to_mfct)(10);
```

calls the member function denoted by `ptr_to_mfct` for the object pointed to by `ptr_to_obj`. —end example]

In a `.*` expression whose object expression is an rvalue, the program is ill-formed if the second operand is a pointer to member function whose *ref-qualifier* is `&`, unless its *cv-qualifier-seq* is `const`. In a `.*` expression whose object expression is an lvalue, the program is ill-formed if the second operand is a pointer to member function whose *ref-qualifier* is `&&`. The result of a `.*` expression whose second operand is a pointer to a data member is an lvalue if the first operand is an lvalue and an xvalue otherwise. The result of a `.*` expression whose second operand is a pointer to a member function is a prvalue. If the second operand is the null member pointer value (??), the behavior is undefined.

### 8.5.5 Multiplicative operators

[expr.mul]

- <sup>1</sup> The multiplicative operators `*`, `/`, and `%` group left-to-right.

*multiplicative-expression:*

```
pm-expression
multiplicative-expression * pm-expression
multiplicative-expression / pm-expression
multiplicative-expression % pm-expression
```

- <sup>2</sup> The operands of `*` and `/` shall have arithmetic or unscoped enumeration type; the operands of `%` shall have integral or unscoped enumeration type. The usual arithmetic conversions (??) are performed on the operands and determine the type of the result.
- <sup>3</sup> The binary `*` operator indicates multiplication.
- <sup>4</sup> The binary `/` operator yields the quotient, and the binary `%` operator yields the remainder from the division of the first expression by the second. If the second operand of `/` or `%` is zero the behavior is undefined. For integral operands the `/` operator yields the algebraic quotient with any fractional part discarded;<sup>85</sup> if the quotient `a/b` is representable in the type of the result, `(a/b)*b + a%b` is equal to `a`; otherwise, the behavior of both `a/b` and `a%b` is undefined.

### 8.5.6 Additive operators

[expr.add]

- <sup>1</sup> The additive operators `+` and `-` group left-to-right. The usual arithmetic conversions (??) are performed for operands of arithmetic or enumeration type.

*additive-expression:*

```
multiplicative-expression
additive-expression + multiplicative-expression
additive-expression - multiplicative-expression
```

For addition, either both operands shall have arithmetic or unscoped enumeration type, or one operand shall be a pointer to a completely-defined object type and the other shall have integral or unscoped enumeration type.

- <sup>2</sup> For subtraction, one of the following shall hold:

- (2.1) — both operands have arithmetic or unscoped enumeration type; or

---

<sup>85</sup>) This is often called truncation towards zero.

- (2.2) — both operands are pointers to cv-qualified or cv-unqualified versions of the same completely-defined object type; or
  - (2.3) — the left operand is a pointer to a completely-defined object type and the right operand has integral or unscoped enumeration type.
- 3 The result of the binary `+` operator is the sum of the operands. The result of the binary `-` operator is the difference resulting from the subtraction of the second operand from the first.
- 4 When an expression that has integral type is added to or subtracted from a pointer, the result has the type of the pointer operand. If the expression `P` points to element `x[i]` of an array object `x` with `n` elements,<sup>86</sup> the expressions `P + J` and `J + P` (where `J` has the value `j`) point to the (possibly-hypothetical) element `x[i + j]` if  $0 \leq i + j \leq n$ ; otherwise, the behavior is undefined. Likewise, the expression `P - J` points to the (possibly-hypothetical) element `x[i - j]` if  $0 \leq i - j \leq n$ ; otherwise, the behavior is undefined.
- 5 When two pointers to elements of the same array object are subtracted, the type of the result is an implementation-defined signed integral type; this type shall be the same type that is defined as `std::ptrdiff_t` in the `<cstddef>` header (??). If the expressions `P` and `Q` point to, respectively, elements `x[i]` and `x[j]` of the same array object `x`, the expression `P - Q` has the value `i - j`; otherwise, the behavior is undefined. [Note: If the value `i - j` is not in the range of representable values of type `std::ptrdiff_t`, the behavior is undefined. —end note]
- 6 For addition or subtraction, if the expressions `P` or `Q` have type “pointer to *cv T*”, where `T` and the array element type are not similar (??), the behavior is undefined. [Note: In particular, a pointer to a base class cannot be used for pointer arithmetic when the array contains objects of a derived class type. —end note]
- 7 If the value 0 is added to or subtracted from a null pointer value, the result is a null pointer value. If two null pointer values are subtracted, the result compares equal to the value 0 converted to the type `std::ptrdiff_t`.

### 8.5.7 Shift operators

[`expr.shift`]

- 1 The shift operators `<<` and `>>` group left-to-right.

```

shift-expression:
  additive-expression
  shift-expression << additive-expression
  shift-expression >> additive-expression

```

The operands shall be of integral or unscoped enumeration type and integral promotions are performed. The type of the result is that of the promoted left operand. The behavior is undefined if the right operand is negative, or greater than or equal to the length in bits of the promoted left operand.

- 2 The value of `E1 << E2` is `E1` left-shifted `E2` bit positions; vacated bits are zero-filled. If `E1` has an unsigned type, the value of the result is  $E1 \times 2^{E2}$ , reduced modulo one more than the maximum value representable in the result type. Otherwise, if `E1` has a signed type and non-negative value, and  $E1 \times 2^{E2}$  is representable in the corresponding unsigned type of the result type, then that value, converted to the result type, is the resulting value; otherwise, the behavior is undefined.
- 3 The value of `E1 >> E2` is `E1` right-shifted `E2` bit positions. If `E1` has an unsigned type or if `E1` has a signed type and a non-negative value, the value of the result is the integral part of the quotient of  $E1/2^{E2}$ . If `E1` has a signed type and a negative value, the resulting value is implementation-defined.

<sup>86)</sup> An object that is not an array element is considered to belong to a single-element array for this purpose; see ???. A pointer past the last element of an array `x` of `n` elements is considered to be equivalent to a pointer to a hypothetical element `x[n]` for this purpose; see ???.

- <sup>4</sup> The expression E1 is sequenced before the expression E2.

### 8.5.8 Three-way comparison operator

[expr.spaceShip]

- <sup>1</sup> The three-way comparison operator groups left-to-right.

*compare-expression:*

*shift-expression*

*compare-expression* <=> *shift-expression*

- <sup>2</sup> The expression p <=> q is a prvalue indicating whether p is less than, equal to, greater than, or incomparable with q.

- <sup>3</sup> If one of the operands is of type `bool` and the other is not, the program is ill-formed.

- <sup>4</sup> If both operands have arithmetic types, the usual arithmetic conversions (??) are applied to the operands. Then:

- (4.1) — If a narrowing conversion (??) is required, other than from an integral type to a floating point type, the program is ill-formed.

- (4.2) — Otherwise, if the operands have integral type, the result is of type `std::strong_ordering`. The result is `std::strong_ordering::equal` if both operands are arithmetically equal, `std::strong_ordering::less` if the first operand is arithmetically less than the second operand, and `std::strong_ordering::greater` otherwise.

- (4.3) — Otherwise, the operands have floating-point type, and the result is of type `std::partial_ordering`. The expression a <=> b yields `std::partial_ordering::less` if a is less than b, `std::partial_ordering::greater` if a is greater than b, `std::partial_ordering::equivalent` if a is equivalent to b, and `std::partial_ordering::unordered` otherwise.

- <sup>5</sup> If both operands have the same enumeration type E, the operator yields the result of converting the operands to the underlying type of E and applying <=> to the converted operands.

- <sup>6</sup> If at least one of the operands is of pointer type, array-to-pointer conversions (??), pointer conversions (??), function pointer conversions (??), and qualification conversions (??) are performed on both operands to bring them to their composite pointer type (??). If at least one of the operands is of pointer-to-member type, pointer-to-member conversions (??) and qualification conversions (??) are performed on both operands to bring them to their composite pointer type (??). If both operands are null pointer constants, but not both of integer type, pointer conversions (??) are performed on both operands to bring them to their composite pointer type (??). In all cases, after the conversions, the operands shall have the same type. [ Note: If both of the operands are arrays, array-to-pointer conversions (??) are not applied. — end note ]

- <sup>7</sup> If the composite pointer type is a function pointer type, a pointer-to-member type, or `std::nullptr_t`, the result is of type `std::strong_equality`; the result is `std::strong_equality::equal` if the (possibly converted) operands compare equal (??) and `std::strong_equality::unequal` if they compare unequal, otherwise the result of the operator is unspecified.

- <sup>8</sup> If the composite pointer type is an object pointer type, p <=> q is of type `std::strong_ordering`. If two pointer operands p and q compare equal (??), p <=> q yields `std::strong_ordering::equal`; if p and q compare unequal, p <=> q yields `std::strong_ordering::less` if q compares greater than p and `std::strong_ordering::greater` if p compares greater than q (??). Otherwise, the result is unspecified.

- <sup>9</sup> Otherwise, the program is ill-formed.

- <sup>10</sup> The five comparison category types (??) (the types `std::strong_ordering`, `std::strong_equality`, `std::weak_ordering`, `std::weak_equality`, and `std::partial_ordering`) are not predefined; if the header `<compare>` is not included prior to a use of such a class type – even an implicit use in which the type is not named (e.g., via the `auto` specifier (??)) in a defaulted three-way comparison (??) or use of the built-in operator) – the program is ill-formed.

### 8.5.9 Relational operators

[expr.rel]

- <sup>1</sup> The relational operators group left-to-right. [ *Example*: `a < b < c` means `(a < b) < c` and *not* `(a < b) && (b < c)`. — *end example* ]

*relational-expression*:

```
compare-expression
relational-expression < compare-expression
relational-expression > compare-expression
relational-expression <= compare-expression
relational-expression >= compare-expression
```

The operands shall have arithmetic, enumeration, or pointer type. The operators `<` (less than), `>` (greater than), `<=` (less than or equal to), and `>=` (greater than or equal to) all yield `false` or `true`. The type of the result is `bool`.

- <sup>2</sup> The usual arithmetic conversions (??) are performed on operands of arithmetic or enumeration type. If both operands are pointers, pointer conversions (??) and qualification conversions (??) are performed to bring them to their composite pointer type (??). After conversions, the operands shall have the same type.
- <sup>3</sup> Comparing unequal pointers to objects<sup>87</sup> is defined as follows:
- (3.1) — If two pointers point to different elements of the same array, or to subobjects thereof, the pointer to the element with the higher subscript compares greater.
  - (3.2) — If two pointers point to different non-static data members of the same object, or to subobjects of such members, recursively, the pointer to the later declared member compares greater provided the two members have the same access control (??) and provided their class is not a union.
  - (3.3) — Otherwise, neither pointer compares greater than the other.
- <sup>4</sup> If two operands `p` and `q` compare equal (??), `p <= q` and `p >= q` both yield `true` and `p < q` and `p > q` both yield `false`. Otherwise, if a pointer `p` compares greater than a pointer `q`, `p >= q`, `p > q`, `q <= p`, and `q < p` all yield `true` and `p <= q`, `p < q`, `q >= p`, and `q > p` all yield `false`. Otherwise, the result of each of the operators is unspecified.
- <sup>5</sup> If both operands (after conversions) are of arithmetic or enumeration type, each of the operators shall yield `true` if the specified relationship is true and `false` if it is false.

### 8.5.10 Equality operators

[expr.eq]

*equality-expression*:

```
relational-expression
equality-expression == relational-expression
equality-expression != relational-expression
```

- <sup>1</sup> The `==` (equal to) and the `!=` (not equal to) operators group left-to-right. The operands shall have arithmetic, enumeration, pointer, or pointer-to-member type, or type `std::nullptr_t`. The operators `==` and `!=` both

<sup>87</sup>) An object that is not an array element is considered to belong to a single-element array for this purpose; see ???. A pointer past the last element of an array `x` of  $n$  elements is considered to be equivalent to a pointer to a hypothetical element `x[n]` for this purpose; see ???.

yield `true` or `false`, i.e., a result of type `bool`. In each case below, the operands shall have the same type after the specified conversions have been applied.

- 2 If at least one of the operands is a pointer, pointer conversions (??), function pointer conversions (??), and qualification conversions (??) are performed on both operands to bring them to their composite pointer type (??). Comparing pointers is defined as follows:

- (2.1) — If one pointer represents the address of a complete object, and another pointer represents the address one past the last element of a different complete object,<sup>88</sup> the result of the comparison is unspecified.
- (2.2) — Otherwise, if the pointers are both null, both point to the same function, or both represent the same address (??), they compare equal.
- (2.3) — Otherwise, the pointers compare unequal.

- 3 If at least one of the operands is a pointer to member, pointer-to-member conversions (??) and qualification conversions (??) are performed on both operands to bring them to their composite pointer type (??). Comparing pointers to members is defined as follows:

- (3.1) — If two pointers to members are both the null member pointer value, they compare equal.
- (3.2) — If only one of two pointers to members is the null member pointer value, they compare unequal.
- (3.3) — If either is a pointer to a virtual member function, the result is unspecified.
- (3.4) — If one refers to a member of class `C1` and the other refers to a member of a different class `C2`, where neither is a base class of the other, the result is unspecified. [ *Example*:

```
struct A {};
struct B : A { int x; };
struct C : A { int x; };

int A::*bx = (int(A::*))&B::x;
int A::*cx = (int(A::*))&C::x;

bool b1 = (bx == cx); // unspecified
— end example ]
```

- (3.5) — If both refer to (possibly different) members of the same union (??), they compare equal.
- (3.6) — Otherwise, two pointers to members compare equal if they would refer to the same member of the same most derived object (??) or the same subobject if indirection with a hypothetical object of the associated class type were performed, otherwise they compare unequal. [ *Example*:

```
struct B {
    int f();
};

struct L : B {};
struct R : B {};
struct D : L, R {};

int (B::*pb)() = &B::f;
int (L::*pl)() = pb;
int (R::*pr)() = pb;
int (D::*pd1)() = pl;
```

---

<sup>88</sup>) An object that is not an array element is considered to belong to a single-element array for this purpose; see ??.

```

int (D::*pdr)() = pr;
bool x = (pd1 == pdr);           // false
bool y = (pb == pl);           // true
— end example]

```

- 4 Two operands of type `std::nullptr_t` or one operand of type `std::nullptr_t` and the other a null pointer constant compare equal.
- 5 If two operands compare equal, the result is `true` for the `==` operator and `false` for the `!=` operator. If two operands compare unequal, the result is `false` for the `==` operator and `true` for the `!=` operator. Otherwise, the result of each of the operators is unspecified.
- 6 If both operands are of arithmetic or enumeration type, the usual arithmetic conversions (??) are performed on both operands; each of the operators shall yield `true` if the specified relationship is true and `false` if it is false.

### 8.5.11 Bitwise AND operator

[expr.bit.and]

*and-expression:*

*equality-expression*

*and-expression & equality-expression*

- 1 The usual arithmetic conversions (??) are performed; the result is the bitwise AND function of the operands. The operator applies only to integral or unscoped enumeration operands.

### 8.5.12 Bitwise exclusive OR operator

[expr.xor]

*exclusive-or-expression:*

*and-expression*

*exclusive-or-expression ^ and-expression*

- 1 The usual arithmetic conversions (??) are performed; the result is the bitwise exclusive OR function of the operands. The operator applies only to integral or unscoped enumeration operands.

### 8.5.13 Bitwise inclusive OR operator

[expr.or]

*inclusive-or-expression:*

*exclusive-or-expression*

*inclusive-or-expression | exclusive-or-expression*

- 1 The usual arithmetic conversions (??) are performed; the result is the bitwise inclusive OR function of its operands. The operator applies only to integral or unscoped enumeration operands.

### 8.5.14 Logical AND operator

[expr.log.and]

*logical-and-expression:*

*inclusive-or-expression*

*logical-and-expression && inclusive-or-expression*

- 1 The `&&` operator groups left-to-right. The operands are both contextually converted to `bool` (??). The result is `true` if both operands are `true` and `false` otherwise. Unlike `&`, `&&` guarantees left-to-right evaluation: the second operand is not evaluated if the first operand is `false`.
- 2 The result is a `bool`. If the second expression is evaluated, every value computation and side effect associated with the first expression is sequenced before every value computation and side effect associated with the second expression.

### 8.5.15 Logical OR operator

[expr.log.or]

*logical-or-expression:*

*logical-and-expression*

*logical-or-expression || logical-and-expression*

- 1 The `||` operator groups left-to-right. The operands are both contextually converted to `bool` (??). The result is `true` if either of its operands is `true`, and `false` otherwise. Unlike `|`, `||` guarantees left-to-right evaluation; moreover, the second operand is not evaluated if the first operand evaluates to `true`.
- 2 The result is a `bool`. If the second expression is evaluated, every value computation and side effect associated with the first expression is sequenced before every value computation and side effect associated with the second expression.

### 8.5.16 Conditional operator

[expr.cond]

*conditional-expression:*

*logical-or-expression*

*logical-or-expression ? expression : assignment-expression*

- 1 Conditional expressions group right-to-left. The first expression is contextually converted to `bool` (??). It is evaluated and if it is `true`, the result of the conditional expression is the value of the second expression, otherwise that of the third expression. Only one of the second and third expressions is evaluated. Every value computation and side effect associated with the first expression is sequenced before every value computation and side effect associated with the second or third expression.
- 2 If either the second or the third operand has type `void`, one of the following shall hold:
  - (2.1) — The second or the third operand (but not both) is a (possibly parenthesized) *throw-expression* (??); the result is of the type and value category of the other. The *conditional-expression* is a bit-field if that operand is a bit-field.
  - (2.2) — Both the second and the third operands have type `void`; the result is of type `void` and is a prvalue. [Note: This includes the case where both operands are *throw-expressions*. — end note]
- 3 Otherwise, if the second and third operand are glvalue bit-fields of the same value category and of types *cv1 T* and *cv2 T*, respectively, the operands are considered to be of type *cv T* for the remainder of this subclause, where *cv* is the union of *cv1* and *cv2*.
- 4 Otherwise, if the second and third operand have different types and either has (possibly cv-qualified) class type, or if both are glvalues of the same value category and the same type except for cv-qualification, an attempt is made to form an implicit conversion sequence (??) from each of those operands to the type of the other. [Note: Properties such as access, whether an operand is a bit-field, or whether a conversion function is deleted are ignored for that determination. — end note] Attempts are made to form an implicit conversion sequence from an operand expression *E1* of type *T1* to a target type related to the type *T2* of the operand expression *E2* as follows:
  - (4.1) — If *E2* is an lvalue, the target type is “lvalue reference to *T2*”, subject to the constraint that in the conversion the reference must bind directly (??) to an lvalue.
  - (4.2) — If *E2* is an xvalue, the target type is “rvalue reference to *T2*”, subject to the constraint that the reference must bind directly.
  - (4.3) — If *E2* is a prvalue or if neither of the conversion sequences above can be formed and at least one of the operands has (possibly cv-qualified) class type:

- (4.3.1) — if T1 and T2 are the same class type (ignoring cv-qualification), or one is a base class of the other, and T2 is at least as cv-qualified as T1, the target type is T2,
- (4.3.2) — otherwise, the target type is the type that E2 would have after applying the lvalue-to-rvalue (??), array-to-pointer (??), and function-to-pointer (??) standard conversions.

Using this process, it is determined whether an implicit conversion sequence can be formed from the second operand to the target type determined for the third operand, and vice versa. If both sequences can be formed, or one can be formed but it is the ambiguous conversion sequence, the program is ill-formed. If no conversion sequence can be formed, the operands are left unchanged and further checking is performed as described below. Otherwise, if exactly one conversion sequence can be formed, that conversion is applied to the chosen operand and the converted operand is used in place of the original operand for the remainder of this subclause. [Note: The conversion might be ill-formed even if an implicit conversion sequence could be formed. —end note]

- <sup>5</sup> If the second and third operands are glvalues of the same value category and have the same type, the result is of that type and value category and it is a bit-field if the second or the third operand is a bit-field, or if both are bit-fields.
- <sup>6</sup> Otherwise, the result is a prvalue. If the second and third operands do not have the same type, and either has (possibly cv-qualified) class type, overload resolution is used to determine the conversions (if any) to be applied to the operands (??, ??). If the overload resolution fails, the program is ill-formed. Otherwise, the conversions thus determined are applied, and the converted operands are used in place of the original operands for the remainder of this subclause.
- <sup>7</sup> Lvalue-to-rvalue (??), array-to-pointer (??), and function-to-pointer (??) standard conversions are performed on the second and third operands. After those conversions, one of the following shall hold:
  - (7.1) — The second and third operands have the same type; the result is of that type and the result object is initialized using the selected operand.
  - (7.2) — The second and third operands have arithmetic or enumeration type; the usual arithmetic conversions (??) are performed to bring them to a common type, and the result is of that type.
  - (7.3) — One or both of the second and third operands have pointer type; pointer conversions (??), function pointer conversions (??), and qualification conversions (??) are performed to bring them to their composite pointer type (??). The result is of the composite pointer type.
  - (7.4) — One or both of the second and third operands have pointer-to-member type; pointer to member conversions (??) and qualification conversions (??) are performed to bring them to their composite pointer type (??). The result is of the composite pointer type.
  - (7.5) — Both the second and third operands have type `std::nullptr_t` or one has that type and the other is a null pointer constant. The result is of type `std::nullptr_t`.

### 8.5.17 Throwing an exception

[expr.throw]

*throw-expression:*

`throw` *assignment-expression<sub>opt</sub>*

- <sup>1</sup> A *throw-expression* is of type `void`.
- <sup>2</sup> Evaluating a *throw-expression* with an operand throws an exception (??); the type of the exception object is determined by removing any top-level *cv-qualifiers* from the static type of the operand and adjusting the type from “array of T” or function type T to “pointer to T”.

- <sup>3</sup> A *throw-expression* with no operand rethrows the currently handled exception (??). The exception is reactivated with the existing exception object; no new exception object is created. The exception is no longer considered to be caught. [Example: Code that must be executed because of an exception, but cannot completely handle the exception itself, can be written like this:

```
try {
    // ...
} catch (...) {      // catch all exceptions
    // respond (partially) to exception
    throw;           // pass the exception to some other handler
}
```

— end example]

- <sup>4</sup> If no exception is presently being handled, evaluating a *throw-expression* with no operand calls `std::terminate()` (??).

### 8.5.18 Assignment and compound assignment operators

[expr.ass]

- <sup>1</sup> The assignment operator (=) and the compound assignment operators all group right-to-left. All require a modifiable lvalue as their left operand; their result is an lvalue referring to the left operand. The result in all cases is a bit-field if the left operand is a bit-field. In all cases, the assignment is sequenced after the value computation of the right and left operands, and before the value computation of the assignment expression. The right operand is sequenced before the left operand. With respect to an indeterminately-sequenced function call, the operation of a compound assignment is a single evaluation. [Note: Therefore, a function call shall not intervene between the lvalue-to-rvalue conversion and the side effect associated with any single compound assignment operator. — end note]

*assignment-expression:*  
*conditional-expression*  
*logical-or-expression assignment-operator initializer-clause*  
*throw-expression*

*assignment-operator:* one of  
`= *= /= %= += -= >>= <<= &= ^= |=`

- <sup>2</sup> In simple assignment (=), the value of the expression replaces that of the object referred to by the left operand.
- <sup>3</sup> If the left operand is not of class type, the expression is implicitly converted (??) to the cv-unqualified type of the left operand.
- <sup>4</sup> If the left operand is of class type, the class shall be complete. Assignment to objects of a class is defined by the copy/move assignment operator (??, ??).
- <sup>5</sup> [Note: For class objects, assignment is not in general the same as initialization (??, ??, ??, ??). — end note]
- <sup>6</sup> When the left operand of an assignment operator is a bit-field that cannot represent the value of the expression, the resulting value of the bit-field is implementation-defined.
- <sup>7</sup> The behavior of an expression of the form `E1 op= E2` is equivalent to `E1 = E1 op E2` except that `E1` is evaluated only once. In `+=` and `-=`, `E1` shall either have arithmetic type or be a pointer to a possibly cv-qualified completely-defined object type. In all other cases, `E1` shall have arithmetic type.

<sup>8</sup> If the value being stored in an object is read via another object that overlaps in any way the storage of the first object, then the overlap shall be exact and the two objects shall have the same type, otherwise the behavior is undefined. [ *Note:* This restriction applies to the relationship between the left and right sides of the assignment operation; it is not a statement about how the target of the assignment may be aliased in general. See [??.](#) — *end note* ]

<sup>9</sup> A *braced-init-list* may appear on the right-hand side of

- (9.1) — an assignment to a scalar, in which case the initializer list shall have at most a single element. The meaning of  $x = \{v\}$ , where T is the scalar type of the expression x, is that of  $x = T\{v\}$ . The meaning of  $x = \{\}$  is  $x = T\{\}$ .
- (9.2) — an assignment to an object of class type, in which case the initializer list is passed as the argument to the assignment operator function selected by overload resolution ([??](#), [??](#)).

[ *Example:*

```
complex<double> z;
z = { 1,2 };           // meaning z.operator=({1,2})
z += { 1, 2 };        // meaning z.operator+=(1,2)
int a, b;
a = b = { 1 };        // meaning a=b=1;
a = { 1 } = b;         // syntax error
```

— *end example* ]

### 8.5.19 Comma operator

[expr.comma]

<sup>1</sup> The comma operator groups left-to-right.

*expression:*

*assignment-expression*

*expression , assignment-expression*

A pair of expressions separated by a comma is evaluated left-to-right; the left expression is a discarded-value expression ([??](#)). Every value computation and side effect associated with the left expression is sequenced before every value computation and side effect associated with the right expression. The type and value of the result are the type and value of the right operand; the result is of the same value category as its right operand, and is a bit-field if its right operand is a bit-field. If the right operand is a temporary expression ([??](#)), the result is a temporary expression.

<sup>2</sup> In contexts where comma is given a special meaning, [ *Example:* in lists of arguments to functions ([??](#)) and lists of initializers ([??](#)) — *end example* ] the comma operator as described in this subclause can appear only in parentheses. [ *Example:*

```
f(a, (t=3, t+2), c);
```

has three arguments, the second of which has the value 5. — *end example* ]

### 8.6 Constant expressions

[expr.const]

<sup>1</sup> Certain contexts require expressions that satisfy additional requirements as detailed in this subclause; other contexts have different semantics depending on whether or not an expression satisfies these requirements. Expressions that satisfy these requirements, assuming that copy elision is performed, are called *constant expressions*. [ *Note:* Constant expressions can be evaluated during translation. — *end note* ]

*constant-expression:*

*conditional-expression*

- <sup>2</sup> An expression **e** is a *core constant expression* unless the evaluation of **e**, following the rules of the abstract machine (??), would evaluate one of the following expressions:

- (2.1) — **this** (??), except in a `constexpr` function or a `constexpr` constructor that is being evaluated as part of **e**;
- (2.2) — an invocation of a function other than a `constexpr` constructor for a literal class, a `constexpr` function, or an implicit invocation of a trivial destructor (??) [ *Note*: Overload resolution (??) is applied as usual — *end note* ] ;
- (2.3) — an invocation of an undefined `constexpr` function or an undefined `constexpr` constructor;
- (2.4) — an invocation of an instantiated `constexpr` function or `constexpr` constructor that fails to satisfy the requirements for a `constexpr` function or `constexpr` constructor (??);
- (2.5) — an expression that would exceed the implementation-defined limits (see ??);
- (2.6) — an operation that would have undefined behavior as specified in ?? through ?? of this document [ *Note*: including, for example, signed integer overflow (??), certain pointer arithmetic (??), division by zero (??), or certain shift operations (??) — *end note* ] ;
- (2.7) — an lvalue-to-rvalue conversion (??) unless it is applied to
  - (2.7.1) — a non-volatile glvalue of integral or enumeration type that refers to a complete non-volatile `const` object with a preceding initialization, initialized with a constant expression, or
  - (2.7.2) — a non-volatile glvalue that refers to a subobject of a string literal (??), or
  - (2.7.3) — a non-volatile glvalue that refers to a non-volatile object defined with `constexpr`, or that refers to a non-mutable subobject of such an object, or
  - (2.7.4) — a non-volatile glvalue of literal type that refers to a non-volatile object whose lifetime began within the evaluation of **e**;
- (2.8) — an lvalue-to-rvalue conversion (??) that is applied to a glvalue that refers to a non-active member of a union or a subobject thereof;
- (2.9) — an invocation of an implicitly-defined copy/move constructor or copy/move assignment operator for a union whose active member (if any) is mutable, unless the lifetime of the union object began within the evaluation of **e**;
- (2.10) — an assignment expression (??) or invocation of an assignment operator (??) that would change the active member of a union;
- (2.11) — an *id-expression* that refers to a variable or data member of reference type unless the reference has a preceding initialization and either
  - (2.11.1) — it is initialized with a constant expression or
  - (2.11.2) — its lifetime began within the evaluation of **e**;
- (2.12) — in a *lambda-expression*, a reference to **this** or to a variable with automatic storage duration defined outside that *lambda-expression*, where the reference would be an odr-use (??, ??); [ *Example*:

```
void g() {
    const int n = 0;
```

```
[=] {
    constexpr int i = n; // OK, n is not odr-used and not captured here
    constexpr int j = *&n; // ill-formed, &n would be an odr-use of n
};
```

— end example] [Note: If the odr-use occurs in an invocation of a function call operator of a closure type, it no longer refers to `this` or to an enclosing automatic variable due to the transformation (??) of the *id-expression* into an access of the corresponding data member. [Example:

```
auto monad = [](auto v) { return [=] { return v; }; };
auto bind = [](auto m) {
    return [=](auto fvm) { return fvm(m()); };
};
```

// OK to have captures to automatic objects created during constant expression evaluation.
static\_assert(bind(monad(2))(monad)() == monad(2)());

— end example] — end note]

- (2.13) — a conversion from type `cv void*` to a pointer-to-object type;
- (2.14) — a dynamic cast (??);
- (2.15) — a `reinterpret_cast` (??);
- (2.16) — a pseudo-destructor call (??);
- (2.17) — modification of an object (??, ??, ??) unless it is applied to a non-volatile lvalue of literal type that refers to a non-volatile object whose lifetime began within the evaluation of `e`;
- (2.18) — a typeid expression (??) whose operand is a glvalue of a polymorphic class type;
- (2.19) — a *new-expression* (??);
- (2.20) — a *delete-expression* (??);
- (2.21) — a three-way comparison (??) comparing pointers that do not point to the same complete object or to any subobject thereof;
- (2.22) — a relational (??) or equality (??) operator where the result is unspecified; or
- (2.23) — a *throw-expression* (??).

If `e` satisfies the constraints of a core constant expression, but evaluation of `e` would evaluate an operation that has undefined behavior as specified in ?? through ?? of this document, it is unspecified whether `e` is a core constant expression.

[Example:

```
int x; // not constant
struct A {
    constexpr A(bool b) : m(b?42:x) { }
    int m;
};
constexpr int v = A(true).m; // OK: constructor call initializes m with the value 42
constexpr int w = A(false).m; // error: initializer for m is x, which is non-constant
```

```

constexpr int f1(int k) {
    constexpr int x = k;           // error: x is not initialized by a constant expression
                                    // because lifetime of k began outside the initializer of x
    return x;
}

constexpr int f2(int k) {
    int x = k;                   // OK: not required to be a constant expression
                                    // because x is not constexpr
    return x;
}

constexpr int incr(int &n) {
    return ++n;
}

constexpr int g(int k) {
    constexpr int x = incr(k);   // error: incr(k) is not a core constant expression
                                    // because lifetime of k began outside the expression incr(k)
    return x;
}

constexpr int h(int k) {
    int x = incr(k);           // OK: incr(k) is not required to be a core constant expression
    return x;
}

constexpr int y = h(1);        // OK: initializes y with the value 2
                            // h(1) is a core constant expression because
                            // the lifetime of k begins inside h(1)

```

— end example]

- <sup>3</sup> An *integral constant expression* is an expression of integral or unscoped enumeration type, implicitly converted to a prvalue, where the converted expression is a core constant expression. [ *Note:* Such expressions may be used as bit-field lengths (??), as enumerator initializers if the underlying type is not fixed (??), and as alignments (??). — end note]
- <sup>4</sup> If an expression of literal class type is used in a context where an integral constant expression is required, then that expression is contextually implicitly converted (??) to an integral or unscoped enumeration type and the selected conversion function shall be `constexpr`. [ *Example:*

```

struct A {
    constexpr A(int i) : val(i) { }
    constexpr operator int() const { return val; }
    constexpr operator long() const { return 42; }

private:
    int val;
};

template<int> struct X {};
constexpr A a = alignof(int);
alignas(a) int n;           // error: ambiguous conversion
struct B { int n : a; };    // error: ambiguous conversion

```

— end example]

<sup>5</sup> A *converted constant expression* of type T is an expression, implicitly converted to type T, where the converted expression is a constant expression and the implicit conversion sequence contains only

- (5.1) — user-defined conversions,
- (5.2) — lvalue-to-rvalue conversions (??),
- (5.3) — array-to-pointer conversions (??),
- (5.4) — function-to-pointer conversions (??),
- (5.5) — qualification conversions (??),
- (5.6) — integral promotions (??),
- (5.7) — integral conversions (??) other than narrowing conversions (??),
- (5.8) — null pointer conversions (??) from `std::nullptr_t`,
- (5.9) — null member pointer conversions (??) from `std::nullptr_t`, and
- (5.10) — function pointer conversions (??),

and where the reference binding (if any) binds directly. [Note: Such expressions may be used in `new` expressions (??), as case expressions (??), as enumerator initializers if the underlying type is fixed (??), as array bounds (??), and as non-type template arguments (??). —end note] A *contextually converted constant expression of type bool* is an expression, contextually converted to `bool` (??), where the converted expression is a constant expression and the conversion sequence contains only the conversions above.

<sup>6</sup> A *constant expression* is either a glvalue core constant expression that refers to an entity that is a permitted result of a constant expression (as defined below), or a prvalue core constant expression whose value satisfies the following constraints:

- (6.1) — if the value is an object of class type, each non-static data member of reference type refers to an entity that is a permitted result of a constant expression,
- (6.2) — if the value is of pointer type, it contains the address of an object with static storage duration, the address past the end of such an object (??), the address of a function, or a null pointer value, and
- (6.3) — if the value is an object of class or array type, each subobject satisfies these constraints for the value.

An entity is a *permitted result of a constant expression* if it is an object with static storage duration that is either not a temporary object or is a temporary object whose value satisfies the above constraints, or it is a function.

<sup>7</sup> [Note: Since this document imposes no restrictions on the accuracy of floating-point operations, it is unspecified whether the evaluation of a floating-point expression during translation yields the same result as the evaluation of the same expression (or the same operations on the same values) during program execution.<sup>89</sup> [Example:

```
bool f() {
    char array[1 + int(1 + 0.2 - 0.1 - 0.1)]; // Must be evaluated during translation
    int size = 1 + int(1 + 0.2 - 0.1 - 0.1); // May be evaluated at runtime
    return sizeof(array) == size;
}
```

It is unspecified whether the value of `f()` will be `true` or `false`. —end example] —end note]

---

<sup>89</sup>) Nonetheless, implementations should provide consistent results, irrespective of whether the evaluation was performed during translation and/or during program execution.

<sup>8</sup> An expression is *potentially constant evaluated* if it is:

- (8.1) — a potentially-evaluated expression (??),
- (8.2) — a *constraint-expression*, including one formed from the *constraint-logical-or-expression* of a *requires-clause*,
- (8.3) — an immediate subexpression of a *braced-init-list*,<sup>90</sup>
- (8.4) — an expression of the form & *cast-expression* that occurs within a templated entity,<sup>91</sup> or
- (8.5) — a subexpression of one of the above that is not a subexpression of a nested unevaluated operand.

A function or variable is *needed for constant evaluation* if it is:

- (8.6) — a *constexpr* function that is named by an expression (??) that is potentially constant evaluated, or
- (8.7) — a variable whose name appears as a potentially constant evaluated expression that is either a *constexpr* variable or is of non-volatile const-qualified integral type or of reference type.

---

<sup>90</sup>) Constant evaluation may be necessary to determine whether a narrowing conversion is performed (??).

<sup>91</sup>) Constant evaluation may be necessary to determine whether such an expression is value-dependent (??).

## 9 Statements

[stmt.stmt]

- <sup>1</sup> Except as indicated, statements are executed in sequence.

*statement:*

- labeled-statement*
- attribute-specifier-seq<sub>opt</sub>* *expression-statement*
- attribute-specifier-seq<sub>opt</sub>* *compound-statement*
- attribute-specifier-seq<sub>opt</sub>* *selection-statement*
- attribute-specifier-seq<sub>opt</sub>* *iteration-statement*
- attribute-specifier-seq<sub>opt</sub>* *jump-statement*
- declaration-statement*
- attribute-specifier-seq<sub>opt</sub>* *try-block*

*init-statement:*

- expression-statement*
- simple-declaration*

*condition:*

- expression*
- attribute-specifier-seq<sub>opt</sub>* *decl-specifier-seq* *declarator* *brace-or-equal-initializer*

The optional *attribute-specifier-seq* appertains to the respective statement.

- <sup>2</sup> The rules for *conditions* apply both to *selection-statements* and to the **for** and **while** statements (??). The *declarator* shall not specify a function or an array. The *decl-specifier-seq* shall not define a class or enumeration. If the **auto** *type-specifier* appears in the *decl-specifier-seq*, the type of the identifier being declared is deduced from the initializer as described in ??.
- <sup>3</sup> A name introduced by a declaration in a *condition* (either introduced by the *decl-specifier-seq* or the *declarator* of the condition) is in scope from its point of declaration until the end of the substatements controlled by the condition. If the name is redeclared in the outermost block of a substatement controlled by the condition, the declaration that redeclares the name is ill-formed. [ *Example:* ]

```
if (int x = f()) {
    int x;           // ill-formed, redeclaration of x
}
else {
    int x;           // ill-formed, redeclaration of x
}
```

— *end example* ]

- <sup>4</sup> The value of a *condition* that is an initialized declaration in a statement other than a **switch** statement is the value of the declared variable contextually converted to **bool** (??). If that conversion is ill-formed, the program is ill-formed. The value of a *condition* that is an initialized declaration in a **switch** statement is the value of the declared variable if it has integral or enumeration type, or of that variable implicitly converted to integral or enumeration type otherwise. The value of a *condition* that is an expression is the value of the expression, contextually converted to **bool** for statements other than **switch**; if that conversion is ill-formed, the program is ill-formed. The value of the condition will be referred to as simply “the condition” where the usage is unambiguous.

- <sup>5</sup> If a *condition* can be syntactically resolved as either an expression or the declaration of a block-scope name, it is interpreted as a declaration.
- <sup>6</sup> In the *decl-specifier-seq* of a *condition*, each *decl-specifier* shall be either a *type-specifier* or `constexpr`.

## 9.1 Labeled statement

[stmt.label]

- <sup>1</sup> A statement can be labeled.

*labeled-statement:*

```
attribute-specifier-seqopt identifier : statement
attribute-specifier-seqopt case constant-expression : statement
attribute-specifier-seqopt default : statement
```

The optional *attribute-specifier-seq* appertains to the label. An *identifier* *label* declares the identifier. The only use of an identifier label is as the target of a `goto`. The scope of a label is the function in which it appears. Labels shall not be redeclared within a function. A label can be used in a `goto` statement before its declaration. Labels have their own name space and do not interfere with other identifiers. [ *Note*: A label may have the same name as another declaration in the same scope or a *template-parameter* from an enclosing scope. Unqualified name lookup (??) ignores labels. — *end note* ]

- <sup>2</sup> Case labels and default labels shall occur only in switch statements.

## 9.2 Expression statement

[stmt.expr]

- <sup>1</sup> Expression statements have the form

*expression-statement:*

```
expressionopt ;
```

The expression is a discarded-value expression (??). All side effects from an expression statement are completed before the next statement is executed. An expression statement with the expression missing is called a *null statement*. [ *Note*: Most statements are expression statements — usually assignments or function calls. A null statement is useful to carry a label just before the } of a compound statement and to supply a null body to an iteration statement such as a `while` statement (??). — *end note* ]

## 9.3 Compound statement or block

[stmt.block]

- <sup>1</sup> So that several statements can be used where one is expected, the compound statement (also, and equivalently, called “block”) is provided.

*compound-statement:*

```
{ statement-seqopt }
```

*statement-seq:*

```
statement
```

```
statement-seq statement
```

A compound statement defines a block scope (??). [ *Note*: A declaration is a *statement* (??). — *end note* ]

## 9.4 Selection statements

[stmt.select]

- <sup>1</sup> Selection statements choose one of several flows of control.

*selection-statement:*

```
if constexpropt ( init-statementopt condition ) statement
if constexpropt ( init-statementopt condition ) statement else statement
switch ( init-statementopt condition ) statement
```

See ?? for the optional *attribute-specifier-seq* in a condition. [Note: An *init-statement* ends with a semicolon. —end note] In ??, the term *substatement* refers to the contained *statement* or *statements* that appear in the syntax notation. The substatement in a *selection-statement* (each substatement, in the **else** form of the **if** statement) implicitly defines a block scope (??). If the substatement in a selection-statement is a single statement and not a *compound-statement*, it is as if it was rewritten to be a compound-statement containing the original substatement. [Example:

```
if (x)
    int i;
```

can be equivalently rewritten as

```
if (x) {
    int i;
}
```

Thus after the **if** statement, **i** is no longer in scope. —end example]

#### 9.4.1 The **if** statement

[stmt.if]

- <sup>1</sup> If the condition (??) yields **true** the first substatement is executed. If the **else** part of the selection statement is present and the condition yields **false**, the second substatement is executed. If the first substatement is reached via a label, the condition is not evaluated and the second substatement is not executed. In the second form of **if** statement (the one including **else**), if the first substatement is also an **if** statement then that inner **if** statement shall contain an **else** part.<sup>92</sup>
- <sup>2</sup> If the **if** statement is of the form **if constexpr**, the value of the condition shall be a contextually converted constant expression of type **bool** (??); this form is called a *constexpr if* statement. If the value of the converted condition is **false**, the first substatement is a *discarded statement*, otherwise the second substatement, if present, is a discarded statement. During the instantiation of an enclosing templated entity (??), if the condition is not value-dependent after its instantiation, the discarded substatement (if any) is not instantiated. [Note: Odr-uses (??) in a discarded statement do not require an entity to be defined. —end note] A **case** or **default** label appearing within such an **if** statement shall be associated with a **switch** statement (??) within the same **if** statement. A label (??) declared in a substatement of a **constexpr if** statement shall only be referred to by a statement (??) in the same substatement. [Example:

```
template<typename T, typename ... Rest> void g(T&& p, Rest&& ...rs) {
    // ... handle p

    if constexpr (sizeof...(rs) > 0)
        g(rs...);           // never instantiated with an empty argument list
}

extern int x;           // no definition of x required

int f() {
    if constexpr (true)
        return 0;
    else if (x)
        return x;
```

---

<sup>92</sup>) In other words, the **else** is associated with the nearest un-elsed **if**.

```

    else
        return -x;
}

— end example]

```

- 3 An **if** statement of the form

```
if constexpropt ( init-statement condition ) statement
```

is equivalent to

```
{
    init-statement
    if constexpropt ( condition ) statement
}
```

and an **if** statement of the form

```
if constexpropt ( init-statement condition ) statement else statement
```

is equivalent to

```
{
    init-statement
    if constexpropt ( condition ) statement else statement
}
```

except that names declared in the *init-statement* are in the same declarative region as those declared in the *condition*.

#### 9.4.2 The **switch** statement

[stmt.switch]

- <sup>1</sup> The **switch** statement causes control to be transferred to one of several statements depending on the value of a condition.
- <sup>2</sup> The condition shall be of integral type, enumeration type, or class type. If of class type, the condition is contextually implicitly converted (??) to an integral or enumeration type. If the (possibly converted) type is subject to integral promotions (??), the condition is converted to the promoted type. Any statement within the **switch** statement can be labeled with one or more case labels as follows:

```
case constant-expression :
```

where the *constant-expression* shall be a converted constant expression (??) of the adjusted type of the switch condition. No two of the case constants in the same switch shall have the same value after conversion.

- 3 There shall be at most one label of the form

```
default :
```

within a **switch** statement.

- <sup>4</sup> Switch statements can be nested; a **case** or **default** label is associated with the smallest switch enclosing it.
  - <sup>5</sup> When the **switch** statement is executed, its condition is evaluated and compared with each case constant. If one of the case constants is equal to the value of the condition, control is passed to the statement following the matched case label. If no case constant matches the condition, and if there is a **default** label, control passes to the statement labeled by the default label. If no case matches and if there is no **default** then none of the statements in the switch is executed.
  - <sup>6</sup> **case** and **default** labels in themselves do not alter the flow of control, which continues unimpeded across such labels. To exit from a switch, see **break**, ??.
- [Note: Usually, the substatement that is the subject of a

`switch` is compound and `case` and `default` labels appear on the top-level statements contained within the (compound) substatement, but this is not required. Declarations can appear in the substatement of a `switch` statement. — end note]

- 7 A `switch` statement of the form

```
switch ( init-statement condition ) statement
```

is equivalent to

```
{
    init-statement
    switch ( condition ) statement
}
```

except that names declared in the *init-statement* are in the same declarative region as those declared in the *condition*.

## 9.5 Iteration statements

[stmt.iter]

- 1 Iteration statements specify looping.

```
iteration-statement:
    while ( condition ) statement
    do statement while ( expression ) ;
    for ( init-statement conditionopt ; expressionopt ) statement
    for ( init-statementopt for-range-declaration : for-range-initializer ) statement

for-range-declaration:
    attribute-specifier-seqopt decl-specifier-seq declarator
    attribute-specifier-seqopt decl-specifier-seq ref-qualifieropt [ identifier-list ]

for-range-initializer:
    expr-or-braced-init-list
```

See ?? for the optional *attribute-specifier-seq* in a *for-range-declaration*. [Note: An *init-statement* ends with a semicolon. — end note]

- 2 The substatement in an *iteration-statement* implicitly defines a block scope (??) which is entered and exited each time through the loop.

If the substatement in an iteration-statement is a single statement and not a *compound-statement*, it is as if it was rewritten to be a compound-statement containing the original statement. [Example:

```
while (--x >= 0)
    int i;
```

can be equivalently rewritten as

```
while (--x >= 0) {
    int i;
}
```

Thus after the `while` statement, `i` is no longer in scope. — end example]

- 3 If a name introduced in an *init-statement* or *for-range-declaration* is redeclared in the outermost block of the substatement, the program is ill-formed. [Example:

```
void f() {
    for (int i = 0; i < 10; ++i)
        int i = 0;           // error: redeclaration
```

```

for (int i : { 1, 2, 3 })
    int i = 1;           // error: redeclaration
}
— end example]

```

### 9.5.1 The `while` statement

[stmt.while]

- <sup>1</sup> In the `while` statement the substatement is executed repeatedly until the value of the condition (??) becomes `false`. The test takes place before each execution of the substatement.
- <sup>2</sup> When the condition of a `while` statement is a declaration, the scope of the variable that is declared extends from its point of declaration (??) to the end of the `while statement`. A `while` statement of the form

```
while (T t = x) statement
```

is equivalent to

```

label:
{
    T t = x;           // start of condition scope
    if (t) {
        statement
        goto label;
    }
}                         // end of condition scope

```

The variable created in a condition is destroyed and created with each iteration of the loop. [ *Example*:

```

struct A {
    int val;
    A(int i) : val(i) { }
    ~A() { }
    operator bool() { return val != 0; }
};

int i = 1;
while (A a = i) {
    // ...
    i = 0;
}

```

In the while-loop, the constructor and destructor are each called twice, once for the condition that succeeds and once for the condition that fails. — *end example*]

### 9.5.2 The `do` statement

[stmt.do]

- <sup>1</sup> The expression is contextually converted to `bool` (??); if that conversion is ill-formed, the program is ill-formed.
- <sup>2</sup> In the `do` statement the substatement is executed repeatedly until the value of the expression becomes `false`. The test takes place after each execution of the statement.

### 9.5.3 The `for` statement

[stmt.for]

- <sup>1</sup> The `for` statement

```
for (init-statement conditionopt ; expressionopt) statement
```

is equivalent to

```
{
    init-statement
    while ( condition ) {
        statement
        expression ;
    }
}
```

except that names declared in the *init-statement* are in the same declarative region as those declared in the *condition*, and except that a **continue** in *statement* (not enclosed in another iteration statement) will execute *expression* before re-evaluating *condition*. [ *Note*: Thus the first statement specifies initialization for the loop; the condition (??) specifies a test, sequenced before each iteration, such that the loop is exited when the condition becomes **false**; the expression often specifies incrementing that is sequenced after each iteration. — *end note* ]

- 2 Either or both of the *condition* and the *expression* can be omitted. A missing *condition* makes the implied **while** clause equivalent to **while(true)**.
- 3 If the *init-statement* is a declaration, the scope of the name(s) declared extends to the end of the **for** statement. [ *Example*:

```
int i = 42;
int a[10];

for (int i = 0; i < 10; i++)
    a[i] = i;

int j = i;           // j = 42
— end example ]
```

#### 9.5.4 The range-based for statement

[stmt.ranged]

- 1 The range-based **for** statement

```
for ( init-statementopt for-range-declaration : for-range-initializer ) statement
```

is equivalent to

```
{
    init-statementopt
    auto &&_range = for-range-initializer ;
    auto _begin = begin-expr ;
    auto _end = end-expr ;
    for ( ; _begin != _end; _begin++ ) {
        for-range-declaration = *_begin;
        statement
    }
}
```

where

- (1.1) — if the *for-range-initializer* is an *expression*, it is regarded as if it were surrounded by parentheses (so that a comma operator cannot be reinterpreted as delimiting two *init-declarators*);
- (1.2) — **\_range**, **\_begin**, and **\_end** are variables defined for exposition only; and

- (1.3) — *begin-expr* and *end-expr* are determined as follows:
- (1.3.1) — if the *for-range-initializer* is an expression of array type *R*, *begin-expr* and *end-expr* are `__range` and `__range + __bound`, respectively, where `__bound` is the array bound. If *R* is an array of unknown bound or an array of incomplete type, the program is ill-formed;
  - (1.3.2) — if the *for-range-initializer* is an expression of class type *C*, the *unqualified-ids* `begin` and `end` are looked up in the scope of *C* as if by class member access lookup (??), and if either (or both) finds at least one declaration, *begin-expr* and *end-expr* are `__range.begin()` and `__range.end()`, respectively;
  - (1.3.3) — otherwise, *begin-expr* and *end-expr* are `begin(__range)` and `end(__range)`, respectively, where `begin` and `end` are looked up in the associated namespaces (??). [Note: Ordinary unqualified lookup (??) is not performed. — end note]

[Example:

```
int array[5] = { 1, 2, 3, 4, 5 };
for (int& x : array)
    x *= 2;
```

— end example]

- 2 In the *decl-specifier-seq* of a *for-range-declaration*, each *decl-specifier* shall be either a *type-specifier* or `constexpr`. The *decl-specifier-seq* shall not define a class or enumeration.

## 9.6 Jump statements

[stmt.jump]

- <sup>1</sup> Jump statements unconditionally transfer control.

*jump-statement*:

```
break ;
continue ;
return expr-or-braced-init-listopt ;
goto identifier ;
```

- 2 On exit from a scope (however accomplished), objects with automatic storage duration (??) that have been constructed in that scope are destroyed in the reverse order of their construction. [Note: For temporaries, see ??.. — end note] Transfer out of a loop, out of a block, or back past an initialized variable with automatic storage duration involves the destruction of objects with automatic storage duration that are in scope at the point transferred from but not at the point transferred to. (See ?? for transfers into blocks). [Note: However, the program can be terminated (by calling `std::exit()` or `std::abort()` (??), for example) without destroying class objects with automatic storage duration. — end note]

### 9.6.1 The break statement

[stmt.break]

- <sup>1</sup> The `break` statement shall occur only in an *iteration-statement* or a `switch` statement and causes termination of the smallest enclosing *iteration-statement* or `switch` statement; control passes to the statement following the terminated statement, if any.

### 9.6.2 The continue statement

[stmt.cont]

- <sup>1</sup> The `continue` statement shall occur only in an *iteration-statement* and causes control to pass to the loop-continuation portion of the smallest enclosing *iteration-statement*, that is, to the end of the loop. More precisely, in each of the statements

```

while (foo) {
{
    // ...
}
contin: ;
}

do {
{
    // ...
}
contin: ;
} while (foo);

for (;;) {
{
    // ...
}
contin: ;
}

```

a `continue` not contained in an enclosed iteration statement is equivalent to `goto contin`.

### 9.6.3 The `return` statement

[stmt.return]

- <sup>1</sup> A function returns to its caller by the `return` statement.
- <sup>2</sup> The *expr-or-braced-init-list* of a return statement is called its operand. A return statement with no operand shall be used only in a function whose return type is *cv void*, a constructor (??), or a destructor (??). A return statement with an operand of type `void` shall be used only in a function whose return type is *cv void*. A return statement with any other operand shall be used only in a function whose return type is not *cv void*; the return statement initializes the glvalue result or prvalue result object of the (explicit or implicit) function call by copy-initialization (??) from the operand. [Note: A return statement can involve an invocation of a constructor to perform a copy or move of the operand if it is not a prvalue or if its type differs from the return type of the function. A copy operation associated with a return statement may be elided or converted to a move operation if an automatic storage duration variable is returned (??). —end note] [Example:

```

std::pair<std::string,int> f(const char* p, int x) {
    return {p,x};
}

```

—end example] Flowing off the end of a constructor, a destructor, or a function with a *cv void* return type is equivalent to a `return` with no operand. Otherwise, flowing off the end of a function other than `main` (??) results in undefined behavior.

- <sup>3</sup> The copy-initialization of the result of the call is sequenced before the destruction of temporaries at the end of the full-expression established by the operand of the return statement, which, in turn, is sequenced before the destruction of local variables (??) of the block enclosing the return statement.

### 9.6.4 The `goto` statement

[stmt.goto]

- <sup>1</sup> The `goto` statement unconditionally transfers control to the statement labeled by the identifier. The identifier shall be a label (??) located in the current function.

## 9.7 Declaration statement

[stmt.dcl]

- <sup>1</sup> A declaration statement introduces one or more new identifiers into a block; it has the form

*declaration-statement:*  
    *block-declaration*

If an identifier introduced by a declaration was previously declared in an outer block, the outer declaration is hidden for the remainder of the block, after which it resumes its force.

- <sup>2</sup> Variables with automatic storage duration (??) are initialized each time their *declaration-statement* is executed. Variables with automatic storage duration declared in the block are destroyed on exit from the block (??).

- <sup>3</sup> It is possible to transfer into a block, but not in a way that bypasses declarations with initialization. A program that jumps<sup>93</sup> from a point where a variable with automatic storage duration is not in scope to a point where it is in scope is ill-formed unless the variable has scalar type, class type with a trivial default constructor and a trivial destructor, a cv-qualified version of one of these types, or an array of one of the preceding types and is declared without an *initializer* (??). [Example:

```
void f() {
    // ...
    goto lx;           // ill-formed: jump into scope of a
    // ...
    ly:
    X a = 1;
    // ...
    lx:
    goto ly;          // OK, jump implies destructor call for a followed by
                      // construction again immediately following label ly
}
— end example]
```

- <sup>4</sup> Dynamic initialization of a block-scope variable with static storage duration (??) or thread storage duration (??) is performed the first time control passes through its declaration; such a variable is considered initialized upon the completion of its initialization. If the initialization exits by throwing an exception, the initialization is not complete, so it will be tried again the next time control enters the declaration. If control enters the declaration concurrently while the variable is being initialized, the concurrent execution shall wait for completion of the initialization.<sup>94</sup> If control re-enters the declaration recursively while the variable is being initialized, the behavior is undefined. [Example:

```
int foo(int i) {
    static int s = foo(2*i);      // recursive call - undefined
    return i+1;
}
— end example]
```

- <sup>5</sup> The destructor for a block-scope object with static or thread storage duration will be executed if and only if it was constructed. [Note: ?? describes the order in which block-scope objects with static and thread storage duration are destroyed. — end note]

## 9.8 Ambiguity resolution

[stmt.ambig]

- <sup>1</sup> There is an ambiguity in the grammar involving *expression-statements* and *declarations*: An *expression-statement* with a function-style explicit type conversion (??) as its leftmost subexpression can be indistinguishable from a *declaration* where the first *declarator* starts with a (. In those cases the *statement* is a *declaration*.
- <sup>2</sup> [Note: If the *statement* cannot syntactically be a *declaration*, there is no ambiguity, so this rule does not apply. The whole *statement* might need to be examined to determine whether this is the case. This resolves the meaning of many examples. [Example: Assuming T is a *simple-type-specifier* (??),

```
T(a)->m = 7;           // expression-statement
```

---

93) The transfer from the condition of a `switch` statement to a `case` label is considered a jump in this respect.

94) The implementation must not introduce any deadlock around execution of the initializer. Deadlocks might still be caused by the program logic; the implementation need only avoid deadlocks due to its own synchronization operations.

```

T(a)++;           // expression-statement
T(a,5)<<c;     // expression-statement

T(*d)(int);      // declaration
T(e)[5];         // declaration
T(f) = { 1, 2 }; // declaration
T(*g)(double(3)); // declaration

```

In the last example above, g, which is a pointer to T, is initialized to double(3). This is of course ill-formed for semantic reasons, but that does not affect the syntactic analysis. —end example]

The remaining cases are *declarations*. [Example:

```

class T {
    // ...
public:
    T();
    T(int);
    T(int, int);
};

T(a);           // declaration
T(*b)();        // declaration
T(c)=7;         // declaration
T(d),e,f=3;    // declaration
extern int h;
T(g)(h,2);     // declaration

```

—end example] —end note]

- <sup>3</sup> The disambiguation is purely syntactic; that is, the meaning of the names occurring in such a statement, beyond whether they are *type-names* or not, is not generally used in or changed by the disambiguation. Class templates are instantiated as necessary to determine if a qualified name is a *type-name*. Disambiguation precedes parsing, and a statement disambiguated as a declaration may be an ill-formed declaration. If, during parsing, a name in a template parameter is bound differently than it would be bound during a trial parse, the program is ill-formed. No diagnostic is required. [Note: This can occur only when the name is declared earlier in the declaration. —end note] [Example:

```

struct T1 {
    T1 operator()(int x) { return T1(x); }
    int operator=(int x) { return x; }
    T1(int) { }
};

struct T2 { T2(int){ } };
int a, (*(*b)(T2))(int), c, d;

void f() {
    // disambiguation requires this to be parsed as a declaration:
    T1(a) = 3,
    T2(4),           // T2 will be declared as a variable of type T1, but this will not
    (*(*b)(T2(c)))(int(d)); // allow the last part of the declaration to parse properly,
                           // since it depends on T2 being a type-name
}

```

— *end example* ]

# 10 Declarations

[dcl.dcl]

- <sup>1</sup> Declarations generally specify how names are to be interpreted. Declarations have the form

```

declaration-seq:
    declaration
    declaration-seq declaration

declaration:
    block-declaration
    nodeclspec-function-declaration
    function-definition
    template-declaration
    deduction-guide
    explicit-instantiation
    explicit-specialization
    linkage-specification
    namespace-definition
    empty-declaration
    attribute-declaration

block-declaration:
    simple-declaration
    asm-definition
    namespace-alias-definition
    using-declaration
    using-directive
    static_assert-declaration
    alias-declaration
    opaque-enum-declaration

nodeclspec-function-declaration:
    attribute-specifier-seqopt declarator ;

alias-declaration:
    using identifier attribute-specifier-seqopt = defining-type-id ;

simple-declaration:
    decl-specifier-seq init-declarator-listopt ;
    attribute-specifier-seq decl-specifier-seq init-declarator-list ;
    attribute-specifier-seqopt decl-specifier-seq ref-qualifieropt [ identifier-list ] initializer ;

static_assert-declaration:
    static_assert ( constant-expression ) ;
    static_assert ( constant-expression , string-literal ) ;

empty-declaration:
    ;

attribute-declaration:
    attribute-specifier-seq ;

```

[*Note*: *asm-definitions* are described in ??, and *linkage-specifications* are described in ??. *Function-definitions* are described in ?? and *template-declarations* and *deduction-guides* are described in ?? . *Namespace-definitions* are described in ??, *using-declarations* are described in ?? and *using-directives* are described in ?? . — *end note*]

- <sup>2</sup> A *simple-declaration* or *nodeclspec-function-declaration* of the form

```
attribute-specifier-seqopt decl-specifier-seqopt init-declarator-listopt ;
```

is divided into three parts. Attributes are described in ?? . *decl-specifiers*, the principal components of a *decl-specifier-seq*, are described in ?? . *declarators*, the components of an *init-declarator-list*, are described in ?? . The *attribute-specifier-seq* appertains to each of the entities declared by the *declarators* of the *init-declarator-list*. [*Note*: In the declaration for an entity, attributes appertaining to that entity may appear at the start of the declaration and after the *declarator-id* for that declaration. — *end note*] [*Example*:

```
[[noreturn]] void f [[noreturn]] () ; // OK
```

— *end example*]

- <sup>3</sup> Except where otherwise specified, the meaning of an *attribute-declaration* is implementation-defined.

- <sup>4</sup> A declaration occurs in a scope (??); the scope rules are summarized in ?? . A declaration that declares a function or defines a class, namespace, template, or function also has one or more scopes nested within it. These nested scopes, in turn, can have declarations nested within them. Unless otherwise stated, utterances in ?? about components in, of, or contained by a declaration or subcomponent thereof refer only to those components of the declaration that are *not* nested within scopes nested within the declaration.

- <sup>5</sup> In a *simple-declaration*, the optional *init-declarator-list* can be omitted only when declaring a class (??) or enumeration (??), that is, when the *decl-specifier-seq* contains either a *class-specifier*, an *elaborated-type-specifier* with a *class-key* (??), or an *enum-specifier*. In these cases and whenever a *class-specifier* or *enum-specifier* is present in the *decl-specifier-seq*, the identifiers in these specifiers are among the names being declared by the declaration (as *class-names*, *enum-names*, or *enumerators*, depending on the syntax). In such cases, the *decl-specifier-seq* shall introduce one or more names into the program, or shall redeclare a name introduced by a previous declaration. [*Example*:

```
enum { }; // ill-formed
typedef class { }; // ill-formed
```

— *end example*]

- <sup>6</sup> In a *static\_assert-declaration*, the *constant-expression* shall be a contextually converted constant expression of type *bool* (??). If the value of the expression when so converted is *true*, the declaration has no effect. Otherwise, the program is ill-formed, and the resulting diagnostic message (??) shall include the text of the *string-literal*, if one is supplied, except that characters not in the basic source character set (??) are not required to appear in the diagnostic message. [*Example*:

```
static_assert(char(-1) < 0, "this library requires plain 'char' to be signed");
```

— *end example*]

- <sup>7</sup> An *empty-declaration* has no effect.

- <sup>8</sup> A *simple-declaration* with an *identifier-list* is called a *structured binding declaration* (??). The *decl-specifier-seq* shall contain only the *type-specifier* *auto* (??) and *cv-qualifiers*. The *initializer* shall be of the form “= *assignment-expression*”, of the form “{ *assignment-expression* }”, or of the form “( *assignment-expression* )”, where the *assignment-expression* is of array or non-union class type.

- <sup>9</sup> Each *init-declarator* in the *init-declarator-list* contains exactly one *declarator-id*, which is the name declared by that *init-declarator* and hence one of the names declared by the declaration. The *defining-type-specifiers* (??) in the *decl-specifier-seq* and the recursive *declarator* structure of the *init-declarator* describe a type (??), which is then associated with the name being declared by the *init-declarator*.
- <sup>10</sup> If the *decl-specifier-seq* contains the **typedef** specifier, the declaration is called a *typedef declaration* and the name of each *init-declarator* is declared to be a *typedef-name*, synonymous with its associated type (??). If the *decl-specifier-seq* contains no **typedef** specifier, the declaration is called a *function declaration* if the type associated with the name is a function type (??) and an *object declaration* otherwise.
- <sup>11</sup> Syntactic components beyond those found in the general form of declaration are added to a function declaration to make a *function-definition*. An object declaration, however, is also a definition unless it contains the **extern** specifier and has no initializer (??). A definition causes the appropriate amount of storage to be reserved and any appropriate initialization (??) to be done.
- <sup>12</sup> A *nodeclspec-function-declaration* shall declare a constructor, destructor, or conversion function.<sup>95</sup> [ *Note:* A *nodeclspec-function-declaration* can only be used in a *template-declaration* (??), *explicit-instantiation* (??), or *explicit-specialization* (??). — *end note* ]

## 10.1 Specifiers

[**dcl.spec**]

- <sup>1</sup> The specifiers that can be used in a declaration are

```

decl-specifier:
  storage-class-specifier
  defining-type-specifier
  function-specifier
  friend
  typedef
  constexpr
  inline

decl-specifier-seq:
  decl-specifier attribute-specifier-seqopt
  decl-specifier decl-specifier-seq

```

The optional *attribute-specifier-seq* in a *decl-specifier-seq* appertains to the type determined by the preceding *decl-specifiers* (??). The *attribute-specifier-seq* affects the type only for the declaration it appears in, not other declarations involving the same type.

- <sup>2</sup> Each *decl-specifier* shall appear at most once in a complete *decl-specifier-seq*, except that **long** may appear twice.
- <sup>3</sup> If a *type-name* is encountered while parsing a *decl-specifier-seq*, it is interpreted as part of the *decl-specifier-seq* if and only if there is no previous *defining-type-specifier* other than a *cv-qualifier* in the *decl-specifier-seq*. The sequence shall be self-consistent as described below. [ *Example*:

```

typedef char* Pc;
static Pc;                                // error: name missing

```

Here, the declaration **static** **Pc** is ill-formed because no name was specified for the static variable of type **Pc**. To get a variable called **Pc**, a *type-specifier* (other than **const** or **volatile**) has to be present to indicate that the *typedef-name* **Pc** is the name being (re)declared, rather than being part of the *decl-specifier* sequence. For another example,

---

<sup>95</sup> The “implicit int” rule of C is no longer supported.

```

void f(const Pc);           // void f(char* const) (not const char*)
void g(const int Pc);       // void g(const int)

— end example ]

```

- <sup>4</sup> [ *Note*: Since `signed`, `unsigned`, `long`, and `short` by default imply `int`, a *type-name* appearing after one of those specifiers is treated as the name being (re)declared. [ *Example*:

```

void h(unsigned Pc);        // void h(unsigned int)
void k(unsigned int Pc);    // void k(unsigned int)

— end example ] — end note ]

```

### 10.1.1 Storage class specifiers

[dcl.stc]

- <sup>1</sup> The storage class specifiers are

*storage-class-specifier*:

```

static
thread_local
extern
mutable

```

At most one *storage-class-specifier* shall appear in a given *decl-specifier-seq*, except that `thread_local` may appear with `static` or `extern`. If `thread_local` appears in any declaration of a variable it shall be present in all declarations of that entity. If a *storage-class-specifier* appears in a *decl-specifier-seq*, there can be no `typedef` specifier in the same *decl-specifier-seq* and the *init-declarator-list* or *member-declarator-list* of the declaration shall not be empty (except for an anonymous union declared in a named namespace or in the global namespace, which shall be declared `static` (?)). The *storage-class-specifier* applies to the name declared by each *init-declarator* in the list and not to any names declared by other specifiers. A *storage-class-specifier* other than `thread_local` shall not be specified in an explicit specialization (?) or an explicit instantiation (?) directive.

- <sup>2</sup> [ *Note*: A variable declared without a *storage-class-specifier* at block scope or declared as a function parameter has automatic storage duration by default (?). — end note ]
- <sup>3</sup> The `thread_local` specifier indicates that the named entity has thread storage duration (?). It shall be applied only to the names of variables of namespace or block scope and to the names of static data members. When `thread_local` is applied to a variable of block scope the *storage-class-specifier* `static` is implied if no other *storage-class-specifier* appears in the *decl-specifier-seq*.
- <sup>4</sup> The `static` specifier can be applied only to names of variables and functions and to anonymous unions (?). There can be no `static` function declarations within a block, nor any `static` function parameters. A `static` specifier used in the declaration of a variable declares the variable to have static storage duration (?), unless accompanied by the `thread_local` specifier, which declares the variable to have thread storage duration (?). A `static` specifier can be used in declarations of class members; ?? describes its effect. For the linkage of a name declared with a `static` specifier, see ??.
- <sup>5</sup> The `extern` specifier can be applied only to the names of variables and functions. The `extern` specifier cannot be used in the declaration of class members or function parameters. For the linkage of a name declared with an `extern` specifier, see ?. [ *Note*: The `extern` keyword can also be used in *explicit-instantiations* and *linkage-specifications*, but it is not a *storage-class-specifier* in such contexts. — end note ]
- <sup>6</sup> The linkages implied by successive declarations for a given entity shall agree. That is, within a given scope, each declaration declaring the same variable name or the same overloading of a function name shall imply

the same linkage. Each function in a given set of overloaded functions can have a different linkage, however.

[ *Example:*

```

static char* f();           // f() has internal linkage
char* f()                  // f() still has internal linkage
{ /* ... */ }

char* g();                 // g() has external linkage
static char* g()            // error: inconsistent linkage
{ /* ... */ }

void h();
inline void h();            // external linkage

inline void l();
void l();                  // external linkage

inline void m();
extern void m();            // external linkage

static void n();
inline void n();            // internal linkage

static int a;               // a has internal linkage
int a;                      // error: two definitions

static int b;               // b has internal linkage
extern int b;                // b still has internal linkage

int c;                      // c has external linkage
static int c;                // error: inconsistent linkage

extern int d;               // d has external linkage
static int d;                // error: inconsistent linkage

```

— end example ]

<sup>7</sup> The name of a declared but undefined class can be used in an `extern` declaration. Such a declaration can only be used in ways that do not require a complete class type. [ *Example:*

```

struct S;
extern S a;
extern S f();
extern void g(S);

void h() {
    g(a);                    // error: S is incomplete
    f();                      // error: S is incomplete
}

— end example ]

```

- <sup>8</sup> The **mutable** specifier shall appear only in the declaration of a non-static data member (??) whose type is neither const-qualified nor a reference type. [ *Example*:

```
class X {
    mutable const int* p;           // OK
    mutable int* const q;          // ill-formed
};

— end example ]
```

- <sup>9</sup> The **mutable** specifier on a class data member nullifies a **const** specifier applied to the containing class object and permits modification of the mutable class member even though the rest of the object is **const** (??).

### 10.1.2 Function specifiers

[dcl.fct.spec]

- <sup>1</sup> *Function-specifiers* can be used only in function declarations.

*Function-specifiers* 只能被用在函数声明中。

*function-specifier*:

```
virtual
explicit
```

- <sup>2</sup> The **virtual** specifier shall be used only in the initial declaration of a non-static class member function; see ??.
- <sup>3</sup> The **explicit** specifier shall be used only in the declaration of a constructor or conversion function within its class definition; see ?? and ??.

### 10.1.3 The **typedef** specifier

[dcl.typedef]

- <sup>1</sup> Declarations containing the *decl-specifier* **typedef** declare identifiers that can be used later for naming fundamental (??) or compound (??) types. The **typedef** specifier shall not be combined in a *decl-specifier-seq* with any other kind of specifier except a *defining-type-specifier*, and it shall not be used in the *decl-specifier-seq* of a *parameter-declaration* (??) nor in the *decl-specifier-seq* of a *function-definition* (??). If a **typedef** specifier appears in a declaration without a *declarator*, the program is ill-formed.

*typedef-name*:

```
identifier
```

A name declared with the **typedef** specifier becomes a *typedef-name*. Within the scope of its declaration, a *typedef-name* is syntactically equivalent to a keyword and names the type associated with the identifier in the way described in ???. A *typedef-name* is thus a synonym for another type. A *typedef-name* does not introduce a new type the way a class declaration (??) or enum declaration does. [ *Example*: After

```
typedef int MILES, *KLICKSP;
```

the constructions

```
MILES distance;
extern KLICKSP metricp;
```

are all correct declarations; the type of *distance* is **int** and that of *metricp* is “pointer to **int**”. — end example ]

- <sup>2</sup> A *typedef-name* can also be introduced by an *alias-declaration*. The *identifier* following the **using** keyword becomes a *typedef-name* and the optional *attribute-specifier-seq* following the *identifier* appertains to that *typedef-name*. Such a *typedef-name* has the same semantics as if it were introduced by the **typedef** specifier. In particular, it does not define a new type. [ *Example*:

```

using handler_t = void (*)(int);
extern handler_t ignore;
extern void (*ignore)(int);           // redeclare ignore
using cell = pair<void*, cell*>;    // ill-formed

```

— end example] The *defining-type-specifier-seq* of the *defining-type-id* shall not define a class or enumeration if the *alias-declaration* is the *declaration* of a *template-declaration*.

- 3 In a given non-class scope, a **typedef** specifier can be used to redefine the name of any type declared in that scope to refer to the type to which it already refers. [Example:

```

typedef struct s { /* ... */ } s;
typedef int I;
typedef int I;
typedef I I;

```

— end example]

- 4 In a given class scope, a **typedef** specifier can be used to redefine any *class-name* declared in that scope that is not also a *typedef-name* to refer to the type to which it already refers. [Example:

```

struct S {
    typedef struct A { } A;          // OK
    typedef struct B B;              // OK
    typedef A A;                    // error
};

```

— end example]

- 5 If a **typedef** specifier is used to redefine in a given scope an entity that can be referenced using an *elaborated-type-specifier*, the entity can continue to be referenced by an *elaborated-type-specifier* or as an enumeration or class name in an enumeration or class definition respectively. [Example:

```

struct S;
typedef struct S S;
int main() {
    struct S* p;                  // OK
}
struct S { };                   // OK

```

— end example]

- 6 In a given scope, a **typedef** specifier shall not be used to redefine the name of any type declared in that scope to refer to a different type. [Example:

```

class complex { /* ... */ };
typedef int complex;             // error: redefinition

```

— end example]

- 7 Similarly, in a given scope, a class or enumeration shall not be declared with the same name as a *typedef-name* that is declared in that scope and refers to a type other than the class or enumeration itself. [Example:

```

typedef int complex;
class complex { /* ... */ };     // error: redefinition

```

— end example]

- 8 [Note: A *typedef-name* that names a class type, or a cv-qualified version thereof, is also a *class-name* (??). If a *typedef-name* is used to identify the subject of an *elaborated-type-specifier* (??), a class definition (??),

a constructor declaration (??), or a destructor declaration (??), the program is ill-formed. —end note]  
 [Example:

```
struct S {
    S();
    ~S();
};

typedef struct S T;

S a = T();           // OK
struct T * p;        // error
```

—end example]

- <sup>9</sup> If the `typedef` declaration defines an unnamed class (or enum), the first *typedef-name* declared by the declaration to be that class type (or enum type) is used to denote the class type (or enum type) for linkage purposes only (??). [Note: A `typedef` declaration involving a *lambda-expression* does not itself define the associated closure type, and so the closure type is not given a name for linkage purposes. —end note]

[Example:

```
typedef struct { } *ps, S;           // S is the class name for linkage purposes
typedef decltype([]{}) C;            // the closure type has no name for linkage purposes
—end example]
```

#### 10.1.4 The `friend` specifier

[dcl.friend]

- <sup>1</sup> The `friend` specifier is used to specify access to class members; see ??.

#### 10.1.5 The `constexpr` specifier

[dcl.constexpr]

- <sup>1</sup> The `constexpr` specifier shall be applied only to the definition of a variable or variable template or the declaration of a function or function template. A function or static data member declared with the `constexpr` specifier is implicitly an inline function or variable (??). If any declaration of a function or function template has a `constexpr` specifier, then all its declarations shall contain the `constexpr` specifier. [Note: An explicit specialization can differ from the template declaration with respect to the `constexpr` specifier. —end note]  
 [Note: Function parameters cannot be declared `constexpr`. —end note] [Example:

```
constexpr void square(int &x); // OK: declaration
constexpr int bufsz = 1024;    // OK: definition
constexpr struct pixel {      // error: pixel is a type
    int x;
    int y;
    constexpr pixel(int);     // OK: declaration
};
constexpr pixel::pixel(int a)
: x(a), y(x)                // OK: definition
{ square(x); }
constexpr pixel small(2);     // error: square not defined, so small(2)
                            // not constant (??) so constexpr not satisfied
```

```

constexpr void square(int &x) { // OK: definition
    x *= x;
}
constexpr pixel large(4);           // OK: square defined
int next(constexpr int x) {         // error: not for parameters
    return x + 1;
}
extern constexpr int memsz;          // error: not a definition
— end example]

```

- 2 A `constexpr` specifier used in the declaration of a function that is not a constructor declares that function to be a *constexpr function*. Similarly, a `constexpr` specifier used in a constructor declaration declares that constructor to be a *constexpr constructor*.
- 3 The definition of a `constexpr` function shall satisfy the following requirements:
  - (3.1) — it shall not be virtual (??);
  - (3.2) — its return type shall be a literal type;
  - (3.3) — each of its parameter types shall be a literal type;
  - (3.4) — its *function-body* shall be `= delete`, `= default`, or a *compound-statement* that does not contain
    - (3.4.1) — an *asm-definition*,
    - (3.4.2) — a `goto` statement,
    - (3.4.3) — an identifier label (??),
    - (3.4.4) — a *try-block*, or
    - (3.4.5) — a definition of a variable of non-literal type or of static or thread storage duration or for which no initialization is performed.

[Example:

```

constexpr int square(int x)
    { return x * x; }           // OK
constexpr long long_max()
    { return 2147483647; }       // OK
constexpr int abs(int x) {
    if (x < 0)
        x = -x;
    return x;                  // OK
}
constexpr int first(int n) {
    static int value = n;        // error: variable has static storage duration
    return value;
}
constexpr int uninit() {
    int a;                      // error: variable is uninitialized
    return a;
}
constexpr int prev(int x)
    { return --x; }             // OK

```

```
constexpr int g(int x, int n) { // OK
    int r = 1;
    while (--n > 0) r *= x;
    return r;
}

— end example]
```

- <sup>4</sup> The definition of a `constexpr` constructor shall satisfy the following requirements:

- (4.1) — the class shall not have any virtual base classes;
- (4.2) — each of the parameter types shall be a literal type;
- (4.3) — its *function-body* shall not be a *function-try-block*.

In addition, either its *function-body* shall be `= delete`, or it shall satisfy the following requirements:

- (4.4) — either its *function-body* shall be `= default`, or the *compound-statement* of its *function-body* shall satisfy the requirements for a *function-body* of a `constexpr` function;
- (4.5) — every non-variant non-static data member and base class subobject shall be initialized (??);
- (4.6) — if the class is a union having variant members (??), exactly one of them shall be initialized;
- (4.7) — if the class is a union-like class, but is not a union, for each of its anonymous union members having variant members, exactly one of them shall be initialized;
- (4.8) — for a non-delegating constructor, every constructor selected to initialize non-static data members and base class subobjects shall be a `constexpr` constructor;
- (4.9) — for a delegating constructor, the target constructor shall be a `constexpr` constructor.

[*Example*:

```
struct Length {
    constexpr explicit Length(int i = 0) : val(i) { }
private:
    int val;
};
```

— end example]

- <sup>5</sup> For a `constexpr` function or `constexpr` constructor that is neither defaulted nor a template, if no argument values exist such that an invocation of the function or constructor could be an evaluated subexpression of a core constant expression (??), or, for a constructor, a constant initializer for some object (??), the program is ill-formed, no diagnostic required. [*Example*:

```
constexpr int f(bool b)
    { return b ? throw 0 : 0; }           // OK
constexpr int f() { return f(true); }   // ill-formed, no diagnostic required
```

```
struct B {
    constexpr B(int x) : i(0) { }           // x is unused
    int i;
};

int global;
```

```

struct D : B {
    constexpr D() : B(global) {}           // ill-formed, no diagnostic required
                                                // lvalue-to-rvalue conversion on non-constant global
};

— end example ]

```

- <sup>6</sup> If the instantiated template specialization of a `constexpr` function template or member function of a class template would fail to satisfy the requirements for a `constexpr` function or `constexpr` constructor, that specialization is still a `constexpr` function or `constexpr` constructor, even though a call to such a function cannot appear in a constant expression. If no specialization of the template would satisfy the requirements for a `constexpr` function or `constexpr` constructor when considered as a non-template function or constructor, the template is ill-formed, no diagnostic required.
- <sup>7</sup> A call to a `constexpr` function produces the same result as a call to an equivalent non-`constexpr` function in all respects except that
  - (7.1) — a call to a `constexpr` function can appear in a constant expression (??) and
  - (7.2) — copy elision is mandatory in a constant expression (??).
- <sup>8</sup> The `constexpr` specifier has no effect on the type of a `constexpr` function or a `constexpr` constructor.

[ Example:

```

constexpr int bar(int x, int y)          // OK
    { return x + y + x*y; }
// ...
int bar(int x, int y)                  // error: redefinition of bar
    { return x * 2 + 3 * y; }

```

— end example ]

- <sup>9</sup> A `constexpr` specifier used in an object declaration declares the object as `const`. Such an object shall have literal type and shall be initialized. In any `constexpr` variable declaration, the full-expression of the initialization shall be a constant expression (??). [ Example:

```

struct pixel {
    int x, y;
};
constexpr pixel ur = { 1294, 1024 };    // OK
constexpr pixel origin;                 // error: initializer missing

```

— end example ]

### 10.1.6 The `inline` specifier

[dcl.inline]

- <sup>1</sup> The `inline` specifier can be applied only to the declaration or definition of a variable or function.
- <sup>2</sup> A function declaration (??, ??, ??) with an `inline` specifier declares an *inline function*. The `inline` specifier indicates to the implementation that inline substitution of the function body at the point of call is to be preferred to the usual function call mechanism. An implementation is not required to perform this inline substitution at the point of call; however, even if this inline substitution is omitted, the other rules for inline functions specified in this subclause shall still be respected.
- <sup>3</sup> A variable declaration with an `inline` specifier declares an *inline variable*.
- <sup>4</sup> A function defined within a class definition is an inline function.

- <sup>5</sup> The `inline` specifier shall not appear on a block scope declaration.<sup>96</sup> If the `inline` specifier is used in a friend function declaration, that declaration shall be a definition or the function shall have previously been declared inline.
- <sup>6</sup> An inline function or variable shall be defined in every translation unit in which it is odr-used and shall have exactly the same definition in every case (??). [Note: A call to the inline function or a use of the inline variable may be encountered before its definition appears in the translation unit. —end note] If the definition of a function or variable appears in a translation unit before its first declaration as inline, the program is ill-formed. If a function or variable with external linkage is declared inline in one translation unit, it shall be declared inline in all translation units in which it appears; no diagnostic is required. An inline function or variable with external linkage shall have the same address in all translation units. [Note: A `static` local variable in an inline function with external linkage always refers to the same object. A type defined within the body of an inline function with external linkage is the same type in every translation unit. —end note]

### 10.1.7 Type specifiers

[dcl.type]

- <sup>1</sup> The type-specifiers are

```

type-specifier:
    simple-type-specifier
    elaborated-type-specifier
    typename-specifier
    cv-qualifier

type-specifier-seq:
    type-specifier attribute-specifier-seqopt
    type-specifier type-specifier-seq

defining-type-specifier:
    type-specifier
    class-specifier
    enum-specifier

defining-type-specifier-seq:
    defining-type-specifier attribute-specifier-seqopt
    defining-type-specifier defining-type-specifier-seq

```

The optional *attribute-specifier-seq* in a *type-specifier-seq* or a *defining-type-specifier-seq* appertains to the type denoted by the preceding *type-specifiers* or *defining-type-specifiers* (??). The *attribute-specifier-seq* affects the type only for the declaration it appears in, not other declarations involving the same type.

- <sup>2</sup> As a general rule, at most one *defining-type-specifier* is allowed in the complete *decl-specifier-seq* of a *declaration* or in a *defining-type-specifier-seq*, and at most one *type-specifier* is allowed in a *type-specifier-seq*. The only exceptions to this rule are the following:

- (2.1) — `const` can be combined with any type specifier except itself.
- (2.2) — `volatile` can be combined with any type specifier except itself.
- (2.3) — `signed` or `unsigned` can be combined with `char`, `long`, `short`, or `int`.
- (2.4) — `short` or `long` can be combined with `int`.
- (2.5) — `long` can be combined with `double`.

---

<sup>96</sup>) The `inline` keyword has no effect on the linkage of a function.

- (2.6) — `long` can be combined with `long`.
- 3 Except in a declaration of a constructor, destructor, or conversion function, at least one *defining-type-specifier* that is not a *cv-qualifier* shall appear in a complete *type-specifier-seq* or a complete *decl-specifier-seq*.<sup>97</sup>
- 4 [ *Note*: *enum-specifiers*, *class-specifiers*, and *typename-specifiers* are discussed in ??, ??, and ??, respectively. The remaining *type-specifiers* are discussed in the rest of this subclause. — *end note* ]

### 10.1.7.1 The *cv-qualifiers*

[dcl.type.cv]

- 1 There are two *cv-qualifiers*, `const` and `volatile`. Each *cv-qualifier* shall appear at most once in a *cv-qualifier-seq*. If a *cv-qualifier* appears in a *decl-specifier-seq*, the *init-declarator-list* or *member-declarator-list* of the declaration shall not be empty. [ *Note*: ?? and ?? describe how cv-qualifiers affect object and function types. — *end note* ] Redundant cv-qualifications are ignored. [ *Note*: For example, these could be introduced by `typedefs`. — *end note* ]
- 2 [ *Note*: Declaring a variable `const` can affect its linkage (??) and its usability in constant expressions (??). As described in ??, the definition of an object or subobject of `const`-qualified type must specify an initializer or be subject to default-initialization. — *end note* ]
- 3 A pointer or reference to a *cv-qualified* type need not actually point or refer to a *cv-qualified* object, but it is treated as if it does; a `const`-qualified access path cannot be used to modify an object even if the object referenced is a non-`const` object and can be modified through some other access path. [ *Note*: Cv-qualifiers are supported by the type system so that they cannot be subverted without casting (??). — *end note* ]
- 4 Except that any class member declared `mutable` (??) can be modified, any attempt to modify a `const` object during its lifetime (??) results in undefined behavior. [ *Example*:

```
const int ci = 3;                                // cv-qualified (initialized as required)
ci = 4;                                         // ill-formed: attempt to modify const

int i = 2;                                       // not cv-qualified
const int* cip;                                  // pointer to const int
cip = &i;                                       // OK: cv-qualified access path to unqualified
*cip = 4;                                       // ill-formed: attempt to modify through ptr to const

int* ip;
ip = const_cast<int*>(cip);                    // cast needed to convert const int* to int*
*ip = 4;                                         // defined: *ip points to i, a non-const object

const int* ciq = new const int (3);               // initialized as required
int* iq = const_cast<int*>(ciq);                // cast required
*iq = 4;                                         // undefined: modifies a const object
```

For another example,

```
struct X {
    mutable int i;
    int j;
};

struct Y {
    X x;
```

<sup>97</sup>) There is no special provision for a *decl-specifier-seq* that lacks a *type-specifier* or that has a *type-specifier* that only specifies *cv-qualifiers*. The “implicit int” rule of C is no longer supported.

```

    Y();
}

const Y y;
y.x.i++;                                // well-formed: mutable member can be modified
y.x.j++;                                // ill-formed: const-qualified member modified
Y* p = const_cast<Y*>(&y);             // cast away const-ness of y
p->x.i = 99;                            // well-formed: mutable member can be modified
p->x.j = 99;                            // undefined: modifies a const subobject
— end example]

```

- 5 The semantics of an access through a volatile glvalue are implementation-defined. If an attempt is made to access an object defined with a volatile-qualified type through the use of a non-volatile glvalue, the behavior is undefined.
- 6 [ *Note*: **volatile** is a hint to the implementation to avoid aggressive optimization involving the object because the value of the object might be changed by means undetectable by an implementation. Furthermore, for some implementations, **volatile** might indicate that special hardware instructions are required to access the object. See ?? for detailed semantics. In general, the semantics of **volatile** are intended to be the same in C++ as they are in C. — *end note* ]

### 10.1.7.2 Simple type specifiers

[dcl.type.simple]

- <sup>1</sup> The simple type specifiers are

*simple-type-specifier*:

- nested-name-specifier<sub>opt</sub>* *type-name*
- nested-name-specifier* **template** *simple-template-id*
- nested-name-specifier<sub>opt</sub>* *template-name*
- char*
- char16\_t*
- char32\_t*
- wchar\_t*
- bool*
- short*
- int*
- long*
- signed*
- unsigned*
- float*
- double*
- void*
- auto*
- decltype-specifier*

*type-name*:

- class-name*
- enum-name*
- typedef-name*
- simple-template-id*

*decltype-specifier*:

```
decltype ( expression )
decltype ( auto )
```

- <sup>2</sup> The *simple-type-specifier* `auto` is a placeholder for a type to be deduced (??). A *type-specifier* of the form `typenameopt nested-name-specifieropt template-name` is a placeholder for a deduced class type (??). The *template-name* shall name a class template that is not an injected-class-name. The other *simple-type-specifiers* specify either a previously-declared type, a type determined from an expression, or one of the fundamental types (??). Table ?? summarizes the valid combinations of *simple-type-specifiers* and the types they specify.

Table 11 — *simple-type-specifiers* and the types they specify

Specifier(s)	Type
<i>type-name</i>	the type named
<i>simple-template-id</i>	the type as defined in ??
<i>template-name</i>	placeholder for a type to be deduced
<code>char</code>	<code>"char"</code>
<code>unsigned char</code>	<code>"unsigned char"</code>
<code>signed char</code>	<code>"signed char"</code>
<code>char16_t</code>	<code>"char16_t"</code>
<code>char32_t</code>	<code>"char32_t"</code>
<code>bool</code>	<code>"bool"</code>
<code>unsigned</code>	<code>"unsigned int"</code>
<code>unsigned int</code>	<code>"unsigned int"</code>
<code>signed</code>	<code>"int"</code>
<code>signed int</code>	<code>"int"</code>
<code>int</code>	<code>"int"</code>
<code>unsigned short int</code>	<code>"unsigned short int"</code>
<code>unsigned short</code>	<code>"unsigned short int"</code>
<code>unsigned long int</code>	<code>"unsigned long int"</code>
<code>unsigned long</code>	<code>"unsigned long int"</code>
<code>unsigned long long int</code>	<code>"unsigned long long int"</code>
<code>unsigned long long</code>	<code>"unsigned long long int"</code>
<code>signed long int</code>	<code>"long int"</code>
<code>signed long</code>	<code>"long int"</code>
<code>signed long long int</code>	<code>"long long int"</code>
<code>signed long long</code>	<code>"long long int"</code>
<code>long long int</code>	<code>"long long int"</code>
<code>long long</code>	<code>"long long int"</code>
<code>long int</code>	<code>"long int"</code>
<code>long</code>	<code>"long int"</code>
<code>signed short int</code>	<code>"short int"</code>
<code>signed short</code>	<code>"short int"</code>
<code>short int</code>	<code>"short int"</code>
<code>short</code>	<code>"short int"</code>
<code>wchar_t</code>	<code>"wchar_t"</code>
<code>float</code>	<code>"float"</code>
<code>double</code>	<code>"double"</code>
<code>long double</code>	<code>"long double"</code>
<code>void</code>	<code>"void"</code>
<code>auto</code>	placeholder for a type to be deduced
<code>decltype(auto)</code>	placeholder for a type to be deduced
<code>decltype(expression)</code>	the type as defined below

- <sup>3</sup> When multiple *simple-type-specifiers* are allowed, they can be freely intermixed with other *decl-specifiers* in any order. [ Note: It is implementation-defined whether objects of `char` type are represented as signed or

unsigned quantities. The `signed` specifier forces `char` objects to be signed; it is redundant in other contexts.  
— end note]

- <sup>4</sup> For an expression `e`, the type denoted by `decltype(e)` is defined as follows:

- (4.1) — if `e` is an unparenthesized *id-expression* naming a structured binding (??), `decltype(e)` is the referenced type as given in the specification of the structured binding declaration;
- (4.2) — otherwise, if `e` is an unparenthesized *id-expression* or an unparenthesized class member access (??), `decltype(e)` is the type of the entity named by `e`. If there is no such entity, or if `e` names a set of overloaded functions, the program is ill-formed;
- (4.3) — otherwise, if `e` is an xvalue, `decltype(e)` is `T&&`, where `T` is the type of `e`;
- (4.4) — otherwise, if `e` is an lvalue, `decltype(e)` is `T&`, where `T` is the type of `e`;
- (4.5) — otherwise, `decltype(e)` is the type of `e`.

The operand of the `decltype` specifier is an unevaluated operand (??).

[Example:

```
const int&& foo();
int i;
struct A { double x; };
const A* a = new A();
decltype(foo()) x1 = 17;           // type is const int&&
decltype(i) x2;                  // type is int
decltype(a->x) x3;             // type is double
decltype((a->x)) x4 = x3;      // type is const double&
```

— end example] [Note: The rules for determining types involving `decltype(auto)` are specified in ??.

— end note]

- <sup>5</sup> If the operand of a *decltype-specifier* is a prvalue, the temporary materialization conversion is not applied (??) and no result object is provided for the prvalue. The type of the prvalue may be incomplete. [Note: As a result, storage is not allocated for the prvalue and it is not destroyed. Thus, a class type is not instantiated as a result of being the type of a function call in this context. In this context, the common purpose of writing the expression is merely to refer to its type. In that sense, a *decltype-specifier* is analogous to a use of a *typedef-name*, so the usual reasons for requiring a complete type do not apply. In particular, it is not necessary to allocate storage for a temporary object or to enforce the semantic constraints associated with invoking the type's destructor. — end note] [Note: Unlike the preceding rule, parentheses have no special meaning in this context. — end note] [Example:

```
template<class T> struct A { ~A() = delete; };
template<class T> auto h()
    -> A<T>;
template<class T> auto i(T)      // identity
    -> T;
template<class T> auto f(T)      // #1
    -> decltype(i(h<T>()));
    // forces completion of A<T> and implicitly uses A<T>::~A()
    // for the temporary introduced by the use of h().
    // (A temporary is not introduced as a result of the use of i().)
template<class T> auto f(T)      // #2
    -> void;
```

```

auto g() -> void {
    f(42);                                // OK: calls #2. (#1 is not a viable candidate: type deduction
                                            // fails (??) because A<int>::~A() is implicitly used in its
                                            // decltype-specifier)
}
template<class T> auto q(T)
    -> decltype((h<T>()));           // does not force completion of A<T>; A<T>::~A() is not implicitly
                                            // used within the context of this decltype-specifier
void r() {
    q(42);                                // error: deduction against q succeeds, so overload resolution selects
                                            // the specialization "q(T) -> decltype((h<T>()))" with T=int;
                                            // the return type is A<int>, so a temporary is introduced and its
                                            // destructor is used, so the program is ill-formed
}
— end example]

```

### 10.1.7.3 Elaborated type specifiers

[dcl.type.elab]

*elaborated-type-specifier:*

```

class-key attribute-specifier-seqopt nested-name-specifieropt identifier
class-key simple-template-id
class-key nested-name-specifier templateopt simple-template-id
enum nested-name-specifieropt identifier

```

- <sup>1</sup> An *attribute-specifier-seq* shall not appear in an *elaborated-type-specifier* unless the latter is the sole constituent of a declaration. If an *elaborated-type-specifier* is the sole constituent of a declaration, the declaration is ill-formed unless it is an explicit specialization (??), an explicit instantiation (??) or it has one of the following forms:

```

class-key attribute-specifier-seqopt identifier ;
friend class-key ::opt identifier ;
friend class-key ::opt simple-template-id ;
friend class-key nested-name-specifier identifier ;
friend class-key nested-name-specifier templateopt simple-template-id ;

```

In the first case, the *attribute-specifier-seq*, if any, appertains to the class being declared; the attributes in the *attribute-specifier-seq* are thereafter considered attributes of the class whenever it is named.

- <sup>2</sup> ?? describes how name lookup proceeds for the *identifier* in an *elaborated-type-specifier*. If the *identifier* resolves to a *class-name* or *enum-name*, the *elaborated-type-specifier* introduces it into the declaration the same way a *simple-type-specifier* introduces its *type-name*. If the *identifier* resolves to a *typedef-name* or the *simple-template-id* resolves to an alias template specialization, the *elaborated-type-specifier* is ill-formed. [Note: This implies that, within a class template with a template *type-parameter* T, the declaration

```
friend class T;
```

is ill-formed. However, the similar declaration `friend T;` is allowed (??). — end note]

- <sup>3</sup> The *class-key* or *enum* keyword present in the *elaborated-type-specifier* shall agree in kind with the declaration to which the name in the *elaborated-type-specifier* refers. This rule also applies to the form of *elaborated-type-specifier* that declares a *class-name* or friend class since it can be construed as referring to the definition of the class. Thus, in any *elaborated-type-specifier*, the *enum* keyword shall be used to refer to an enumeration (??), the *union* *class-key* shall be used to refer to a union (??), and either the *class* or *struct* *class-key* shall be used to refer to a class (??) declared using the *class* or *struct* *class-key*. [Example:

```
enum class E { a, b };
enum E x = E::a;           // OK
— end example ]
```

#### 10.1.7.4 The `auto` specifier

[**dcl.spec.auto**]

- <sup>1</sup> The `auto` and `decltype(auto)` *type-specifiers* are used to designate a placeholder type that will be replaced later by deduction from an initializer. The `auto` *type-specifier* is also used to introduce a function type having a *trailing-return-type* or to signify that a lambda is a generic lambda (??). The `auto` *type-specifier* is also used to introduce a structured binding declaration (??).
- <sup>2</sup> The placeholder type can appear with a function declarator in the *decl-specifier-seq*, *type-specifier-seq*, *conversion-function-id*, or *trailing-return-type*, in any context where such a declarator is valid. If the function declarator includes a *trailing-return-type* (??), that *trailing-return-type* specifies the declared return type of the function. Otherwise, the function declarator shall declare a function. If the declared return type of the function contains a placeholder type, the return type of the function is deduced from non-discarded `return` statements, if any, in the body of the function (??).
- <sup>3</sup> The type of a variable declared using `auto` or `decltype(auto)` is deduced from its initializer. This use is allowed in an initializing declaration (??) of a variable. `auto` or `decltype(auto)` shall appear as one of the *decl-specifiers* in the *decl-specifier-seq* and the *decl-specifier-seq* shall be followed by one or more *declarators*, each of which shall be followed by a non-empty *initializer*. In an *initializer* of the form

( *expression-list* )

the *expression-list* shall be a single *assignment-expression*. [ *Example*:

```
auto x = 5;                  // OK: x has type int
const auto *v = &x, u = 6;    // OK: v has type const int*, u has type const int
static auto y = 0.0;          // OK: y has type double
auto int r;                  // error: auto is not a storage-class-specifier
auto f() -> int;            // OK: f returns int
auto g() { return 0.0; }      // OK: g returns double
auto h();                    // OK: h's return type will be deduced when it is defined
```

— end example ]

- <sup>4</sup> A placeholder type can also be used in the *type-specifier-seq* in the *new-type-id* or *type-id* of a *new-expression* (??) and as a *decl-specifier* of the *parameter-declaration*'s *decl-specifier-seq* in a *template-parameter* (??).
- <sup>5</sup> A program that uses `auto` or `decltype(auto)` in a context not explicitly allowed in this subclause is ill-formed.
- <sup>6</sup> If the *init-declarator-list* contains more than one *init-declarator*, they shall all form declarations of variables. The type of each declared variable is determined by placeholder type deduction (??), and if the type that replaces the placeholder type is not the same in each deduction, the program is ill-formed.

[ *Example*:

```
auto x = 5, *y = &x;          // OK: auto is int
auto a = 5, b = { 1, 2 };     // error: different types for auto
```

— end example ]

- <sup>7</sup> If a function with a declared return type that contains a placeholder type has multiple non-discarded `return` statements, the return type is deduced for each such `return` statement. If the type deduced is not the same in each deduction, the program is ill-formed.

- <sup>8</sup> If a function with a declared return type that uses a placeholder type has no non-discarded `return` statements, the return type is deduced as though from a `return` statement with no operand at the closing brace of the function body. [Example:

```
auto f() {} // OK, return type is void
auto* g() {} // error, cannot deduce auto* from void()

— end example]
```

- <sup>9</sup> If the type of an entity with an undeduced placeholder type is needed to determine the type of an expression, the program is ill-formed. Once a non-discarded `return` statement has been seen in a function, however, the return type deduced from that statement can be used in the rest of the function, including in other `return` statements. [Example:

```
auto n = n; // error, n's type is unknown
auto f();
void g() { &f; } // error, f's return type is unknown
auto sum(int i) {
    if (i == 1)
        return i; // sum's return type is int
    else
        return sum(i-1)+i; // OK, sum's return type has been deduced
}

— end example]
```

- <sup>10</sup> Return type deduction for a function template with a placeholder in its declared type occurs when the definition is instantiated even if the function body contains a `return` statement with a non-type-dependent operand. [Note: Therefore, any use of a specialization of the function template will cause an implicit instantiation. Any errors that arise from this instantiation are not in the immediate context of the function type and can result in the program being ill-formed (??). — end note] [Example:

```
template <class T> auto f(T t) { return t; } // return type deduced at instantiation time
typedef decltype(f(1)) fint_t; // instantiates f<int> to deduce return type
template<class T> auto f(T* t) { return *t; }
void g() { int (*p)(int*) = &f; } // instantiates both fs to determine return types,
// chooses second

— end example]
```

- <sup>11</sup> Redeclarations or specializations of a function or function template with a declared return type that uses a placeholder type shall also use that placeholder, not a deduced type. [Example:

```
auto f();
auto f() { return 42; } // return type is int
auto f(); // OK
int f(); // error, cannot be overloaded with auto f()
decltype(auto) f(); // error, auto and decltype(auto) don't match

template <typename T> auto g(T t) { return t; } // #1
template auto g(int); // OK, return type is int
template char g(char); // error, no matching template
template<> auto g(double); // OK, forward declaration with unknown return type

template <class T> T g(T t) { return t; } // OK, not functionally equivalent to #1
```

```

template char g(char);                                // OK, now there is a matching template
template auto g(float);                            // still matches #1

void h() { return g(42); }                         // error, ambiguous

template <typename T> struct A {
    friend T frf(T);
};

auto frf(int i) { return i; }                      // not a friend of A<int>
— end example]

```

- <sup>12</sup> A function declared with a return type that uses a placeholder type shall not be **virtual** (??).
- <sup>13</sup> An explicit instantiation declaration (??) does not cause the instantiation of an entity declared using a placeholder type, but it also does not prevent that entity from being instantiated as needed to determine its type. [Example:

```

template <typename T> auto f(T t) { return t; }
extern template auto f(int);      // does not instantiate f<int>
int (*p)(int) = f;              // instantiates f<int> to determine its return type, but an explicit
                               // instantiation definition is still required somewhere in the program
— end example]

```

#### 10.1.7.4.1 Placeholder type deduction

[dcl.type.auto.deduct]

- <sup>1</sup> *Placeholder type deduction* is the process by which a type containing a placeholder type is replaced by a deduced type.
- <sup>2</sup> A type **T** containing a placeholder type, and a corresponding initializer **e**, are determined as follows:
- (2.1) — for a non-discarded **return** statement that occurs in a function declared with a return type that contains a placeholder type, **T** is the declared return type and **e** is the operand of the **return** statement. If the **return** statement has no operand, then **e** is **void()**;
  - (2.2) — for a variable declared with a type that contains a placeholder type, **T** is the declared type of the variable and **e** is the initializer. If the initialization is direct-list-initialization, the initializer shall be a *braced-init-list* containing only a single *assignment-expression* and **e** is the *assignment-expression*;
  - (2.3) — for a non-type template parameter declared with a type that contains a placeholder type, **T** is the declared type of the non-type template parameter and **e** is the corresponding template argument.

In the case of a **return** statement with no operand or with an operand of type **void**, **T** shall be either **decltype(auto)** or *cv auto*.

- <sup>3</sup> If the deduction is for a **return** statement and **e** is a *braced-init-list* (??), the program is ill-formed.
- <sup>4</sup> If the placeholder is the **auto type-specifier**, the deduced type **T'** replacing **T** is determined using the rules for template argument deduction. Obtain **P** from **T** by replacing the occurrences of **auto** with either a new invented type template parameter **U** or, if the initialization is copy-list-initialization, with **std::initializer\_list<U>**. Deduce a value for **U** using the rules of template argument deduction from a function call (??), where **P** is a function template parameter type and the corresponding argument is **e**. If the deduction fails, the declaration is ill-formed. Otherwise, **T'** is obtained by substituting the deduced **U** into **P**. [Example:

```

auto x1 = { 1, 2 };           // decltype(x1) is std::initializer_list<int>
auto x2 = { 1, 2.0 };        // error: cannot deduce element type

```

```

auto x3{ 1, 2 };           // error: not a single element
auto x4 = { 3 };           // decltype(x4) is std::initializer_list<int>
auto x5{ 3 };              // decltype(x5) is int

— end example]

```

[Example:

```
const auto &i = expr;
```

The type of *i* is the deduced type of the parameter *u* in the call *f(expr)* of the following invented function template:

```

template <class U> void f(const U& u);

— end example]

```

- <sup>5</sup> If the placeholder is the `decltype(auto)` *type-specifier*, *T* shall be the placeholder alone. The type deduced for *T* is determined as described in ??, as though *e* had been the operand of the `decltype`. [Example:

```

int i;
int&& f();
auto      x2a(i);          // decltype(x2a) is int
decltype(auto) x2d(i);     // decltype(x2d) is int
auto      x3a = i;          // decltype(x3a) is int
decltype(auto) x3d = i;     // decltype(x3d) is int
auto      x4a = (i);        // decltype(x4a) is int
decltype(auto) x4d = (i);   // decltype(x4d) is int&
auto      x5a = f();        // decltype(x5a) is int
decltype(auto) x5d = f();   // decltype(x5d) is int&&
auto      x6a = { 1, 2 };    // decltype(x6a) is std::initializer_list<int>
decltype(auto) x6d = { 1, 2 }; // error, { 1, 2 } is not an expression
auto      *x7a = &i;         // decltype(x7a) is int*
decltype(auto)*x7d = &i;    // error, declared type is not plain decltype(auto)

— end example]

```

#### 10.1.7.5 Deduced class template specialization types

[`dcl.type.class.deduct`]

- <sup>1</sup> If a placeholder for a deduced class type appears as a *decl-specifier* in the *decl-specifier-seq* of an initializing declaration (??) of a variable, the placeholder is replaced by the return type of the function selected by overload resolution for class template deduction (??). If the *decl-specifier-seq* is followed by an *init-declarator-list* or *member-declarator-list* containing more than one *declarator*, the type that replaces the placeholder shall be the same in each deduction.
- <sup>2</sup> A placeholder for a deduced class type can also be used in the *type-specifier-seq* in the *new-type-id* or *type-id* of a *new-expression* (??), or as the *simple-type-specifier* in an explicit type conversion (functional notation) (??). A placeholder for a deduced class type shall not appear in any other context.

- <sup>3</sup> [Example:

```

template<class T> struct container {
    container(T t) {}
    template<class Iter> container(Iter beg, Iter end);
};

template<class Iter>
container(Iter b, Iter e) -> container<typename std::iterator_traits<Iter>::value_type>;
std::vector<double> v = { /* ... */ };

```

```

container c(7);                                // OK, deduces int for T
auto d = container(v.begin(), v.end()); // OK, deduces double for T
container e{5, 6};                            // error, int is not an iterator
— end example]

```

## 10.2 Enumeration declarations

[dcl.enum]

- 1 An enumeration is a distinct type (??) with named constants. Its name becomes an *enum-name* within its scope.

```

enum-name:
  identifier

enum-specifier:
  enum-head { enumerator-listopt }
  enum-head { enumerator-list , }

enum-head:
  enum-key attribute-specifier-seqopt enum-head-nameopt enum-baseopt

enum-head-name:
  nested-name-specifieropt identifier

opaque-enum-declaration:
  enum-key attribute-specifier-seqopt nested-name-specifieropt identifier enum-baseopt ;

enum-key:
  enum
  enum class
  enum struct

enum-base:
  : type-specifier-seq

enumerator-list:
  enumerator-definition
  enumerator-list , enumerator-definition

enumerator-definition:
  enumerator
  enumerator = constant-expression

enumerator:
  identifier attribute-specifier-seqopt

```

The optional *attribute-specifier-seq* in the *enum-head* and the *opaque-enum-declaration* appertains to the enumeration; the attributes in that *attribute-specifier-seq* are thereafter considered attributes of the enumeration whenever it is named. A : following “**enum** *nested-name-specifier<sub>opt</sub>* *identifier*” within the *decl-specifier-seq* of a *member-declaration* is parsed as part of an *enum-base*. [Note: This resolves a potential ambiguity between the declaration of an enumeration with an *enum-base* and the declaration of an unnamed bit-field of enumeration type. [Example:

```

struct S {
  enum E : int {};
  enum E : int {} ;           // error: redeclaration of enumeration
};

```

— end example] — end note] If an *opaque-enum-declaration* contains a *nested-name-specifier*, the declaration shall be an explicit specialization (??).

- 2 The enumeration type declared with an *enum-key* of only `enum` is an *unscoped enumeration*, and its *enumerators* are *unscoped enumerators*. The *enum-keys* `enum class` and `enum struct` are semantically equivalent; an enumeration type declared with one of these is a *scoped enumeration*, and its *enumerators* are *scoped enumerators*. The optional *identifier* shall not be omitted in the declaration of a scoped enumeration. The *type-specifier-seq* of an *enum-base* shall name an integral type; any cv-qualification is ignored. An *opaque-enum-declaration* declaring an unscoped enumeration shall not omit the *enum-base*. The identifiers in an *enumerator-list* are declared as constants, and can appear wherever constants are required. An *enumerator-definition* with = gives the associated *enumerator* the value indicated by the *constant-expression*. If the first *enumerator* has no *initializer*, the value of the corresponding constant is zero. An *enumerator-definition* without an *initializer* gives the *enumerator* the value obtained by increasing the value of the previous *enumerator* by one. [Example:

```
enum { a, b, c=0 };
enum { d, e, f=e+2 };
```

defines `a`, `c`, and `d` to be zero, `b` and `e` to be 1, and `f` to be 3. — end example] The optional *attribute-specifier-seq* in an *enumerator* appertains to that enumerator.

- 3 An *opaque-enum-declaration* is either a redeclaration of an enumeration in the current scope or a declaration of a new enumeration. [Note: An enumeration declared by an *opaque-enum-declaration* has fixed underlying type and is a complete type. The list of enumerators can be provided in a later redeclaration with an *enum-specifier*. — end note] A scoped enumeration shall not be later redeclared as unscoped or with a different underlying type. An unscoped enumeration shall not be later redeclared as scoped and each redeclaration shall include an *enum-base* specifying the same underlying type as in the original declaration.
- 4 If the *enum-key* is followed by a *nested-name-specifier*, the *enum-specifier* shall refer to an enumeration that was previously declared directly in the class or namespace to which the *nested-name-specifier* refers (i.e., neither inherited nor introduced by a *using-declaration*), and the *enum-specifier* shall appear in a namespace enclosing the previous declaration.
- 5 Each enumeration defines a type that is different from all other types. Each enumeration also has an *underlying type*. The underlying type can be explicitly specified using an *enum-base*. For a scoped enumeration type, the underlying type is `int` if it is not explicitly specified. In both of these cases, the underlying type is said to be *fixed*. Following the closing brace of an *enum-specifier*, each enumerator has the type of its enumeration. If the underlying type is fixed, the type of each enumerator prior to the closing brace is the underlying type and the *constant-expression* in the *enumerator-definition* shall be a converted constant expression of the underlying type (??). If the underlying type is not fixed, the type of each enumerator prior to the closing brace is determined as follows:
  - (5.1) — If an initializer is specified for an enumerator, the *constant-expression* shall be an integral constant expression (??). If the expression has unscoped enumeration type, the enumerator has the underlying type of that enumeration type, otherwise it has the same type as the expression.
  - (5.2) — If no initializer is specified for the first enumerator, its type is an unspecified signed integral type.
  - (5.3) — Otherwise the type of the enumerator is the same as that of the preceding enumerator unless the incremented value is not representable in that type, in which case the type is an unspecified integral type sufficient to contain the incremented value. If no such type exists, the program is ill-formed.

- <sup>6</sup> An enumeration whose underlying type is fixed is an incomplete type from its point of declaration (??) to immediately after its *enum-base* (if any), at which point it becomes a complete type. An enumeration whose underlying type is not fixed is an incomplete type from its point of declaration to immediately after the closing } of its *enum-specifier*, at which point it becomes a complete type.
- <sup>7</sup> For an enumeration whose underlying type is not fixed, the underlying type is an integral type that can represent all the enumerator values defined in the enumeration. If no integral type can represent all the enumerator values, the enumeration is ill-formed. It is implementation-defined which integral type is used as the underlying type except that the underlying type shall not be larger than `int` unless the value of an enumerator cannot fit in an `int` or `unsigned int`. If the *enumerator-list* is empty, the underlying type is as if the enumeration had a single enumerator with value 0.
- <sup>8</sup> For an enumeration whose underlying type is fixed, the values of the enumeration are the values of the underlying type. Otherwise, for an enumeration where  $e_{\min}$  is the smallest enumerator and  $e_{\max}$  is the largest, the values of the enumeration are the values in the range  $b_{\min}$  to  $b_{\max}$ , defined as follows: Let  $K$  be 1 for a two's complement representation and 0 for a ones' complement or sign-magnitude representation.  $b_{\max}$  is the smallest value greater than or equal to  $\max(|e_{\min}| - K, |e_{\max}|)$  and equal to  $2^M - 1$ , where  $M$  is a non-negative integer.  $b_{\min}$  is zero if  $e_{\min}$  is non-negative and  $-(b_{\max} + K)$  otherwise. The size of the smallest bit-field large enough to hold all the values of the enumeration type is  $\max(M, 1)$  if  $b_{\min}$  is zero and  $M + 1$  otherwise. It is possible to define an enumeration that has values not defined by any of its enumerators. If the *enumerator-list* is empty, the values of the enumeration are as if the enumeration had a single enumerator with value 0.<sup>98</sup>
- <sup>9</sup> Two enumeration types are *layout-compatible enumerations* if they have the same underlying type.
- <sup>10</sup> The value of an enumerator or an object of an unscoped enumeration type is converted to an integer by integral promotion (??). [Example:

```
enum color { red, yellow, green=20, blue };
color col = red;
color* cp = &col;
if (*cp == blue) // ...
```

makes `color` a type describing various colors, and then declares `col` as an object of that type, and `cp` as a pointer to an object of that type. The possible values of an object of type `color` are `red`, `yellow`, `green`, `blue`; these values can be converted to the integral values 0, 1, 20, and 21. Since enumerations are distinct types, objects of type `color` can be assigned only values of type `color`.

```
color c = 1; // error: type mismatch, no conversion from int to color
int i = yellow; // OK: yellow converted to integral value 1, integral promotion
```

Note that this implicit `enum` to `int` conversion is not provided for a scoped enumeration:

```
enum class Col { red, yellow, green };
int x = Col::red; // error: no Col to int conversion
Col y = Col::red;
if (y) {} // error: no Col to bool conversion
— end example]
```

---

<sup>98</sup>) This set of values is used to define promotion and conversion semantics for the enumeration type. It does not preclude an expression of enumeration type from having a value that falls outside this range.

- <sup>11</sup> Each *enum-name* and each unscoped *enumerator* is declared in the scope that immediately contains the *enum-specifier*. Each scoped *enumerator* is declared in the scope of the enumeration. These names obey the scope rules defined for all names in ?? and ??. [Example:

```
enum direction { left='l', right='r' };

void g() {
    direction d;                      // OK
    d = left;                         // OK
    d = direction::right;             // OK
}

enum class altitude { high='h', low='l' };

void h() {
    altitude a;                      // OK
    a = high;                         // error: high not in scope
    a = altitude::low;                // OK
}
```

— end example] An enumerator declared in class scope can be referred to using the class member access operators (::, . (dot) and -> (arrow)), see ??. [Example:

```
struct X {
    enum direction { left='l', right='r' };
    int f(int i) { return i==left ? 0 : i==right ? 1 : 2; }
};

void g(X* p) {
    direction d;                      // error: direction not in scope
    int i;
    i = p->f(left);                 // error: left not in scope
    i = p->f(X::right);             // OK
    i = p->f(p->left);            // OK
    // ...
}
```

— end example]

- <sup>12</sup> If an *enum-head* contains a *nested-name-specifier*, the *enum-specifier* shall refer to an enumeration that was previously declared directly in the class or namespace to which the *nested-name-specifier* refers, or in an element of the inline namespace set (??) of that namespace (i.e., not merely inherited or introduced by a *using-declaration*), and the *enum-specifier* shall appear in a namespace enclosing the previous declaration. In such cases, the *nested-name-specifier* of the *enum-head* of the definition shall not begin with a *decltype-specifier*.

## 10.3 Namespaces

[**basic.namespace**]

- <sup>1</sup> A namespace is an optionally-named declarative region. The name of a namespace can be used to access entities declared in that namespace; that is, the members of the namespace. Unlike other declarative regions, the definition of a namespace can be split over several parts of one or more translation units.
- <sup>2</sup> The outermost declarative region of a translation unit is a namespace; see ??.

### 10.3.1 Namespace definition

[namespace.def]

```

namespace-name:
    identifier
    namespace-alias

namespace-definition:
    named-namespace-definition
    unnamed-namespace-definition
    nested-namespace-definition

named-namespace-definition:
    inlineopt namespace attribute-specifier-seqopt identifier { namespace-body }

unnamed-namespace-definition:
    inlineopt namespace attribute-specifier-seqopt { namespace-body }

nested-namespace-definition:
    namespace enclosing-namespace-specifier :: identifier { namespace-body }

enclosing-namespace-specifier:
    identifier
    enclosing-namespace-specifier :: identifier

namespace-body:
    declaration-seqopt

```

- <sup>1</sup> Every *namespace-definition* shall appear in the global scope or in a namespace scope (??).
- <sup>2</sup> In a *named-namespace-definition*, the *identifier* is the name of the namespace. If the *identifier*, when looked up (??), refers to a *namespace-name* (but not a *namespace-alias*) that was introduced in the namespace in which the *named-namespace-definition* appears or that was introduced in a member of the inline namespace set of that namespace, the *namespace-definition* extends the previously-declared namespace. Otherwise, the *identifier* is introduced as a *namespace-name* into the declarative region in which the *named-namespace-definition* appears.
- <sup>3</sup> Because a *namespace-definition* contains *declarations* in its *namespace-body* and a *namespace-definition* is itself a *declaration*, it follows that *namespace-definitions* can be nested. [ *Example*:

```

namespace Outer {
    int i;
    namespace Inner {
        void f() { i++; }           // Outer::i
        int i;
        void g() { i++; }           // Inner::i
    }
}

```

— end example ]

- <sup>4</sup> The *enclosing namespaces* of a declaration are those namespaces in which the declaration lexically appears, except for a redeclaration of a namespace member outside its original namespace (e.g., a definition as specified in ??). Such a redeclaration has the same enclosing namespaces as the original declaration. [ *Example*:

```

namespace Q {
    namespace V {
        void f();                  // enclosing namespaces are the global namespace, Q, and Q::V
        class C { void m(); };
    }
}

```

```

    }
    void V::f() {                                // enclosing namespaces are the global namespace, Q, and Q::V
        extern void h();                         // ... so this declares Q::V::h
    }
    void V::C::m() {                            // enclosing namespaces are the global namespace, Q, and Q::V
    }
}

— end example ]

```

- <sup>5</sup> If the optional initial `inline` keyword appears in a *namespace-definition* for a particular namespace, that namespace is declared to be an *inline namespace*. The `inline` keyword may be used on a *namespace-definition* that extends a namespace only if it was previously used on the *namespace-definition* that initially declared the *namespace-name* for that namespace.
- <sup>6</sup> The optional *attribute-specifier-seq* in a *named-namespace-definition* appertains to the namespace being defined or extended.
- <sup>7</sup> Members of an inline namespace can be used in most respects as though they were members of the enclosing namespace. Specifically, the inline namespace and its enclosing namespace are both added to the set of associated namespaces used in argument-dependent lookup (??) whenever one of them is, and a *using-directive* (??) that names the inline namespace is implicitly inserted into the enclosing namespace as for an unnamed namespace (??). Furthermore, each member of the inline namespace can subsequently be partially specialized (??), explicitly instantiated (??), or explicitly specialized (??) as though it were a member of the enclosing namespace. Finally, looking up a name in the enclosing namespace via explicit qualification (??) will include members of the inline namespace brought in by the *using-directive* even if there are declarations of that name in the enclosing namespace.
- <sup>8</sup> These properties are transitive: if a namespace *N* contains an inline namespace *M*, which in turn contains an inline namespace *O*, then the members of *O* can be used as though they were members of *M* or *N*. The *inline namespace set* of *N* is the transitive closure of all inline namespaces in *N*. The *enclosing namespace set* of *O* is the set of namespaces consisting of the innermost non-inline namespace enclosing an inline namespace *O*, together with any intervening inline namespaces.
- <sup>9</sup> A *nested-namespace-definition* with an *enclosing-namespace-specifier* *E*, *identifier* *I* and *namespace-body* *B* is equivalent to

```
namespace E { namespace I { B } }
```

[ Example:

```
namespace A::B::C {
    int i;
}
```

The above has the same effect as:

```
namespace A {
    namespace B {
        namespace C {
            int i;
        }
    }
}
```

— end example ]

### 10.3.1.1 Unnamed namespaces

[namespace.unnamed]

- <sup>1</sup> An *unnamed-namespace-definition* behaves as if it were replaced by

```
inlineopt namespace unique { /* empty body */ }
using namespace unique;
namespace unique { namespace-body }
```

where `inline` appears if and only if it appears in the *unnamed-namespace-definition* and all occurrences of `unique` in a translation unit are replaced by the same identifier, and this identifier differs from all other identifiers in the translation unit. The optional *attribute-specifier-seq* in the *unnamed-namespace-definition* appertains to `unique`. [Example:

```
namespace { int i; }           // unique::i
void f() { i++; }             // unique::i++

namespace A {
    namespace {
        int i;                  // A::unique::i
        int j;                  // A::unique::j
    }
    void g() { i++; }          // A::unique::i++
}

using namespace A;
void h() {
    i++;                      // error: unique::i or A::unique::i
    A::i++;                   // A::unique::i
    j++;                      // A::unique::j
}

— end example]
```

### 10.3.1.2 Namespace member definitions

[namespace.memdef]

- <sup>1</sup> A declaration in a namespace *N* (excluding declarations in nested scopes) whose *declarator-id* is an *unqualified-id* (??), whose *class-head-name* (??) or *enum-head-name* (??) is an *identifier*, or whose *elaborated-type-specifier* is of the form *class-key attribute-specifier-seq<sub>opt</sub>* *identifier* (??), or that is an *opaque-enum-declaration*, declares (or redeclares) its *unqualified-id* or *identifier* as a member of *N*. [Note: An explicit instantiation (??) or explicit specialization (??) of a template does not introduce a name and thus may be declared using an *unqualified-id* in a member of the enclosing namespace set, if the primary template is declared in an inline namespace. — end note] [Example:

```
namespace X {
    void f() { /* ... */ }      // OK: introduces X::f()

    namespace M {
        void g();                // OK: introduces X::M::g()
    }
    using M::g;
    void g();                  // error: conflicts with X::M::g()
}

— end example]
```

- <sup>2</sup> Members of a named namespace can also be defined outside that namespace by explicit qualification (??) of the name being defined, provided that the entity being defined was already declared in the namespace and the definition appears after the point of declaration in a namespace that encloses the declaration's namespace. [Example:

```

namespace Q {
    namespace V {
        void f();
    }
    void V::f() { /* ... */ }      // OK
    void V::g() { /* ... */ }      // error: g() is not yet a member of V
    namespace V {
        void g();
    }
}

namespace R {
    void Q::V::g() { /* ... */ }  // error: R doesn't enclose Q
}

```

—end example]

- <sup>3</sup> If a friend declaration in a non-local class first declares a class, function, class template or function template<sup>99</sup> the friend is a member of the innermost enclosing namespace. The friend declaration does not by itself make the name visible to unqualified lookup (??) or qualified lookup (??). [Note: The name of the friend will be visible in its namespace if a matching declaration is provided at namespace scope (either before or after the class definition granting friendship). —end note] If a friend function or function template is called, its name may be found by the name lookup that considers functions from namespaces and classes associated with the types of the function arguments (??). If the name in a friend declaration is neither qualified nor a *template-id* and the declaration is a function or an *elaborated-type-specifier*, the lookup to determine whether the entity has been previously declared shall not consider any scopes outside the innermost enclosing namespace. [Note: The other forms of friend declarations cannot declare a new member of the innermost enclosing namespace and thus follow the usual lookup rules. —end note] [Example:

```

// Assume f and g have not yet been declared.
void h(int);
template <class T> void f2(T);
namespace A {
    class X {
        friend void f(X);           // A::f(X) is a friend
        class Y {
            friend void g();         // A::g is a friend
            friend void h(int);     // A::h is a friend
            // ::h not considered
            friend void f2<>(int); // ::f2<>(int) is a friend
        };
    };
}

// A::f, A::g and A::h are not visible here
X x;

```

<sup>99</sup> this implies that the name of the class or function is unqualified.

```

void g() { f(x); }           // definition of A::g
void f(X) { /* ... */ }      // definition of A::f
void h(int) { /* ... */ }     // definition of A::h
// A::f, A::g and A::h are visible here and known to be friends
}

using A::x;

void h() {
    A::f(x);
    A::X::f(x);             // error: f is not a member of A::X
    A::X::Y::g();            // error: g is not a member of A::X::Y
}
— end example]

```

### 10.3.2 Namespace alias

[namespace.alias]

- 1 A *namespace-alias-definition* declares an alternate name for a namespace according to the following grammar:

```

namespace-alias:
identifier

namespace-alias-definition:
namespace identifier = qualified-namespace-specifier ;

qualified-namespace-specifier:
nested-name-specifieropt namespace-name

```

- 2 The *identifier* in a *namespace-alias-definition* is a synonym for the name of the namespace denoted by the *qualified-namespace-specifier* and becomes a *namespace-alias*. [Note: When looking up a *namespace-name* in a *namespace-alias-definition*, only namespace names are considered, see ?? . — end note]
- 3 In a declarative region, a *namespace-alias-definition* can be used to redefine a *namespace-alias* declared in that declarative region to refer only to the namespace to which it already refers. [Example: The following declarations are well-formed:

```

namespace Company_with_very_long_name { /* ... */ }
namespace CWVLN = Company_with_very_long_name;
namespace CWVLN = Company_with_very_long_name; // OK: duplicate
namespace CWVLN = CWVLN;

— end example]

```

### 10.3.3 The using declaration

[namespace.udcl]

```

using-declaration:
using using-declarator-list ;

using-declarator-list:
using-declarator ...opt
using-declarator-list , using-declarator ...opt

using-declarator:
typenameopt nested-name-specifier unqualified-id

```

- <sup>1</sup> Each *using-declarator* in a *using-declaration*<sup>100</sup> introduces a set of declarations into the declarative region in which the *using-declaration* appears. The set of declarations introduced by the *using-declarator* is found by performing qualified name lookup (??, ??) for the name in the *using-declarator*, excluding functions that are hidden as described below. If the *using-declarator* does not name a constructor, the *unqualified-id* is declared in the declarative region in which the *using-declaration* appears as a synonym for each declaration introduced by the *using-declarator*. [ *Note*: Only the specified name is so declared; specifying an enumeration name in a *using-declaration* does not declare its enumerators in the *using-declaration*'s declarative region. — *end note* ] If the *using-declarator* names a constructor, it declares that the class *inherits* the set of constructor declarations introduced by the *using-declarator* from the nominated base class.
- <sup>2</sup> Every *using-declaration* is a *declaration* and a *member-declaration* and can therefore be used in a class definition. [ *Example*:

```
struct B {
    void f(char);
    void g(char);
    enum E { e };
    union { int x; };
};

struct D : B {
    using B::f;
    void f(int) { f('c'); }           // calls B::f(char)
    void g(int) { g('c'); }           // recursively calls D::g(int)
};

— end example ]
```

- <sup>3</sup> In a *using-declaration* used as a *member-declaration*, each *using-declarator*'s *nested-name-specifier* shall name a base class of the class being defined. If a *using-declarator* names a constructor, its *nested-name-specifier* shall name a direct base class of the class being defined. [ *Example*:

```
template <typename... bases>
struct X : bases... {
    using bases::g...;
};

X<B, D> x;                         // OK: B::g and D::g introduced
```

— *end example* ] [ *Example*:

```
class C {
    int g();
};

class D2 : public B {
    using B::f;                      // OK: B is a base of D2
    using B::e;                      // OK: e is an enumerator of base B
    using B::x;                      // OK: x is a union member of base B
    using C::g;                      // error: C isn't a base of D2
};
```

---

<sup>100</sup> A *using-declaration* with more than one *using-declarator* is equivalent to a corresponding sequence of *using-declarations* with one *using-declarator* each.

— end example ]

- <sup>4</sup> [ Note: Since destructors do not have names, a *using-declaration* cannot refer to a destructor for a base class. Since specializations of member templates for conversion functions are not found by name lookup, they are not considered when a *using-declaration* specifies a conversion function (??). — end note ] If a constructor or assignment operator brought from a base class into a derived class has the signature of a copy/move constructor or assignment operator for the derived class (??), the *using-declaration* does not by itself suppress the implicit declaration of the derived class member; the member from the base class is hidden or overridden by the implicitly-declared copy/move constructor or assignment operator of the derived class, as described below.

- <sup>5</sup> A *using-declaration* shall not name a *template-id*. [ Example:

```
struct A {
    template <class T> void f(T);
    template <class T> struct X { };
};

struct B : A {
    using A::f<double>;           // ill-formed
    using A::X<int>;             // ill-formed
};
```

— end example ]

- <sup>6</sup> A *using-declaration* shall not name a namespace.

- <sup>7</sup> A *using-declaration* shall not name a scoped enumerator.

- <sup>8</sup> A *using-declaration* that names a class member shall be a *member-declaration*. [ Example:

```
struct X {
    int i;
    static int s;
};

void f() {
    using X::i;                  // error: X::i is a class member and this is not a member declaration.
    using X::s;                  // error: X::s is a class member and this is not a member declaration.
}
```

— end example ]

- <sup>9</sup> Members declared by a *using-declaration* can be referred to by explicit qualification just like other member names (??). [ Example:

```
void f();

namespace A {
    void g();
}

namespace X {
    using ::f;                   // global f
    using A::g;                  // A's g
}
```

```

void h()
{
    X::f();           // calls ::f
    X::g();           // calls A::g
}

— end example]

```

- <sup>10</sup> A *using-declaration* is a *declaration* and can therefore be used repeatedly where (and only where) multiple declarations are allowed. [Example:

```

namespace A {
    int i;
}

namespace A1 {
    using A::i, A::i;           // OK: double declaration
}

struct B {
    int i;
};

struct X : B {
    using B::i, B::i;           // error: double member declaration
};

— end example]

```

- <sup>11</sup> [Note: For a *using-declaration* whose *nested-name-specifier* names a namespace, members added to the namespace after the *using-declaration* are not in the set of introduced declarations, so they are not considered when a use of the name is made. Thus, additional overloads added after the *using-declaration* are ignored, but default function arguments (??), default template arguments (??), and template specializations (??, ??) are considered. — end note] [Example:

```

namespace A {
    void f(int);
}

using A::f;           // f is a synonym for A::f; that is, for A::f(int).
namespace A {
    void f(char);
}

void foo() {
    f('a');           // calls f(int), even though f(char) exists.
}

void bar() {
    using A::f;           // f is a synonym for A::f; that is, for A::f(int) and A::f(char).
    f('a');           // calls f(char)
}

— end example]

```

<sup>12</sup> [ *Note*: Partial specializations of class templates are found by looking up the primary class template and then considering all partial specializations of that template. If a *using-declaration* names a class template, partial specializations introduced after the *using-declaration* are effectively visible because the primary template is visible (??). — *end note*]

<sup>13</sup> Since a *using-declaration* is a declaration, the restrictions on declarations of the same name in the same declarative region (??) also apply to *using-declarations*. [ *Example*:

```
namespace A {
    int x;
}

namespace B {
    int i;
    struct g {};
    struct x {};
    void f(int);
    void f(double);
    void g(char);      // OK: hides struct g
}

void func() {
    int i;
    using B::i;        // error: i declared twice
    void f(char);
    using B::f;        // OK: each f is a function
    f(3.5);           // calls B::f(double)
    using B::g;
    g('a');           // calls B::g(char)
    struct g g1;       // g1 has class type B::g
    using B::x;
    using A::x;        // OK: hides struct B::x
    x = 99;            // assigns to A::x
    struct x x1;       // x1 has class type B::x
}
```

— *end example*]

<sup>14</sup> If a function declaration in namespace scope or block scope has the same name and the same parameter-type-list (??) as a function introduced by a *using-declaration*, and the declarations do not declare the same function, the program is ill-formed. If a function template declaration in namespace scope has the same name, parameter-type-list, return type, and template parameter list as a function template introduced by a *using-declaration*, the program is ill-formed. [ *Note*: Two *using-declarations* may introduce functions with the same name and the same parameter-type-list. If, for a call to an unqualified function name, function overload resolution selects the functions introduced by such *using-declarations*, the function call is ill-formed. [ *Example*:

```
namespace B {
    void f(int);
    void f(double);
}
```

```

namespace C {
    void f(int);
    void f(double);
    void f(char);
}

void h() {
    using B::f;           // B::f(int) and B::f(double)
    using C::f;           // C::f(int), C::f(double), and C::f(char)
    f('h');              // calls C::f(char)
    f(1);                // error: ambiguous: B::f(int) or C::f(int)?
    void f(int);          // error: f(int) conflicts with C::f(int) and B::f(int)
}

```

— end example] — end note]

- <sup>15</sup> When a *using-declarator* brings declarations from a base class into a derived class, member functions and member function templates in the derived class override and/or hide member functions and member function templates with the same name, parameter-type-list (??), cv-qualification, and *ref-qualifier* (if any) in a base class (rather than conflicting). Such hidden or overridden declarations are excluded from the set of declarations introduced by the *using-declarator*. [Example:

```

struct B {
    virtual void f(int);
    virtual void f(char);
    void g(int);
    void h(int);
};

struct D : B {
    using B::f;
    void f(int);           // OK: D::f(int) overrides B::f(int);

    using B::g;
    void g(char);          // OK

    using B::h;
    void h(int);           // OK: D::h(int) hides B::h(int)
};

void k(D* p)
{
    p->f(1);              // calls D::f(int)
    p->f('a');             // calls B::f(char)
    p->g(1);               // calls B::g(int)
    p->g('a');              // calls D::g(char)
}

struct B1 {
    B1(int);
};

```

```

struct B2 {
    B2(int);
};

struct D1 : B1, B2 {
    using B1::B1;
    using B2::B2;
};
D1 d1(0);           // ill-formed: ambiguous

struct D2 : B1, B2 {
    using B1::B1;
    using B2::B2;
    D2(int);          // OK: D2::D2(int) hides B1::B1(int) and B2::B2(int)
};
D2 d2(0);           // calls D2::D2(int)

— end example]

```

- <sup>16</sup> For the purpose of forming a set of candidates during overload resolution, the functions that are introduced by a *using-declaration* into a derived class are treated as though they were members of the derived class. In particular, the implicit `this` parameter shall be treated as if it were a pointer to the derived class rather than to the base class. This has no effect on the type of the function, and in all other respects the function remains a member of the base class. Likewise, constructors that are introduced by a *using-declaration* are treated as though they were constructors of the derived class when looking up the constructors of the derived class (??) or forming a set of overload candidates (??, ??, ??). If such a constructor is selected to perform the initialization of an object of class type, all subobjects other than the base class from which the constructor originated are implicitly initialized (??). [Note: A member of a derived class is sometimes preferred to a member of a base class if they would otherwise be ambiguous (??). — end note]
- <sup>17</sup> In a *using-declarator* that does not name a constructor, all members of the set of introduced declarations shall be accessible. In a *using-declarator* that names a constructor, no access check is performed. In particular, if a derived class uses a *using-declarator* to access a member of a base class, the member name shall be accessible. If the name is that of an overloaded member function, then all functions named shall be accessible. The base class members mentioned by a *using-declarator* shall be visible in the scope of at least one of the direct base classes of the class where the *using-declarator* is specified.
- <sup>18</sup> [Note: Because a *using-declarator* designates a base class member (and not a member subobject or a member function of a base class subobject), a *using-declarator* cannot be used to resolve inherited member ambiguities. [Example:

```

struct A { int x(); };
struct B : A {};
struct C : A {
    using A::x;
    int x(int);
};

struct D : B, C {
    using C::x;
}

```

```

    int x(double);
};

int f(D* d) {
    return d->x();      // error: overload resolution selects A::x, but A is an ambiguous base class
}

— end example] — end note]

```

- <sup>19</sup> A synonym created by a *using-declaration* has the usual accessibility for a *member-declaration*. A *using-declarator* that names a constructor does not create a synonym; instead, the additional constructors are accessible if they would be accessible when used to construct an object of the corresponding base class, and the accessibility of the *using-declaration* is ignored. [ *Example*:

```

class A {
private:
    void f(char);
public:
    void f(int);
protected:
    void g();
};

class B : public A {
    using A::f;           // error: A::f(char) is inaccessible
public:
    using A::g;           // B::g is a public synonym for A::g
};

```

— end example]

- <sup>20</sup> If a *using-declarator* uses the keyword `typename` and specifies a dependent name (??), the name introduced by the *using-declaration* is treated as a *typedef-name* (??).

### 10.3.4 Using directive

[**namespace.udir**]

*using-directive*:

```
attribute-specifier-seqopt using namespace nested-name-specifieropt namespace-name ;
```

- <sup>1</sup> A *using-directive* shall not appear in class scope, but may appear in namespace scope or in block scope. [ *Note*: When looking up a *namespace-name* in a *using-directive*, only namespace names are considered, see ???. — end note] The optional *attribute-specifier-seq* appertains to the *using-directive*.
- <sup>2</sup> A *using-directive* specifies that the names in the nominated namespace can be used in the scope in which the *using-directive* appears after the *using-directive*. During unqualified name lookup (??), the names appear as if they were declared in the nearest enclosing namespace which contains both the *using-directive* and the nominated namespace. [ *Note*: In this context, “contains” means “contains directly or indirectly”. — end note]
- <sup>3</sup> A *using-directive* does not add any members to the declarative region in which it appears. [ *Example*:

```

namespace A {
    int i;
    namespace B {
        namespace C {
            int i;

```

```

    }

    using namespace A::B::C;
    void f1() {
        i = 5;           // OK, C::i visible in B and hides A::i
    }
}

namespace D {
    using namespace B;
    using namespace C;
    void f2() {
        i = 5;           // ambiguous, B::C::i or A::i?
    }
}

void f3() {
    i = 5;           // uses A::i
}

void f4() {
    i = 5;           // ill-formed; neither i is visible
}

```

— end example]

- <sup>4</sup> For unqualified lookup (??), the *using-directive* is transitive: if a scope contains a *using-directive* that nominates a second namespace that itself contains *using-directives*, the effect is as if the *using-directives* from the second namespace also appeared in the first. [Note: For qualified lookup, see ??.—end note]  
[Example:

```

namespace M {
    int i;
}

namespace N {
    int i;
    using namespace M;
}

void f() {
    using namespace N;
    i = 7;           // error: both M::i and N::i are visible
}

```

For another example,

```

namespace A {
    int i;
}

namespace B {
    int i;
    int j;
    namespace C {
        namespace D {
            using namespace A;

```

```

    int j;
    int k;
    int a = i;      // B::i hides A::i
}
using namespace D;
int k = 89;      // no problem yet
int l = k;       // ambiguous: C::k or D::k
int m = i;       // B::i hides A::i
int n = j;       // D::j hides B::j
}
}

— end example]
```

- 5 If a namespace is extended (??) after a *using-directive* for that namespace is given, the additional members of the extended namespace and the members of namespaces nominated by *using-directives* in the extending *namespace-definition* can be used after the extending *namespace-definition*.
- 6 If name lookup finds a declaration for a name in two different namespaces, and the declarations do not declare the same entity and do not declare functions, the use of the name is ill-formed. [ *Note*: In particular, the name of a variable, function or enumerator does not hide the name of a class or enumeration declared in a different namespace. For example,

```

namespace A {
    class X {};
    extern "C" int g();
    extern "C++" int h();
}

namespace B {
    void X(int);
    extern "C" int g();
    extern "C++" int h(int);
}

using namespace A;
using namespace B;

void f() {
    X(1);           // error: name X found in two namespaces
    g();            // OK: name g refers to the same entity
    h();            // OK: overload resolution selects A::h
}
```

— end note]

- 7 During overload resolution, all functions from the transitive search are considered for argument matching. The set of declarations found by the transitive search is unordered. [ *Note*: In particular, the order in which namespaces were considered and the relationships among the namespaces implied by the *using-directives* do not cause preference to be given to any of the declarations found by the search. — end note] An ambiguity exists if the best match finds two functions with the same signature, even if one is in a namespace reachable through *using-directives* in the namespace of the other.<sup>101</sup> [ *Example*:

<sup>101</sup> During name lookup in a class hierarchy, some ambiguities may be resolved by considering whether one member hides the other along some paths (??). There is no such disambiguation when considering the set of names found as a result of following *using-directives*.

```

namespace D {
    int d1;
    void f(char);
}
using namespace D;

int d1;           // OK: no conflict with D::d1

namespace E {
    int e;
    void f(int);
}

namespace D {      // namespace extension
    int d2;
    using namespace E;
    void f(int);
}

void f() {
    d1++;          // error: ambiguous ::d1 or D::d1?
    ::d1++;        // OK
    D::d1++;       // OK
    d2++;          // OK: D::d2
    e++;           // OK: E::e
    f(1);          // error: ambiguous: D::f(int) or E::f(int)?
    f('a');        // OK: D::f(char)
}

```

— end example]

## 10.4 The `asm` declaration

[dcl.asm]

- <sup>1</sup> An `asm` declaration has the form

*asm-definition:*  
*attribute-specifier-seq<sub>opt</sub>* `asm` ( *string-literal* ) ;

The `asm` declaration is conditionally-supported; its meaning is implementation-defined. The optional *attribute-specifier-seq* in an *asm-definition* appertains to the `asm` declaration. [ *Note:* Typically it is used to pass information through the implementation to an assembler. — end note ]

## 10.5 Linkage specifications

[dcl.link]

- <sup>1</sup> All function types, function names with external linkage, and variable names with external linkage have a *language linkage*. [ *Note:* Some of the properties associated with an entity with language linkage are specific to each implementation and are not described here. For example, a particular language linkage may be associated with a particular form of representing names of objects and functions with external linkage, or with a particular calling convention, etc. — end note ] The default language linkage of all function types, function names, and variable names is C++ language linkage. Two function types with different language linkages are distinct types even if they are otherwise identical.
- <sup>2</sup> Linkage (??) between C++ and non-C++ code fragments can be achieved using a *linkage-specification*:

*linkage-specification:*

```
extern string-literal { declaration-seqopt }
extern string-literal declaration
```

The *string-literal* indicates the required language linkage. This document specifies the semantics for the *string-literals* "C" and "C++". Use of a *string-literal* other than "C" or "C++" is conditionally-supported, with implementation-defined semantics. [Note: Therefore, a linkage-specification with a *string-literal* that is unknown to the implementation requires a diagnostic. —end note] [Note: It is recommended that the spelling of the *string-literal* be taken from the document defining that language. For example, Ada (not ADA) and Fortran or FORTRAN, depending on the vintage. —end note]

- 3 Every implementation shall provide for linkage to functions written in the C programming language, "C", and linkage to C++ functions, "C++". [Example:

```
complex sqrt(complex);           // C++ linkage by default
extern "C" {
    double sqrt(double);        // C linkage
}
```

—end example]

- 4 Linkage specifications nest. When linkage specifications nest, the innermost one determines the language linkage. A linkage specification does not establish a scope. A *linkage-specification* shall occur only in namespace scope (??). In a *linkage-specification*, the specified language linkage applies to the function types of all function declarators, function names with external linkage, and variable names with external linkage declared within the *linkage-specification*. [Example:

```
extern "C"                                // the name f1 and its function type have C language linkage;
void f1(void(*pf)(int));                  // pf is a pointer to a C function

extern "C" typedef void FUNC();
FUNC f2;                                  // the name f2 has C++ language linkage and the
                                         // function's type has C language linkage

extern "C" FUNC f3;                      // the name of function f3 and the function's type have C language linkage

void (*pf2)(FUNC*);                     // the name of the variable pf2 has C++ linkage and the type
                                         // of pf2 is “pointer to C++ function that takes one parameter of type
                                         // pointer to C function”

extern "C" {
    static void f4();                    // the name of the function f4 has internal linkage (not C language linkage)
                                         // and the function's type has C language linkage.
}

extern "C" void f5() {
    extern void f4();                  // OK: Name linkage (internal) and function type linkage (C language linkage)
                                         // obtained from previous declaration.
}

extern void f4();                        // OK: Name linkage (internal) and function type linkage (C language linkage)
                                         // obtained from previous declaration.
```

```
void f6() {
    extern void f4(); // OK: Name linkage (internal) and function type linkage (C language linkage)
                      // obtained from previous declaration.
}
```

— end example] A C language linkage is ignored in determining the language linkage of the names of class members and the function type of class member functions. [ Example:

```
extern "C" typedef void FUNC_c();

class C {
    void mf1(FUNC_c*); // the name of the function mf1 and the member function's type have
                        // C++ language linkage; the parameter has type “pointer to C function”

    FUNC_c mf2; // the name of the function mf2 and the member function's type have
                 // C++ language linkage

    static FUNC_c* q; // the name of the data member q has C++ language linkage and
                      // the data member's type is “pointer to C function”
};

extern "C" {
    class X {
        void mf(); // the name of the function mf and the member function's type have
                   // C++ language linkage

        void mf2(void(*)()); // the name of the function mf2 has C++ language linkage;
                            // the parameter has type “pointer to C function”
    };
}
```

— end example]

- <sup>5</sup> If two declarations declare functions with the same name and parameter-type-list (??) to be members of the same namespace or declare objects with the same name to be members of the same namespace and the declarations give the names different language linkages, the program is ill-formed; no diagnostic is required if the declarations appear in different translation units. Except for functions with C++ linkage, a function declaration without a linkage specification shall not precede the first linkage specification for that function. A function can be declared without a linkage specification after an explicit linkage specification has been seen; the linkage explicitly specified in the earlier declaration is not affected by such a function declaration.
- <sup>6</sup> At most one function with a particular name can have C language linkage. Two declarations for a function with C language linkage with the same function name (ignoring the namespace names that qualify it) that appear in different namespace scopes refer to the same function. Two declarations for a variable with C language linkage with the same name (ignoring the namespace names that qualify it) that appear in different namespace scopes refer to the same variable. An entity with C language linkage shall not be declared with the same name as a variable in global scope, unless both declarations denote the same entity; no diagnostic is required if the declarations appear in different translation units. A variable with C language linkage shall not be declared with the same name as a function with C language linkage (ignoring the namespace names that qualify the respective names); no diagnostic is required if the declarations appear in different translation units. [ Note: Only one definition for an entity with a given name with C language linkage may appear in

the program (see ??); this implies that such an entity must not be defined in more than one namespace scope. — *end note*] [Example:

```

int x;
namespace A {
    extern "C" int f();
    extern "C" int g() { return 1; }
    extern "C" int h();
    extern "C" int x();           // ill-formed: same name as global-space object x
}

namespace B {
    extern "C" int f();          // A::f and B::f refer to the same function
    extern "C" int g() { return 1; } // ill-formed, the function g with C language linkage has two definitions
}

int A::f() { return 98; }        // definition for the function f with C language linkage
extern "C" int h() { return 97; } // definition for the function h with C language linkage
                                // A::h and ::h refer to the same function

— end example]

```

- 7 A declaration directly contained in a *linkage-specification* is treated as if it contains the `extern` specifier (??) for the purpose of determining the linkage of the declared name and whether it is a definition. Such a declaration shall not specify a storage class. [Example:

```

extern "C" double f();
static double f();             // error
extern "C" int i;              // declaration
extern "C" {
    int i;                     // definition
}
extern "C" static void g();     // error

```

— end example]

- 8 [Note: Because the language linkage is part of a function type, when indirecting through a pointer to C function, the function to which the resulting lvalue refers is considered a C function. — *end note*]  
 9 Linkage from C++ to objects defined in other languages and to objects defined in C++ from other languages is implementation-defined and language-dependent. Only where the object layout strategies of two language implementations are similar enough can such linkage be achieved.

## 10.6 Attributes

[dcl.attr]

### 10.6.1 Attribute syntax and semantics

[dcl.attr.grammar]

- <sup>1</sup> Attributes specify additional information for various source constructs such as types, variables, names, blocks, or translation units.

```

attribute-specifier-seq:
    attribute-specifier-seqopt attribute-specifier

attribute-specifier:
    [ [ attribute-using-prefixopt attribute-list ] ]
    alignment-specifier

```

*alignment-specifier:*

```
alignas ( type-id ...opt )
alignas ( constant-expression ...opt )
```

*attribute-using-prefix:*

```
using attribute-namespace :
```

*attribute-list:*

```
attributeopt
attribute-list , attributeopt
attribute ...
attribute-list , attribute ...
```

*attribute:*

```
attribute-token attribute-argument-clauseopt
```

*attribute-token:*

```
identifier
attribute-scoped-token
```

*attribute-scoped-token:*

```
attribute-namespace :: identifier
```

*attribute-namespace:*

```
identifier
```

*attribute-argument-clause:*

```
( balanced-token-seqopt )
```

*balanced-token-seq:*

```
balanced-token
balanced-token-seq balanced-token
```

*balanced-token:*

```
( balanced-token-seqopt )
[ balanced-token-seqopt ]
{ balanced-token-seqopt }
any token other than a parenthesis, a bracket, or a brace
```

- <sup>2</sup> If an *attribute-specifier* contains an *attribute-using-prefix*, the *attribute-list* following that *attribute-using-prefix* shall not contain an *attribute-scoped-token* and every *attribute-token* in that *attribute-list* is treated as if its *identifier* were prefixed with N:::, where N is the *attribute-namespace* specified in the *attribute-using-prefix*. [Note: This rule imposes no constraints on how an *attribute-using-prefix* affects the tokens in an *attribute-argument-clause*. — end note] [Example:

```
[[using CC: opt(1), debug]]           // same as [[CC::opt(1), CC::debug]]
void f() {}
[[using CC: opt(1)]] [[CC::debug]]    // same as [[CC::opt(1)]] [[CC::debug]]
void g() {}
[[using CC: CC::opt(1)]]             // error: cannot combine using and scoped attribute token
void h() {}
```

— end example]

- <sup>3</sup> [Note: For each individual attribute, the form of the *balanced-token-seq* will be specified. — end note]

- <sup>4</sup> In an *attribute-list*, an ellipsis may appear only if that *attribute*'s specification permits it. An *attribute* followed by an ellipsis is a pack expansion (??). An *attribute-specifier* that contains no *attributes* has no effect.

The order in which the *attribute-tokens* appear in an *attribute-list* is not significant. If a keyword (??) or an alternative token (??) that satisfies the syntactic requirements of an *identifier* (??) is contained in an *attribute-token*, it is considered an identifier. No name lookup (??) is performed on any of the identifiers contained in an *attribute-token*. The *attribute-token* determines additional requirements on the *attribute-argument-clause* (if any).

- 5 Each *attribute-specifier-seq* is said to *appertain* to some entity or statement, identified by the syntactic context where it appears (??, ??, ??). If an *attribute-specifier-seq* that appertains to some entity or statement contains an *attribute* or *alignment-specifier* that is not allowed to apply to that entity or statement, the program is ill-formed. If an *attribute-specifier-seq* appertains to a friend declaration (??), that declaration shall be a definition. No *attribute-specifier-seq* shall appertain to an explicit instantiation (??).
- 6 For an *attribute-token* (including an *attribute-scoped-token*) not specified in this document, the behavior is implementation-defined. Any *attribute-token* that is not recognized by the implementation is ignored. [ *Note*: Each implementation should choose a distinctive name for the *attribute-namespace* in an *attribute-scoped-token*. — *end note* ]
- 7 Two consecutive left square bracket tokens shall appear only when introducing an *attribute-specifier* or within the *balanced-token-seq* of an *attribute-argument-clause*. [ *Note*: If two consecutive left square brackets appear where an *attribute-specifier* is not allowed, the program is ill-formed even if the brackets match an alternative grammar production. — *end note* ] [ *Example*:

```
int p[10];
void f() {
    int x = 42, y[5];
    int(p[[x] { return x; }()]); // error: invalid attribute on a nested declarator-id and
                                // not a function-style cast of an element of p.
    y[] { return 2; }() = 2; // error even though attributes are not allowed in this context.
    int i [[vendor::attr([[[]])]]; // well-formed implementation-defined attribute.
}
```

— *end example* ]

## 10.6.2 Alignment specifier

[**dcl.align**]

- 1 An *alignment-specifier* may be applied to a variable or to a class data member, but it shall not be applied to a bit-field, a function parameter, or an *exception-declaration* (??). An *alignment-specifier* may also be applied to the declaration or definition of a class (in an *elaborated-type-specifier* (??) or *class-head* (??), respectively) and to the declaration or definition of an enumeration (in an *opaque-enum-declaration* or *enum-head*, respectively (??)). An *alignment-specifier* with an ellipsis is a pack expansion (??).
- 2 When the *alignment-specifier* is of the form `alignas( constant-expression )`:
  - (2.1) — the *constant-expression* shall be an integral constant expression
  - (2.2) — if the constant expression does not evaluate to an alignment value (??), or evaluates to an extended alignment and the implementation does not support that alignment in the context of the declaration, the program is ill-formed.
- 3 An *alignment-specifier* of the form `alignas( type-id )` has the same effect as `alignas(alignof( type-id ))` (??).
- 4 The alignment requirement of an entity is the strictest nonzero alignment specified by its *alignment-specifiers*, if any; otherwise, the *alignment-specifiers* have no effect.

- <sup>5</sup> The combined effect of all *alignment-specifiers* in a declaration shall not specify an alignment that is less strict than the alignment that would be required for the entity being declared if all *alignment-specifiers* appertaining to that entity were omitted. [ *Example*:

```
struct alignas(8) S {};
struct alignas(1) U {
    S s;
}; // error: U specifies an alignment that is less strict than if the alignas(1) were omitted.
— end example]
```

- <sup>6</sup> If the defining declaration of an entity has an *alignment-specifier*, any non-defining declaration of that entity shall either specify equivalent alignment or have no *alignment-specifier*. Conversely, if any declaration of an entity has an *alignment-specifier*, every defining declaration of that entity shall specify an equivalent alignment. No diagnostic is required if declarations of an entity have different *alignment-specifiers* in different translation units. [ *Example*:

```
// Translation unit #1:
struct S { int x; } s, *p = &s;

// Translation unit #2:
struct alignas(16) S;           // error: definition of S lacks alignment, no diagnostic required
extern S* p;
— end example]
```

- <sup>7</sup> [ *Example*: An aligned buffer with an alignment requirement of A and holding N elements of type T can be declared as:

```
alignas(T) alignas(A) T buffer[N];
```

Specifying `alignas(T)` ensures that the final requested alignment will not be weaker than `alignof(T)`, and therefore the program will not be ill-formed. — *end example*]

- <sup>8</sup> [ *Example*:

```
alignas(double) void f();                      // error: alignment applied to function
alignas(double) unsigned char c[sizeof(double)]; // array of characters, suitably aligned for a double
extern unsigned char c[sizeof(double)];          // no alignas necessary
alignas(float)
extern unsigned char c[sizeof(double)];          // error: different alignment in declaration
— end example]
```

### 10.6.3 Carries dependency attribute

[**dcl.attr.depend**]

- <sup>1</sup> The *attribute-token* `carries_dependency` specifies dependency propagation into and out of functions. It shall appear at most once in each *attribute-list* and no *attribute-argument-clause* shall be present. The attribute may be applied to the *declarator-id* of a *parameter-declaration* in a function declaration or lambda, in which case it specifies that the initialization of the parameter carries a dependency to (??) each lvalue-to-rvalue conversion (??) of that object. The attribute may also be applied to the *declarator-id* of a function declaration, in which case it specifies that the return value, if any, carries a dependency to the evaluation of the function call expression.
- <sup>2</sup> The first declaration of a function shall specify the `carries_dependency` attribute for its *declarator-id* if any declaration of the function specifies the `carries_dependency` attribute. Furthermore, the first declaration of a function shall specify the `carries_dependency` attribute for a parameter if any declaration of that function

specifies the `carries_dependency` attribute for that parameter. If a function or one of its parameters is declared with the `carries_dependency` attribute in its first declaration in one translation unit and the same function or one of its parameters is declared without the `carries_dependency` attribute in its first declaration in another translation unit, the program is ill-formed, no diagnostic required.

<sup>3</sup> [ *Note:* The `carries_dependency` attribute does not change the meaning of the program, but may result in generation of more efficient code. — *end note* ]

<sup>4</sup> [ *Example:*

```
/* Translation unit A. */

struct foo { int* a; int* b; };
std::atomic<struct foo *> foo_head[10];
int foo_array[10][10];

[[carries_dependency]] struct foo* f(int i) {
    return foo_head[i].load(memory_order::consume);
}

int g(int* x, int* y [[carries_dependency]]) {
    return kill_dependency(foo_array[*x][*y]);
}
```

```
/* Translation unit B. */

[[carries_dependency]] struct foo* f(int i);
int g(int* x, int* y [[carries_dependency]]);

int c = 3;

void h(int i) {
    struct foo* p;

    p = f(i);
    do_something_with(g(&c, p->a));
    do_something_with(g(p->a, &c));
}
```

The `carries_dependency` attribute on function `f` means that the return value carries a dependency out of `f`, so that the implementation need not constrain ordering upon return from `f`. Implementations of `f` and its caller may choose to preserve dependencies instead of emitting hardware memory ordering instructions (a.k.a. fences). Function `g`'s second parameter has a `carries_dependency` attribute, but its first parameter does not. Therefore, function `h`'s first call to `g` carries a dependency into `g`, but its second call does not. The implementation might need to insert a fence prior to the second call to `g`. — *end example* ]

#### 10.6.4 Deprecated attribute

[`dcl.attr.deprecated`]

<sup>1</sup> The *attribute-token* `deprecated` can be used to mark names and entities whose use is still allowed, but is discouraged for some reason. [ *Note:* In particular, `deprecated` is appropriate for names and entities that are deemed obsolescent or unsafe. — *end note* ] It shall appear at most once in each *attribute-list*. An *attribute-argument-clause* may be present and, if present, it shall have the form:

( *string-literal* )

[*Note*: The *string-literal* in the *attribute-argument-clause* could be used to explain the rationale for deprecation and/or to suggest a replacing entity. — *end note*]

- <sup>2</sup> The attribute may be applied to the declaration of a class, a *typedef-name*, a variable, a non-static data member, a function, a namespace, an enumeration, an enumerator, or a template specialization.
- <sup>3</sup> A name or entity declared without the **deprecated** attribute can later be redeclared with the attribute and vice-versa. [*Note*: Thus, an entity initially declared without the attribute can be marked as deprecated by a subsequent redeclaration. However, after an entity is marked as deprecated, later redeclarations do not un-deprecate the entity. — *end note*] Redeclarations using different forms of the attribute (with or without the *attribute-argument-clause* or with different *attribute-argument-clauses*) are allowed.
- <sup>4</sup> [*Note*: Implementations may use the **deprecated** attribute to produce a diagnostic message in case the program refers to a name or entity other than to declare it, after a declaration that specifies the attribute. The diagnostic message may include the text provided within the *attribute-argument-clause* of any **deprecated** attribute applied to the name or entity. — *end note*]

### 10.6.5 Fallthrough attribute

[**dcl.attr.fallthrough**]

- <sup>1</sup> The *attribute-token* **fallthrough** may be applied to a null statement (??); such a statement is a fallthrough statement. The *attribute-token* **fallthrough** shall appear at most once in each *attribute-list* and no *attribute-argument-clause* shall be present. A fallthrough statement may only appear within an enclosing **switch** statement (??). The next statement that would be executed after a fallthrough statement shall be a labeled statement whose label is a case label or default label for the same **switch** statement. The program is ill-formed if there is no such statement.
- <sup>2</sup> [*Note*: The use of a fallthrough statement is intended to suppress a warning that an implementation might otherwise issue for a case or default label that is reachable from another case or default label along some path of execution. Implementations should issue a warning if a fallthrough statement is not dynamically reachable. — *end note*]
- <sup>3</sup> [*Example*:

```
void f(int n) {
    void g(), h(), i();
    switch (n) {
        case 1:
        case 2:
            g();
            [[fallthrough]];
        case 3: // warning on fallthrough discouraged
            h();
        case 4: // implementation may warn on fallthrough
            i();
            [[fallthrough]]; // ill-formed
    }
}
```

— *end example* ]

### 10.6.6 Maybe unused attribute

[**dcl.attr.unused**]

- <sup>1</sup> The *attribute-token* `maybe_unused` indicates that a name or entity is possibly intentionally unused. It shall appear at most once in each *attribute-list* and no *attribute-argument-clause* shall be present.
- <sup>2</sup> The attribute may be applied to the declaration of a class, a *typedef-name*, a variable, a non-static data member, a function, an enumeration, or an enumerator.
- <sup>3</sup> [*Note*: For an entity marked `maybe_unused`, implementations should not emit a warning that the entity is unused, or that the entity is used despite the presence of the attribute. — *end note*]
- <sup>4</sup> A name or entity declared without the `maybe_unused` attribute can later be redeclared with the attribute and vice versa. An entity is considered marked after the first declaration that marks it.
- <sup>5</sup> [*Example*:

```
[[maybe_unused]] void f([[maybe_unused]] bool thing1,
[[maybe_unused]] bool thing2) {
    [[maybe_unused]] bool b = thing1 && thing2;
    assert(b);
}
```

Implementations should not warn that `b` is unused, whether or not `NDEBUG` is defined. — *end example*]

### 10.6.7 Nodiscard attribute

[**dcl.attr.nodiscard**]

- <sup>1</sup> The *attribute-token* `nodiscard` may be applied to the *declarator-id* in a function declaration or to the declaration of a class or enumeration. It shall appear at most once in each *attribute-list* and no *attribute-argument-clause* shall be present.
- <sup>2</sup> [*Note*: A nodiscard call is a function call expression that calls a function previously declared `nodiscard`, or whose return type is a possibly cv-qualified class or enumeration type marked `nodiscard`. Appearance of a nodiscard call as a potentially-evaluated discarded-value expression (??) is discouraged unless explicitly cast to `void`. Implementations should issue a warning in such cases. This is typically because discarding the return value of a nodiscard call has surprising consequences. — *end note*]
- <sup>3</sup> [*Example*:

```
struct [[nodiscard]] error_info { /* ... */ };
error_info enable_missile_safety_mode();
void launch_missiles();
void test_missiles() {
    enable_missile_safety_mode(); // warning encouraged
    launch_missiles();
}
error_info &foo();
void f() { foo(); }           // warning not encouraged: not a nodiscard call, because neither
                             // the (reference) return type nor the function is declared nodiscard
```

— *end example*]

### 10.6.8 Noreturn attribute

[**dcl.attr.noreturn**]

- <sup>1</sup> The *attribute-token* `noreturn` specifies that a function does not return. It shall appear at most once in each *attribute-list* and no *attribute-argument-clause* shall be present. The attribute may be applied to the *declarator-id* in a function declaration. The first declaration of a function shall specify the `noreturn` attribute if any declaration of that function specifies the `noreturn` attribute. If a function is declared with

the `noreturn` attribute in one translation unit and the same function is declared without the `noreturn` attribute in another translation unit, the program is ill-formed, no diagnostic required.

- 2 If a function `f` is called where `f` was previously declared with the `noreturn` attribute and `f` eventually returns, the behavior is undefined. [Note: The function may terminate by throwing an exception. —end note] [Note: Implementations should issue a warning if a function marked `[[noreturn]]` might return. —end note]

- 3 [Example:

```
[[ noreturn ]] void f() {
    throw "error";           // OK
}

[[ noreturn ]] void q(int i) { // behavior is undefined if called with an argument <= 0
    if (i > 0)
        throw "positive";
}
```

—end example]

# 11 Declarators

[dcl.decl]

- <sup>1</sup> A declarator declares a single variable, function, or type, within a declaration. The *init-declarator-list* appearing in a declaration is a comma-separated sequence of declarators, each of which can have an initializer.

```

init-declarator-list:
  init-declarator
  init-declarator-list , init-declarator

init-declarator:
  declarator initializeropt
  declarator requires-clause

```

- <sup>2</sup> The three components of a *simple-declaration* are the attributes (??), the specifiers (*decl-specifier-seq*; ??) and the declarators (*init-declarator-list*). The specifiers indicate the type, storage class or other properties of the entities being declared. The declarators specify the names of these entities and (optionally) modify the type of the specifiers with operators such as \* (pointer to) and () (function returning). Initial values can also be specified in a declarator; initializers are discussed in ?? and ??.
- <sup>3</sup> Each *init-declarator* in a declaration is analyzed separately as if it was in a declaration by itself. [Note: A declaration with several declarators is usually equivalent to the corresponding sequence of declarations each with a single declarator. That is

```
T D1, D2, ... Dn;
```

is usually equivalent to

```
T D1; T D2; ... T Dn;
```

where T is a *decl-specifier-seq* and each Di is an *init-declarator*. One exception is when a name introduced by one of the *declarators* hides a type name used by the *decl-specifiers*, so that when the same *decl-specifiers* are used in a subsequent declaration, they do not have the same meaning, as in

```
struct S { ... };
S S, T;           // declare two instances of struct S
```

which is not equivalent to

```
struct S { ... };
S S;
S T;           // error
```

Another exception is when T is **auto** (??), for example:

```
auto i = 1, j = 2.0;    // error: deduced types for i and j do not match
```

as opposed to

```
auto i = 1;           // OK: i deduced to have type int
auto j = 2.0;          // OK: j deduced to have type double
```

— end note]

- <sup>4</sup> The optional *requires-clause* (??) in an *init-declarator* or *member-declarator* shall not be present when the declarator does not declare a function (??). When present after a declarator, the *requires-clause* is called the

*trailing requires-clause.* The trailing *requires-clause* introduces the *constraint-expression* that results from interpreting its *constraint-logical-or-expression* as a *constraint-expression*. [Example:

```
void f1(int a) requires true;           // OK
auto f2(int a) -> bool requires true;  // OK
auto f3(int a) requires true -> bool;   // error: requires-clause precedes trailing-return-type
void (*pf)() requires true;            // error: constraint on a variable
void g(int (*)() requires true);       // error: constraint on a parameter-declaration

auto* p = new void(*)(char) requires true; // error: not a function declaration
— end example]
```

<sup>5</sup> Declarators have the syntax

```
declarator:
    ptr-declarator
    noptr-declarator parameters-and-qualifiers trailing-return-type

ptr-declarator:
    noptr-declarator
    ptr-operator ptr-declarator

nopr-declarator:
    declarator-id attribute-specifier-seqopt
    noptr-declarator parameters-and-qualifiers
    noptr-declarator [ constant-expressionopt ] attribute-specifier-seqopt
    ( ptr-declarator )

parameters-and-qualifiers:
    ( parameter-declaration-clause ) cv-qualifier-seqopt
    ref-qualifieropt noexcept-specifieropt attribute-specifier-seqopt

trailing-return-type:
    -> type-id

ptr-operator:
    * attribute-specifier-seqopt cv-qualifier-seqopt
    & attribute-specifier-seqopt
    && attribute-specifier-seqopt
    nested-name-specifier * attribute-specifier-seqopt cv-qualifier-seqopt

cv-qualifier-seq:
    cv-qualifier cv-qualifier-seqopt

cv-qualifier:
    const
    volatile

ref-qualifier:
    &
    &&

declarator-id:
    . . . opt id-expression
```

## 11.1 Type names

[dcl.name]

- <sup>1</sup> To specify type conversions explicitly, and as an argument of `sizeof`, `alignof`, `new`, or `typeid`, the name of a type shall be specified. This can be done with a *type-id*, which is syntactically a declaration for a variable or function of that type that omits the name of the entity.

*type-id*:

*type-specifier-seq abstract-declarator<sub>opt</sub>*

*defining-type-id*:

*defining-type-specifier-seq abstract-declarator<sub>opt</sub>*

*abstract-declarator*:

*ptr-abstract-declarator*

*noptr-abstract-declarator<sub>opt</sub> parameters-and-qualifiers trailing-return-type*

*abstract-pack-declarator*

*ptr-abstract-declarator*:

*noptr-abstract-declarator*

*ptr-operator ptr-abstract-declarator<sub>opt</sub>*

*noptr-abstract-declarator*:

*noptr-abstract-declarator<sub>opt</sub> parameters-and-qualifiers*

*noptr-abstract-declarator<sub>opt</sub> [ constant-expression<sub>opt</sub> ] attribute-specifier-seq<sub>opt</sub>*

*( ptr-abstract-declarator )*

*abstract-pack-declarator*:

*noptr-abstract-pack-declarator*

*ptr-operator abstract-pack-declarator*

*noptr-abstract-pack-declarator*:

*noptr-abstract-pack-declarator parameters-and-qualifiers*

*noptr-abstract-pack-declarator [ constant-expression<sub>opt</sub> ] attribute-specifier-seq<sub>opt</sub>*

...

It is possible to identify uniquely the location in the *abstract-declarator* where the identifier would appear if the construction were a declarator in a declaration. The named type is then the same as the type of the hypothetical identifier. [*Example*:

```
int          // int i
int *        // int *pi
int *[3]     // int *p[3]
int (*)[3]   // int (*p3i)[3]
int *()      // int *f()
int (*)(double) // int (*pf)(double)
```

name respectively the types “`int`”, “pointer to `int`”, “array of 3 pointers to `int`”, “pointer to array of 3 `int`”, “function of (no parameters) returning pointer to `int`”, and “pointer to a function of (`double`) returning `int`”. — *end example*]

- <sup>2</sup> A type can also be named (often more easily) by using a `typedef` (??).

## 11.2 Ambiguity resolution

[dcl.ambig.res]

- <sup>1</sup> The ambiguity arising from the similarity between a function-style cast and a declaration mentioned in ?? can also occur in the context of a declaration. In that context, the choice is between a function declaration with a redundant set of parentheses around a parameter name and an object declaration with a function-style cast as the initializer. Just as for the ambiguities mentioned in ??, the resolution is to consider any construct

that could possibly be a declaration a declaration. [ *Note:* A declaration can be explicitly disambiguated by adding parentheses around the argument. The ambiguity can be avoided by use of copy-initialization or list-initialization syntax, or by use of a non-function-style cast. — *end note* ] [ *Example:*

```
struct S {
    S(int);
};

void foo(double a) {
    S w(int(a));           // function declaration
    S x(int());            // function declaration
    S y((int(a)));         // object declaration
    S y((int)a);           // object declaration
    S z = int(a);          // object declaration
}
```

— *end example* ]

- <sup>2</sup> An ambiguity can arise from the similarity between a function-style cast and a *type-id*. The resolution is that any construct that could possibly be a *type-id* in its syntactic context shall be considered a *type-id*. [ *Example:*

```
template <class T> struct X {};
template <int N> struct Y {};

X<int()> a;           // type-id
X<int(1)> b;          // expression (ill-formed)
Y<int()> c;           // type-id (ill-formed)
Y<int(1)> d;          // expression

void foo(signed char a) {
    sizeof(int());        // type-id (ill-formed)
    sizeof(int(a));       // expression
    sizeof(int(unsigned(a))); // type-id (ill-formed)

    (int())+1;            // type-id (ill-formed)
    (int(a))+1;           // expression
    (int(unsigned(a)))+1; // type-id (ill-formed)
}
```

— *end example* ]

- <sup>3</sup> Another ambiguity arises in a *parameter-declaration-clause* when a *type-name* is nested in parentheses. In this case, the choice is between the declaration of a parameter of type pointer to function and the declaration of a parameter with redundant parentheses around the *declarator-id*. The resolution is to consider the *type-name* as a *simple-type-specifier* rather than a *declarator-id*. [ *Example:*

```
class C { };
void f(int(C)) { }           // void f(int(*fp)(C c)) { }
                             // not: void f(int C) { }

int g(C);

void foo() {
    f(1);                  // error: cannot convert 1 to function pointer
```

```
f(g);           // OK
}
```

For another example,

```
class C { };
void h(int *(C[10]));           // void h(int *(_fp)(C _parm[10]));
                                // not: void h(int *C[10]);
— end example]
```

### 11.3 Meaning of declarators

[**dcl.meaning**]

- <sup>1</sup> A declarator contains exactly one *declarator-id*; it names the identifier that is declared. An *unqualified-id* occurring in a *declarator-id* shall be a simple *identifier* except for the declaration of some special functions (??, ??, ??, ??) and for the declaration of template specializations or partial specializations (??). When the *declarator-id* is qualified, the declaration shall refer to a previously declared member of the class or namespace to which the qualifier refers (or, in the case of a namespace, of an element of the inline namespace set of that namespace (??)) or to a specialization thereof; the member shall not merely have been introduced by a *using-declaration* in the scope of the class or namespace nominated by the *nested-name-specifier* of the *declarator-id*. The *nested-name-specifier* of a qualified *declarator-id* shall not begin with a *decltype-specifier*. [Note: If the qualifier is the global :: scope resolution operator, the *declarator-id* refers to a name declared in the global namespace scope. — end note] The optional *attribute-specifier-seq* following a *declarator-id* appertains to the entity that is declared.
- <sup>2</sup> A **static**, **thread\_local**, **extern**, **mutable**, **friend**, **inline**, **virtual**, **constexpr**, **explicit**, or **typedef** specifier applies directly to each *declarator-id* in an *init-declarator-list* or *member-declarator-list*; the type specified for each *declarator-id* depends on both the *decl-specifier-seq* and its *declarator*.
- <sup>3</sup> Thus, a declaration of a particular identifier has the form

T D

where T is of the form *attribute-specifier-seq<sub>opt</sub>* *decl-specifier-seq* and D is a declarator. Following is a recursive procedure for determining the type specified for the contained *declarator-id* by such a declaration.

- <sup>4</sup> First, the *decl-specifier-seq* determines a type. In a declaration

T D

the *decl-specifier-seq* T determines the type T. [Example: In the declaration

```
int unsigned i;
```

the type specifiers int unsigned determine the type “unsigned int” (??). — end example]

- <sup>5</sup> In a declaration *attribute-specifier-seq<sub>opt</sub>* T D where D is an unadorned identifier the type of this identifier is “T”.
- <sup>6</sup> In a declaration T D where D has the form

( D1 )

the type of the contained *declarator-id* is the same as that of the contained *declarator-id* in the declaration

T D1

Parentheses do not alter the type of the embedded *declarator-id*, but they can alter the binding of complex declarators.

### 11.3.1 Pointers

[dcl.ptr]

- <sup>1</sup> In a declaration T D where D has the form

$$\ast \text{ attribute-specifier-seq}_{opt} \text{ cv-qualifier-seq}_{opt} \text{ D1}$$

and the type of the identifier in the declaration T D1 is “*derived-declarator-type-list T*”, then the type of the identifier of D is “*derived-declarator-type-list cv-qualifier-seq* pointer to T”. The *cv-qualifiers* apply to the pointer and not to the object pointed to. Similarly, the optional *attribute-specifier-seq* (??) appertains to the pointer and not to the object pointed to.

- <sup>2</sup> [Example: The declarations

```
const int ci = 10, *pc = &ci, *const cpc = pc, **ppc;
int i, *p, *const cp = &i;
```

declare ci, a constant integer; pc, a pointer to a constant integer; cpc, a constant pointer to a constant integer; ppc, a pointer to a pointer to a constant integer; i, an integer; p, a pointer to integer; and cp, a constant pointer to integer. The value of ci, cpc, and cp cannot be changed after initialization. The value of pc can be changed, and so can the object pointed to by cp. Examples of some correct operations are

```
i = ci;
*cp = ci;
pc++;
pc = cpc;
pc = p;
ppc = &pc;
```

Examples of ill-formed operations are

```
ci = 1;           // error
ci++;            // error
*pc = 2;          // error
cp = &ci;          // error
cpc++;           // error
p = pc;           // error
ppc = &p;           // error
```

Each is unacceptable because it would either change the value of an object declared **const** or allow it to be changed through a cv-unqualified pointer later, for example:

```
*ppc = &ci;        // OK, but would make p point to ci because of previous error
*p = 5;            // clobber ci
— end example ]
```

- <sup>3</sup> See also ?? and ??.

- <sup>4</sup> [Note: Forming a pointer to reference type is ill-formed; see ?? . Forming a function pointer type is ill-formed if the function type has *cv-qualifiers* or a *ref-qualifier*; see ?? . Since the address of a bit-field (??) cannot be taken, a pointer can never point to a bit-field. — end note ]

### 11.3.2 References

[dcl.ref]

- <sup>1</sup> In a declaration T D where D has either of the forms

$$\& \text{ attribute-specifier-seq}_{opt} \text{ D1}$$

$$\&\& \text{ attribute-specifier-seq}_{opt} \text{ D1}$$

and the type of the identifier in the declaration T D1 is “*derived-declarator-type-list* T”, then the type of the identifier of D is “*derived-declarator-type-list* reference to T”. The optional *attribute-specifier-seq* appertains to the reference type. Cv-qualified references are ill-formed except when the cv-qualifiers are introduced through the use of a *typedef-name* (??, ??) or *decltype-specifier* (??), in which case the cv-qualifiers are ignored. [Example:

```
typedef int& A;
const A aref = 3; // ill-formed; lvalue reference to non-const initialized with rvalue
```

The type of `aref` is “lvalue reference to `int`”, not “lvalue reference to `const int`”. —end example] [Note: A reference can be thought of as a name of an object. —end note] A declarator that specifies the type “reference to *cv void*” is ill-formed.

- <sup>2</sup> A reference type that is declared using `&` is called an *lvalue reference*, and a reference type that is declared using `&&` is called an *rvalue reference*. Lvalue references and rvalue references are distinct types. Except where explicitly noted, they are semantically equivalent and commonly referred to as references.

- <sup>3</sup> [Example:

```
void f(double& a) { a += 3.14; }
// ...
double d = 0;
f(d);
```

declares `a` to be a reference parameter of `f` so the call `f(d)` will add 3.14 to `d`.

```
int v[20];
// ...
int& g(int i) { return v[i]; }
// ...
g(3) = 7;
```

declares the function `g()` to return a reference to an integer so `g(3)=7` will assign 7 to the fourth element of the array `v`. For another example,

```
struct link {
    link* next;
};

link* first;

void h(link*& p) { // p is a reference to pointer
    p->next = first;
    first = p;
    p = 0;
}

void k() {
    link* q = new link;
    h(q);
}
```

declares `p` to be a reference to a pointer to `link` so `h(q)` will leave `q` with the value zero. See also ???. —end example]

- <sup>4</sup> It is unspecified whether or not a reference requires storage (??).

- <sup>5</sup> There shall be no references to references, no arrays of references, and no pointers to references. The declaration of a reference shall contain an *initializer* (??) except when the declaration contains an explicit **extern** specifier (??), is a class member (??) declaration within a class definition, or is the declaration of a parameter or a return type (??); see ???. A reference shall be initialized to refer to a valid object or function. [Note: In particular, a null reference cannot exist in a well-defined program, because the only way to create such a reference would be to bind it to the “object” obtained by indirection through a null pointer, which causes undefined behavior. As described in ???, a reference cannot be bound directly to a bit-field. —end note]
- <sup>6</sup> If a *typedef-name* (??, ??) or a *decltype-specifier* (??) denotes a type TR that is a reference to a type T, an attempt to create the type “lvalue reference to *cv* TR” creates the type “lvalue reference to T”, while an attempt to create the type “rvalue reference to *cv* TR” creates the type TR. [Note: This rule is known as reference collapsing. —end note] [Example:

```

int i;
typedef int& LRI;
typedef int&& RRI;

LRI& r1 = i;           // r1 has the type int&
const LRI& r2 = i;    // r2 has the type int&
const LRI&& r3 = i;   // r3 has the type int&

RRI& r4 = i;           // r4 has the type int&
RRI&& r5 = 5;          // r5 has the type int&&

decltype(r2)& r6 = i;   // r6 has the type int&
decltype(r2)&& r7 = i;  // r7 has the type int&

— end example]

```

- <sup>7</sup> [Note: Forming a reference to function type is ill-formed if the function type has *cv-qualifiers* or a *ref-qualifier*; see ???. —end note]

### 11.3.3 Pointers to members

[dcl.mptr]

- <sup>1</sup> In a declaration T D where D has the form

$$\text{nested-name-specifier * attribute-specifier-seq}_{\text{opt}} \text{ cv-qualifier-seq}_{\text{opt}} \text{ D1}$$

and the *nested-name-specifier* denotes a class, and the type of the identifier in the declaration T D1 is “*derived-declarator-type-list* T”, then the type of the identifier of D is “*derived-declarator-type-list* cv-qualifier-seq pointer to member of class *nested-name-specifier* of type T”. The optional *attribute-specifier-seq* (??) appertains to the pointer-to-member.

- <sup>2</sup> [Example:

```

struct X {
    void f(int);
    int a;
};

struct Y;

int X::* pmi = &X::a;
void (Y::* pmf)(int) = &X::f;

```

```
double X::* pmd;
char Y::* pmc;
```

declares `pmi`, `pmf`, `pmd` and `pmc` to be a pointer to a member of `X` of type `int`, a pointer to a member of `X` of type `void(int)`, a pointer to a member of `X` of type `double` and a pointer to a member of `Y` of type `char` respectively. The declaration of `pmd` is well-formed even though `X` has no members of type `double`. Similarly, the declaration of `pmc` is well-formed even though `Y` is an incomplete type. `pmi` and `pmf` can be used like this:

```
X obj;
// ...
obj.*pmi = 7;           // assign 7 to an integer member of obj
(obj.*pmf)(7);         // call a function member of obj with the argument 7
— end example ]
```

- <sup>3</sup> A pointer to member shall not point to a static member of a class (??), a member with reference type, or “*cv void*”.

[*Note*: See also ?? and ?.?. The type “pointer to member” is distinct from the type “pointer”, that is, a pointer to member is declared only by the pointer-to-member declarator syntax, and never by the pointer declarator syntax. There is no “reference-to-member” type in C++. — *end note*]

#### 11.3.4 Arrays

[dcl.array]

- <sup>1</sup> In a declaration `T D` where `D` has the form

`D1 [ constant-expressionopt ] attribute-specifier-seqopt`

and the type of the identifier in the declaration `T D1` is “*derived-declarator-type-list T*”, then the type of the identifier of `D` is an array type; if the type of the identifier of `D` contains the `auto type-specifier`, the program is ill-formed. `T` is called the array *element type*; this type shall not be a reference type, *cv void*, a function type or an abstract class type. If the *constant-expression* (??) is present, it shall be a converted constant expression of type `std::size_t` and its value shall be greater than zero. The constant expression specifies the *bound* of (number of elements in) the array. If the value of the constant expression is `N`, the array has `N` elements numbered 0 to `N-1`, and the type of the identifier of `D` is “*derived-declarator-type-list array of N T*”. An object of array type contains a contiguously allocated non-empty set of `N` subobjects of type `T`. Except as noted below, if the constant expression is omitted, the type of the identifier of `D` is “*derived-declarator-type-list array of unknown bound of T*”, an incomplete object type. The type “*derived-declarator-type-list array of N T*” is a different type from the type “*derived-declarator-type-list array of unknown bound of T*”, see ?.?. Any type of the form “*cv-qualifier-seq array of N T*” is adjusted to “array of `N cv-qualifier-seq T`”, and similarly for “array of unknown bound of `T`”. The optional *attribute-specifier-seq* appertains to the array. [*Example*:

```
typedef int A[5], AA[2][3];
typedef const A CA;           // type is “array of 5 const int”
typedef const AA CAA;         // type is “array of 2 array of 3 const int”
```

— *end example*] [*Note*: An “array of `N cv-qualifier-seq T`” has *cv-qualified type*; see ?.?. — *end note*]

- <sup>2</sup> An array can be constructed from one of the fundamental types (except `void`), from a pointer, from a pointer to member, from a class, from an enumeration type, or from another array.
- <sup>3</sup> When several “array of” specifications are adjacent, a multidimensional array type is created; only the first of the constant expressions that specify the bounds of the arrays may be omitted. In addition to declarations in which an incomplete object type is allowed, an array bound may be omitted in some cases in the declaration

of a function parameter (??). An array bound may also be omitted when the declarator is followed by an *initializer* (??) or when a declarator for a static data member is followed by a *brace-or-equal-initializer* (??). In both cases the bound is calculated from the number of initial elements (say, N) supplied (??), and the type of the identifier of D is “array of N T”. Furthermore, if there is a preceding declaration of the entity in the same scope in which the bound was specified, an omitted array bound is taken to be the same as in that earlier declaration, and similarly for the definition of a static data member of a class.

<sup>4</sup> [ *Example*:

```
float fa[17], *afp[17];
```

declares an array of **float** numbers and an array of pointers to **float** numbers. — *end example*]

<sup>5</sup> [ *Example*:

```
int x3d[3][5][7];
```

declares an array of three elements, each of which is an array of five elements, each of which is an array of seven integers. The overall array can be viewed as a three-dimensional array of integers, with rank  $3 \times 5 \times 7$ . Any of the expressions **x3d**, **x3d[i]**, **x3d[i][j]**, **x3d[i][j][k]** can reasonably appear in an expression. The expression **x3d[i]** is equivalent to **\*(&x3d + i)**; in that expression, **x3d** is subject to the array-to-pointer conversion (??) and is first converted to a pointer to a 2-dimensional array with rank  $5 \times 7$  that points to the first element of **x3d**. Then **i** is added, which on typical implementations involves multiplying **i** by the length of the object to which the pointer points, which is **sizeof(int) × 5 × 7**. The result of the addition and indirection is an lvalue denoting the **i<sup>th</sup>** array element of **x3d** (an array of five arrays of seven integers). If there is another subscript, the same argument applies again, so **x3d[i][j]** is an lvalue denoting the **j<sup>th</sup>** array element of the **i<sup>th</sup>** array element of **x3d** (an array of seven integers), and **x3d[i][j][k]** is an lvalue denoting the **k<sup>th</sup>** array element of the **j<sup>th</sup>** array element of the **i<sup>th</sup>** array element of **x3d** (an integer). — *end example*] [ *Note*: The first subscript in the declaration helps determine the amount of storage consumed by an array but plays no other part in subscript calculations. — *end note*]

<sup>6</sup> [ *Example*:

```
extern int x[10];
struct S {
    static int y[10];
};

int x[];                      // OK: bound is 10
int S::y[];                    // OK: bound is 10

void f() {
    extern int x[];
    int i = sizeof(x);      // error: incomplete object type
}
```

— *end example*]

<sup>7</sup> [ *Note*: Conversions affecting expressions of array type are described in ???. Objects of array types cannot be modified, see ???. — *end note*]

<sup>8</sup> [ *Note*: Except where it has been declared for a class (??), the subscript operator [] is interpreted in such a way that **E1[E2]** is identical to **\*((E1)+(E2))** (??). Because of the conversion rules that apply to +, if **E1** is an array and **E2** an integer, then **E1[E2]** refers to the **E2**-th member of **E1**. Therefore, despite its asymmetric appearance, subscripting is a commutative operation. — *end note*]

### 11.3.5 Functions

[dcl.fct]

- 1 In a declaration T D where D has the form

```
D1 ( parameter-declaration-clause ) cv-qualifier-seqopt
    ref-qualifieropt noexcept-specifieropt attribute-specifier-seqopt
```

and the type of the contained *declarator-id* in the declaration T D1 is “*derived-declarator-type-list* T”, the type of the *declarator-id* in D is “*derived-declarator-type-list* noexcept<sub>opt</sub> function of (parameter-declaration-clause) cv-qualifier-seq<sub>opt</sub> ref-qualifier<sub>opt</sub> returning T”, where the optional noexcept is present if and only if the exception specification (??) is non-throwing. The optional attribute-specifier-seq appertains to the function type.

- 2 In a declaration T D where D has the form

```
D1 ( parameter-declaration-clause ) cv-qualifier-seqopt
    ref-qualifieropt noexcept-specifieropt attribute-specifier-seqopt trailing-return-type
```

and the type of the contained *declarator-id* in the declaration T D1 is “*derived-declarator-type-list* T”, T shall be the single *type-specifier* auto. The type of the *declarator-id* in D is “*derived-declarator-type-list* noexcept<sub>opt</sub> function of (parameter-declaration-clause) cv-qualifier-seq<sub>opt</sub> ref-qualifier<sub>opt</sub> returning U”, where U is the type specified by the trailing-return-type, and where the optional noexcept is present if and only if the exception specification is non-throwing. The optional attribute-specifier-seq appertains to the function type.

- 3 A type of either form is a *function type*.<sup>102</sup>

*parameter-declaration-clause*:

```
parameter-declaration-listopt ...opt
parameter-declaration-list , ...
```

*parameter-declaration-list*:

```
parameter-declaration
parameter-declaration-list , parameter-declaration
```

*parameter-declaration*:

```
attribute-specifier-seqopt decl-specifier-seq declarator
attribute-specifier-seqopt decl-specifier-seq declarator = initializer-clause
attribute-specifier-seqopt decl-specifier-seq abstract-declaratoropt
attribute-specifier-seqopt decl-specifier-seq abstract-declaratoropt = initializer-clause
```

The optional attribute-specifier-seq in a *parameter-declaration* appertains to the parameter.

- 4 The *parameter-declaration-clause* determines the arguments that can be specified, and their processing, when the function is called. [Note: The *parameter-declaration-clause* is used to convert the arguments specified on the function call; see ???. —end note] If the *parameter-declaration-clause* is empty, the function takes no arguments. A parameter list consisting of a single unnamed parameter of non-dependent type void is equivalent to an empty parameter list. Except for this special case, a parameter shall not have type cv void. If the *parameter-declaration-clause* terminates with an ellipsis or a function parameter pack (??), the number of arguments shall be equal to or greater than the number of parameters that do not have a default argument and are not function parameter packs. Where syntactically correct and where “...” is not part of an *abstract-declarator*, “, ...” is synonymous with “...”. [Example: The declaration

```
int printf(const char*, ...);
```

declares a function that can be called with varying numbers and types of arguments.

```
printf("hello world");
```

---

<sup>102)</sup> As indicated by syntax, cv-qualifiers are a significant component in function return types.

```
printf("a=%d b=%d", a, b);
```

However, the first argument must be of a type that can be converted to a `const char*` — *end example*  
 [ *Note*: The standard header `<cstdarg>` contains a mechanism for accessing arguments passed using the ellipsis (see ?? and ??). — *end note* ]

- 5 The type of a function is determined using the following rules. The type of each parameter (including function parameter packs) is determined from its own *decl-specifier-seq* and *declarator*. After determining the type of each parameter, any parameter of type “array of T” or of function type T is adjusted to be “pointer to T”. After producing the list of parameter types, any top-level *cv-qualifiers* modifying a parameter type are deleted when forming the function type. The resulting list of transformed parameter types and the presence or absence of the ellipsis or a function parameter pack is the function’s *parameter-type-list*.  
 [ *Note*: This transformation does not affect the types of the parameters. For example, `int(*)(const int p, decltype(p)*)` and `int(*)(int, const int*)` are identical types. — *end note* ]
- 6 A function type with a *cv-qualifier-seq* or a *ref-qualifier* (including a type named by *typedef-name* (??, ??)) shall appear only as:

- (6.1) — the function type for a non-static member function,
- (6.2) — the function type to which a pointer to member refers,
- (6.3) — the top-level function type of a function *typedef declaration* or *alias-declaration*,
- (6.4) — the *type-id* in the default argument of a *type-parameter* (??), or
- (6.5) — the *type-id* of a *template-argument* for a *type-parameter* (??).

[ *Example*:

```
typedef int FIC(int) const;
FIC f;           // ill-formed: does not declare a member function
struct S {
    FIC f;       // OK
};
FIC S::*pm = &S::f; // OK
— end example ]
```

- 7 The effect of a *cv-qualifier-seq* in a function declarator is not the same as adding cv-qualification on top of the function type. In the latter case, the cv-qualifiers are ignored. [ *Note*: A function type that has a *cv-qualifier-seq* is not a cv-qualified type; there are no cv-qualified function types. — *end note* ] [ *Example*:

```
typedef void F();
struct S {
    const F f;     // OK: equivalent to: void f();
};
— end example ]
```

- 8 The return type, the *parameter-type-list*, the *ref-qualifier*, the *cv-qualifier-seq*, and the exception specification, but not the default arguments (??) or the trailing *requires-clause* (??), are part of the function type. [ *Note*: Function types are checked during the assignments and initializations of pointers to functions, references to functions, and pointers to member functions. — *end note* ]

- 9 [ *Example*: The declaration

```
int fseek(FILE*, long, int);
```

declares a function taking three arguments of the specified types, and returning `int` (??). — *end example*]

- 10 A single name can be used for several different functions in a single scope; this is function overloading (??). All declarations for a function shall have equivalent return types, parameter-type-lists, and *requires-clauses* (??).
- 11 Functions shall not have a return type of type array or function, although they may have a return type of type pointer or reference to such things. There shall be no arrays of functions, although there can be arrays of pointers to functions.
- 12 Types shall not be defined in return or parameter types. The type of a parameter or the return type for a function definition shall not be an incomplete (possibly cv-qualified) class type in the context of the function definition unless the function is deleted (??).
- 13 A `typedef` of function type may be used to declare a function but shall not be used to define a function (??). [ *Example*:

```
typedef void F();
F fv;           // OK: equivalent to void fv();
F fv { }        // ill-formed
void fv() { }   // OK: definition of fv
```

— *end example*]

- 14 An identifier can optionally be provided as a parameter name; if present in a function definition (??), it names a parameter. [ *Note*: In particular, parameter names are also optional in function definitions and names used for a parameter in different declarations and the definition of a function need not be the same. If a parameter name is present in a function declaration that is not a definition, it cannot be used outside of its function declarator because that is the extent of its potential scope (??). — *end note*]

- 15 [ *Example*: The declaration

```
int i,
    *pi,
    f(),
    *fpi(int),
    (*pif)(const char*, const char*),
    (*fpif(int))(int);
```

declares an integer `i`, a pointer `pi` to an integer, a function `f` taking no arguments and returning an integer, a function `fpi` taking an integer argument and returning a pointer to an integer, a pointer `pif` to a function which takes two pointers to constant characters and returns an integer, a function `fpif` taking an integer argument and returning a pointer to a function that takes an integer argument and returns an integer. It is especially useful to compare `fpi` and `pif`. The binding of `*fpi(int)` is `*(fpi(int))`, so the declaration suggests, and the same construction in an expression requires, the calling of a function `fpi`, and then using indirection through the (pointer) result to yield an integer. In the declarator `(*pif)(const char*, const char*)`, the extra parentheses are necessary to indicate that indirection through a pointer to a function yields a function, which is then called. — *end example*] [ *Note*: *Typedefs* and *trailing-return-types* are sometimes convenient when the return type of a function is complex. For example, the function `fpif` above could have been declared

```
typedef int IFUNC(int);
IFUNC* fpif(int);
```

or

```
auto fpif(int)->int(*)(int);
```

A *trailing-return-type* is most useful for a type that would be more complicated to specify before the *declarator-id*:

```
template <class T, class U> auto add(T t, U u) -> decltype(t + u);
```

rather than

```
template <class T, class U> decltype((*(T*)0) + (*(U*)0)) add(T t, U u);
```

— *end note*]

<sup>16</sup> A *non-template function* is a function that is not a function template specialization. [Note: A function template is not a function. — *end note*]

<sup>17</sup> A *declarator-id* or *abstract-declarator* containing an ellipsis shall only be used in a *parameter-declaration*. Such a *parameter-declaration* is a parameter pack (??). When it is part of a *parameter-declaration-clause*, the parameter pack is a function parameter pack (??). [Note: Otherwise, the *parameter-declaration* is part of a *template-parameter-list* and the parameter pack is a template parameter pack; see ?? . — *end note*] A function parameter pack is a pack expansion (??). [Example:

```
template<typename... T> void f(T (* ...t)(int, int));
```

```
int add(int, int);
float subtract(int, int);
```

```
void g() {
    f(add, subtract);
}
```

— *end example*]

<sup>18</sup> There is a syntactic ambiguity when an ellipsis occurs at the end of a *parameter-declaration-clause* without a preceding comma. In this case, the ellipsis is parsed as part of the *abstract-declarator* if the type of the parameter either names a template parameter pack that has not been expanded or contains `auto`; otherwise, it is parsed as part of the *parameter-declaration-clause*.<sup>103</sup>

### 11.3.6 Default arguments

[dcl.fct.default]

<sup>1</sup> If an *initializer-clause* is specified in a *parameter-declaration* this *initializer-clause* is used as a default argument. Default arguments will be used in calls where trailing arguments are missing.

<sup>2</sup> [Example: The declaration

```
void point(int = 3, int = 4);
```

declares a function that can be called with zero, one, or two arguments of type `int`. It can be called in any of these ways:

```
point(1,2); point(1); point();
```

The last two calls are equivalent to `point(1,4)` and `point(3,4)`, respectively. — *end example*]

<sup>3</sup> A default argument shall be specified only in the *parameter-declaration-clause* of a function declaration or *lambda-declarator* or in a *template-parameter* (??); in the latter case, the *initializer-clause* shall be an *assignment-expression*. A default argument shall not be specified for a parameter pack. If it is specified in a

---

(103) One can explicitly disambiguate the parse either by introducing a comma (so the ellipsis will be parsed as part of the *parameter-declaration-clause*) or by introducing a name for the parameter (so the ellipsis will be parsed as part of the *declarator-id*).

*parameter-declaration-clause*, it shall not occur within a *declarator* or *abstract-declarator* of a *parameter-declaration*.<sup>104</sup>

- <sup>4</sup> For non-template functions, default arguments can be added in later declarations of a function in the same scope. Declarations in different scopes have completely distinct sets of default arguments. That is, declarations in inner scopes do not acquire default arguments from declarations in outer scopes, and vice versa. In a given function declaration, each parameter subsequent to a parameter with a default argument shall have a default argument supplied in this or a previous declaration or shall be a function parameter pack. A default argument shall not be redefined by a later declaration (not even to the same value). [ *Example*:

```

void g(int = 0, ...);           // OK, ellipsis is not a parameter so it can follow
                                // a parameter with a default argument

void f(int, int);
void f(int, int = 7);
void h() {
    f(3);                      // OK, calls f(3, 7)
    void f(int = 1, int);       // error: does not use default from surrounding scope
}
void m() {
    void f(int, int);          // has no defaults
    f(4);                      // error: wrong number of arguments
    void f(int, int = 5);       // OK
    f(4);                      // OK, calls f(4, 5);
    void f(int, int = 5);       // error: cannot redefine, even to same value
}
void n() {
    f(6);                      // OK, calls f(6, 7)
}
```

— *end example*] For a given inline function defined in different translation units, the accumulated sets of default arguments at the end of the translation units shall be the same; see ???. If a friend declaration specifies a default argument expression, that declaration shall be a definition and shall be the only declaration of the function or function template in the translation unit.

- <sup>5</sup> The default argument has the same semantic constraints as the initializer in a declaration of a variable of the parameter type, using the copy-initialization semantics (??). The names in the default argument are bound, and the semantic constraints are checked, at the point where the default argument appears. Name lookup and checking of semantic constraints for default arguments in function templates and in member functions of class templates are performed as described in ???. [ *Example*: In the following code, *g* will be called with the value *f*(2):

```

int a = 1;
int f(int);
int g(int x = f(a));           // default argument: f(::a)

void h() {
    a = 2;
    {
        int a = 3;
```

---

<sup>104)</sup> This means that default arguments cannot appear, for example, in declarations of pointers to functions, references to functions, or **typedef** declarations.

```

    g();                      // g(f(::a))
}
}

```

—end example] [Note: In member function declarations, names in default arguments are looked up as described in ???. Access checking applies to names in default arguments as described in ???. —end note]

- 6 Except for member functions of class templates, the default arguments in a member function definition that appears outside of the class definition are added to the set of default arguments provided by the member function declaration in the class definition; the program is ill-formed if a default constructor (??), copy or move constructor, or copy or move assignment operator (??) is so declared. Default arguments for a member function of a class template shall be specified on the initial declaration of the member function within the class template. [Example:

```

class C {
    void f(int i = 3);
    void g(int i, int j = 99);
};

void C::f(int i = 3) {}           // error: default argument already specified in class scope
void C::g(int i = 88, int j) {} // in this translation unit, C::g can be called with no argument

```

—end example]

- 7 [Note: A local variable cannot be odr-used (??) in a default argument. —end note] [Example:

```

void f() {
    int i;
    extern void g(int x = i);           // error
    extern void h(int x = sizeof(i)); // OK
    // ...
}

```

—end example]

- 8 [Note: The keyword `this` may not appear in a default argument of a member function; see ???. [Example:

```

class A {
    void f(A* p = this) {}           // error
};

```

—end example] —end note]

- 9 A default argument is evaluated each time the function is called with no argument for the corresponding parameter. A parameter shall not appear as a potentially-evaluated expression in a default argument. Parameters of a function declared before a default argument are in scope and can hide namespace and class member names. [Example:

```

int a;
int f(int a, int b = a);           // error: parameter a used as default argument
typedef int I;
int g(float I, int b = I(2));     // error: parameter I found
int h(int a, int b = sizeof(a)); // OK, unevaluated operand

```

—end example] A non-static member shall not appear in a default argument unless it appears as the *id-expression* of a class member access expression (??) or unless it is used to form a pointer to member (??).

[*Example*: The declaration of `X::mem1()` in the following example is ill-formed because no object is supplied for the non-static member `X::a` used as an initializer.

```
int b;
class X {
    int a;
    int mem1(int i = a);           // error: non-static member a used as default argument
    int mem2(int i = b);           // OK; use X::b
    static int b;
};
```

The declaration of `X::mem2()` is meaningful, however, since no object is needed to access the static member `X::b`. Classes, objects, and members are described in ???. — *end example*] A default argument is not part of the type of a function. [*Example*:

```
int f(int = 0);

void h() {
    int j = f(1);
    int k = f();           // OK, means f(0)
}

int (*p1)(int) = &f;
int (*p2)() = &f;          // error: type mismatch
```

— *end example*] When a declaration of a function is introduced by way of a *using-declaration* (??), any default argument information associated with the declaration is made known as well. If the function is redeclared thereafter in the namespace with additional default arguments, the additional arguments are also known at any point following the redeclaration where the *using-declaration* is in scope.

- <sup>10</sup> A virtual function call (??) uses the default arguments in the declaration of the virtual function determined by the static type of the pointer or reference denoting the object. An overriding function in a derived class does not acquire default arguments from the function it overrides. [*Example*:

```
struct A {
    virtual void f(int a = 7);
};

struct B : public A {
    void f(int a);
};

void m() {
    B* pb = new B;
    A* pa = pb;
    pa->f();           // OK, calls pa->B::f(7)
    pb->f();           // error: wrong number of arguments for B::f()
}
```

— *end example*]

## 11.4 Function definitions

[dcl.fct.def]

### 11.4.1 In general

[dcl.fct.def.general]

<sup>1</sup> Function definitions have the form

*function-definition:*

*attribute-specifier-seq<sub>opt</sub>* *decl-specifier-seq<sub>opt</sub>* *declarator* *virt-specifier-seq<sub>opt</sub>* *function-body*

*attribute-specifier-seq<sub>opt</sub>* *decl-specifier-seq<sub>opt</sub>* *declarator* *requires-clause* *function-body*

*function-body:*

*ctor-initializer<sub>opt</sub>* *compound-statement*

*function-try-block*

*= default ;*

*= delete ;*

Any informal reference to the body of a function should be interpreted as a reference to the non-terminal *function-body*. The optional *attribute-specifier-seq* in a *function-definition* appertains to the function. A *virt-specifier-seq* can be part of a *function-definition* only if it is a *member-declaration* (??).

- 2 In a *function-definition*, either `void declarator ;` or `declarator ;` shall be a well-formed function declaration as described in ???. A function shall be defined only in namespace or class scope.
- 3 [ *Example*: A simple example of a complete function definition is

```
int max(int a, int b, int c) {
    int m = (a > b) ? a : b;
    return (m > c) ? m : c;
}
```

Here `int` is the *decl-specifier-seq*; `max(int a, int b, int c)` is the *declarator*; `{ /* ... */ }` is the *function-body*. — *end example* ]

- 4 A *ctor-initializer* is used only in a constructor; see ?? and ??.
- 5 [ *Note*: A *cv-qualifier-seq* affects the type of `this` in the body of a member function; see ???. — *end note* ]
- 6 [ *Note*: Unused parameters need not be named. For example,

```
void print(int a, int) {
    std::printf("a = %d\n", a);
}
```

— *end note* ]

- 7 In the *function-body*, a *function-local predefined variable* denotes a block-scope object of static storage duration that is implicitly defined (see ??).
- 8 The function-local predefined variable `__func__` is defined as if a definition of the form

```
static const char __func__[] = "function-name";
```

had been provided, where *function-name* is an implementation-defined string. It is unspecified whether such a variable has an address distinct from that of any other object in the program.<sup>105</sup> [ *Example*:

```
struct S {
    S() : s(__func__) {} // OK
    const char* s;
};

void f(const char* s = __func__); // error: __func__ is undeclared

— end example ]
```

<sup>105</sup>) Implementations are permitted to provide additional predefined variables with names that are reserved to the implementation (??). If a predefined variable is not odr-used (??), its string value need not be present in the program image.

### 11.4.2 Explicitly-defaulted functions

[dcl.fct.def.default]

- <sup>1</sup> A function definition whose *function-body* is of the form = `default` ; is called an *explicitly-defaulted* definition. A function that is explicitly defaulted shall
  - (1.1) — be a special member function or a comparison operator (??, ??, ??), and
  - (1.2) — not have default arguments.
- <sup>2</sup> The type  $T_1$  of an explicitly defaulted function  $F$  is allowed to differ from the type  $T_2$  it would have had if it were implicitly declared, as follows:
  - (2.1) —  $T_1$  and  $T_2$  may have differing *ref-qualifiers*; and
  - (2.2) — if  $T_2$  has a parameter of type `const C&`, the corresponding parameter of  $T_1$  may be of type `C&`.

If  $T_1$  differs from  $T_2$  in any other way, then:

- (2.3) — if  $F$  is an assignment operator, and the return type of  $T_1$  differs from the return type of  $T_2$  or  $T_1$ 's parameter type is not a reference, the program is ill-formed;
  - (2.4) — otherwise, if  $F$  is explicitly defaulted on its first declaration, it is defined as deleted;
  - (2.5) — otherwise, the program is ill-formed.
- <sup>3</sup> An explicitly-defaulted function that is not defined as deleted may be declared `constexpr` only if it would have been implicitly declared as `constexpr`. If a function is explicitly defaulted on its first declaration, it is implicitly considered to be `constexpr` if the implicit declaration would be.

- <sup>4</sup> [ *Example*:

```
struct S {
    constexpr S() = default;           // ill-formed: implicit S() is not constexpr
    S(int a = 0) = default;           // ill-formed: default argument
    void operator=(const S&) = default; // ill-formed: non-matching return type
    ~S() noexcept(false) = default;   // deleted: exception specification does not match

private:
    int i;
    S(S&);                         // OK: private copy constructor
};

S::S(S&) = default;               // OK: defines copy constructor

— end example ]
```

- <sup>5</sup> Explicitly-defaulted functions and implicitly-declared functions are collectively called *defaulted* functions, and the implementation shall provide implicit definitions for them (?? ??, ??), which might mean defining them as deleted. A function is *user-provided* if it is user-declared and not explicitly defaulted or deleted on its first declaration. A user-provided explicitly-defaulted function (i.e., explicitly defaulted after its first declaration) is defined at the point where it is explicitly defaulted; if such a function is implicitly defined as deleted, the program is ill-formed. [ *Note*: Declaring a function as defaulted after its first declaration can provide efficient execution and concise definition while enabling a stable binary interface to an evolving code base. — *end note* ]

- <sup>6</sup> [ *Example*:

```
struct trivial {
    trivial() = default;
    trivial(const trivial&) = default;
    trivial(trivial&&) = default;
```

```

trivial& operator=(const trivial&) = default;
trivial& operator=(trivial&&) = default;
~trivial() = default;
};

struct nontrivial1 {
    nontrivial1();
};

nontrivial1::nontrivial1() = default; // not first declaration
— end example]
```

### 11.4.3 Deleted definitions

[**dcl.fct.def.delete**]

- <sup>1</sup> A function definition whose *function-body* is of the form `= delete` ; is called a *deleted definition*. A function with a deleted definition is also called a *deleted function*.
- <sup>2</sup> A program that refers to a deleted function implicitly or explicitly, other than to declare it, is ill-formed. [ *Note*: This includes calling the function implicitly or explicitly and forming a pointer or pointer-to-member to the function. It applies even for references in expressions that are not potentially-evaluated. If a function is overloaded, it is referenced only if the function is selected by overload resolution. The implicit odr-use (??) of a virtual function does not, by itself, constitute a reference. — *end note* ]
- <sup>3</sup> [ *Example*: One can enforce non-default-initialization and non-integral initialization with

```

struct onlydouble {
    onlydouble() = delete; // OK, but redundant
    onlydouble(std::intmax_t) = delete;
    onlydouble(double);
};

— end example]
```

[ *Example*: One can prevent use of a class in certain *new-expressions* by using deleted definitions of a user-declared `operator new` for that class.

```

struct sometype {
    void* operator new(std::size_t) = delete;
    void* operator new[](std::size_t) = delete;
};

sometype* p = new sometype; // error, deleted class operator new
sometype* q = new sometype[3]; // error, deleted class operator new[]

— end example]
```

[ *Example*: One can make a class uncopyable, i.e., move-only, by using deleted definitions of the copy constructor and copy assignment operator, and then providing defaulted definitions of the move constructor and move assignment operator.

```

struct moveonly {
    moveonly() = default;
    moveonly(const moveonly&) = delete;
    moveonly(moveonly&&) = default;
    moveonly& operator=(const moveonly&) = delete;
    moveonly& operator=(moveonly&&) = default;
```

```

~moveonly() = default;
};

moveonly* p;
moveonly q(*p);           // error, deleted copy constructor
— end example]

```

- <sup>4</sup> A deleted function is implicitly an inline function (??). [Note: The one-definition rule (??) applies to deleted definitions. — end note] A deleted definition of a function shall be the first declaration of the function or, for an explicit specialization of a function template, the first declaration of that specialization. An implicitly declared allocation or deallocation function (??) shall not be defined as deleted. [Example:

```

struct sometype {
    sometype();
};

sometype::sometype() = delete; // ill-formed; not first declaration
— end example]

```

## 11.5 Structured binding declarations

[dcl.struct.bind]

- <sup>1</sup> A structured binding declaration introduces the *identifiers*  $v_0, v_1, v_2, \dots$  of the *identifier-list* as names (??), called *structured bindings*. Let  $cv$  denote the *cv-qualifiers* in the *decl-specifier-seq*. First, a variable with a unique name  $e$  is introduced. If the *assignment-expression* in the *initializer* has array type  $A$  and no *ref-qualifier* is present,  $e$  has type  $cv A$  and each element is copy-initialized or direct-initialized from the corresponding element of the *assignment-expression* as specified by the form of the *initializer*. Otherwise,  $e$  is defined as-if by

```
attribute-specifier-seqopt decl-specifier-seq ref-qualifieropt e initializer;
```

where the declaration is never interpreted as a function declaration and the parts of the declaration other than the *declarator-id* are taken from the corresponding structured binding declaration. The type of the *id-expression*  $e$  is called  $E$ . [Note:  $E$  is never a reference type (??). — end note]

- <sup>2</sup> If  $E$  is an array type with element type  $T$ , the number of elements in the *identifier-list* shall be equal to the number of elements of  $E$ . Each  $v_i$  is the name of an lvalue that refers to the element  $i$  of the array and whose type is  $T$ ; the referenced type is  $T$ . [Note: The top-level *cv-qualifiers* of  $T$  are  $cv$ . — end note] [Example:

```

auto f() -> int(&)[2];
auto [ x, y ] = f();           // x and y refer to elements in a copy of the array return value
auto& [ xr, yr ] = f();       // xr and yr refer to elements in the array referred to by f's return value
— end example]

```

- <sup>3</sup> Otherwise, if the *qualified-id*  $\text{std}::\text{tuple\_size}\langle E \rangle$  names a complete type, the expression  $\text{std}::\text{tuple\_size}\langle E \rangle::\text{value}$  shall be a well-formed integral constant expression and the number of elements in the *identifier-list* shall be equal to the value of that expression. The *unqualified-id*  $\text{get}$  is looked up in the scope of  $E$  by class member access lookup (??), and if that finds at least one declaration, the initializer is  $e.\text{get}\langle i \rangle()$ . Otherwise, the initializer is  $\text{get}\langle i \rangle(e)$ , where  $\text{get}$  is looked up in the associated namespaces (??). In either case,  $\text{get}\langle i \rangle$  is interpreted as a *template-id*. [Note: Ordinary unqualified lookup (??) is not performed. — end note] In either case,  $e$  is an lvalue if the type of the entity  $e$  is an lvalue reference and an xvalue otherwise. Given the type  $T_i$  designated by  $\text{std}::\text{tuple_element}\langle i, E \rangle::\text{type}$ , variables are introduced with unique names  $r_i$  of type “reference to  $T_i$ ” initialized with the initializer (??), where the reference is an

lvalue reference if the initializer is an lvalue and an rvalue reference otherwise. Each  $v_i$  is the name of an lvalue of type  $T_i$  that refers to the object bound to  $r_i$ ; the referenced type is  $T_i$ .

- <sup>4</sup> Otherwise, all of E’s non-static data members shall be public direct members of E or of the same unambiguous public base class of E, E shall not have an anonymous union member, and the number of elements in the *identifier-list* shall be equal to the number of non-static data members of E. Designating the non-static data members of E as  $m_0, m_1, m_2, \dots$  (in declaration order), each  $v_i$  is the name of an lvalue that refers to the member  $m_i$  of e and whose type is  $cv T_i$ , where  $T_i$  is the declared type of that member; the referenced type is  $cv T_i$ . The lvalue is a bit-field if that member is a bit-field. [ *Example*:

```
struct S { int x1 : 2; volatile double y1; };
S f();
const auto [ x, y ] = f();
```

The type of the *id-expression* x is “`const int`”, the type of the *id-expression* y is “`const volatile double`”. — *end example*]

## 11.6 Initializers

[dcl.init]

- <sup>1</sup> The process of initialization described in this subclause applies to all initializations regardless of syntactic context, including the initialization of a function parameter (??), the initialization of a return value (??), or when an initializer follows a declarator.

```
initializer:
brace-or-equal-initializer
( expression-list )

brace-or-equal-initializer:
= initializer-clause
braced-init-list

initializer-clause:
assignment-expression
braced-init-list

braced-init-list:
{ initializer-list ,opt }
{ designated-initializer-list ,opt }
{ }

initializer-list:
initializer-clause ...opt
initializer-list , initializer-clause ...opt

designated-initializer-list:
designated-initializer-clause
designated-initializer-list , designated-initializer-clause

designated-initializer-clause:
designator brace-or-equal-initializer

designator:
. identifier

expr-or-braced-init-list:
expression
braced-init-list
```

[*Note*: The rules in this subclause apply even if the grammar permits only the *brace-or-equal-initializer* form of *initializer* in a given context. — *end note*]

- 2 Except for objects declared with the `constexpr` specifier, for which see ??, an *initializer* in the definition of a variable can consist of arbitrary expressions involving literals and previously declared variables and functions, regardless of the variable's storage duration. [ *Example*:

```
int f(int);
int a = 2;
int b = f(a);
int c(b);

— end example]
```

- 3 [*Note*: Default arguments are more restricted; see ?? . — *end note*]
- 4 [*Note*: The order of initialization of variables with static storage duration is described in ?? and ?? . — *end note*]

- 5 A declaration of a block-scope variable with external or internal linkage that has an *initializer* is ill-formed.

- 6 To *zero-initialize* an object or reference of type T means:

- (6.1) — if T is a scalar type (??), the object is initialized to the value obtained by converting the integer literal 0 (zero) to T;<sup>106</sup>
- (6.2) — if T is a (possibly cv-qualified) non-union class type, its padding bits (??) are initialized to zero bits and each non-static data member, each non-virtual base class subobject, and, if the object is not a base class subobject, each virtual base class subobject is zero-initialized;
- (6.3) — if T is a (possibly cv-qualified) union type, its padding bits (??) are initialized to zero bits and the object's first non-static named data member is zero-initialized;
- (6.4) — if T is an array type, each element is zero-initialized;
- (6.5) — if T is a reference type, no initialization is performed.

- 7 To *default-initialize* an object of type T means:

- (7.1) — If T is a (possibly cv-qualified) class type (??), constructors are considered. The applicable constructors are enumerated (??), and the best one for the *initializer* () is chosen through overload resolution (??). The constructor thus selected is called, with an empty argument list, to initialize the object.
- (7.2) — If T is an array type, each element is default-initialized.
- (7.3) — Otherwise, no initialization is performed.

A class type T is *const-default-constructible* if default-initialization of T would invoke a user-provided constructor of T (not inherited from a base class) or if

- (7.4) — each direct non-variant non-static data member M of T has a default member initializer or, if M is of class type X (or array thereof), X is const-default-constructible,
- (7.5) — if T is a union with at least one non-static data member, exactly one variant member has a default member initializer,
- (7.6) — if T is not a union, for each anonymous union member with at least one non-static data member (if any), exactly one non-static data member has a default member initializer, and
- (7.7) — each potentially constructed base class of T is const-default-constructible.

---

<sup>106</sup>) As specified in ??, converting an integer literal whose value is 0 to a pointer type results in a null pointer value.

If a program calls for the default-initialization of an object of a const-qualified type T, T shall be a const-default-constructible class type or array thereof.

<sup>8</sup> To *value-initialize* an object of type T means:

- (8.1) — if T is a (possibly cv-qualified) class type (??) with either no default constructor (??) or a default constructor that is user-provided or deleted, then the object is default-initialized;
- (8.2) — if T is a (possibly cv-qualified) class type without a user-provided or deleted default constructor, then the object is zero-initialized and the semantic constraints for default-initialization are checked, and if T has a non-trivial default constructor, the object is default-initialized;
- (8.3) — if T is an array type, then each element is value-initialized;
- (8.4) — otherwise, the object is zero-initialized.

<sup>9</sup> A program that calls for default-initialization or value-initialization of an entity of reference type is ill-formed.

<sup>10</sup> [Note: Every object of static storage duration is zero-initialized at program startup before any other initialization takes place. In some cases, additional initialization is done later. —end note]

<sup>11</sup> An object whose initializer is an empty set of parentheses, i.e., (), shall be value-initialized.

[Note: Since () is not permitted by the syntax for *initializer*,

```
X a();
```

is not the declaration of an object of class X, but the declaration of a function taking no argument and returning an X. The form () is permitted in certain other initialization contexts (??, ??, ??). —end note]

<sup>12</sup> If no initializer is specified for an object, the object is default-initialized. When storage for an object with automatic or dynamic storage duration is obtained, the object has an *indeterminate value*, and if no initialization is performed for the object, that object retains an indeterminate value until that value is replaced (??). [Note: Objects with static or thread storage duration are zero-initialized, see ??.. —end note] If an indeterminate value is produced by an evaluation, the behavior is undefined except in the following cases:

(12.1) — If an indeterminate value of unsigned narrow character type (??) or std::byte type (??) is produced by the evaluation of:

(12.1.1) — the second or third operand of a conditional expression (??),

(12.1.2) — the right operand of a comma expression (??),

(12.1.3) — the operand of a cast or conversion (??, ??, ??, ??) to an unsigned narrow character type or std::byte type (??), or

(12.1.4) — a discarded-value expression (??),

then the result of the operation is an indeterminate value.

(12.2) — If an indeterminate value of unsigned narrow character type or std::byte type is produced by the evaluation of the right operand of a simple assignment operator (??) whose first operand is an lvalue of unsigned narrow character type or std::byte type, an indeterminate value replaces the value of the object referred to by the left operand.

(12.3) — If an indeterminate value of unsigned narrow character type is produced by the evaluation of the initialization expression when initializing an object of unsigned narrow character type, that object is initialized to an indeterminate value.

- (12.4) — If an indeterminate value of unsigned narrow character type or `std::byte` type is produced by the evaluation of the initialization expression when initializing an object of `std::byte` type, that object is initialized to an indeterminate value.

[*Example*:

```
int f(bool b) {
    unsigned char c;
    unsigned char d = c;           // OK, d has an indeterminate value
    int e = d;                   // undefined behavior
    return b ? d : 0;            // undefined behavior if b is true
}
```

— end example]

- <sup>13</sup> An initializer for a static member is in the scope of the member’s class. [*Example*:

```
int a;

struct X {
    static int a;
    static int b;
};

int X::a = 1;
int X::b = a;           // X::b = X::a
```

— end example]

- <sup>14</sup> If the entity being initialized does not have class type, the *expression-list* in a parenthesized initializer shall be a single expression.

- <sup>15</sup> The initialization that occurs in the = form of a *brace-or-equal-initializer* or *condition* (??), as well as in argument passing, function return, throwing an exception (??), handling an exception (??), and aggregate member initialization (??), is called *copy-initialization*. [Note: Copy-initialization may invoke a move (??). — end note]

- <sup>16</sup> The initialization that occurs in the forms

```
T x(a);
T x{a};
```

as well as in `new` expressions (??), `static_cast` expressions (??), functional notation type conversions (??), *mem-initializers* (??), and the *braced-init-list* form of a *condition* is called *direct-initialization*.

- <sup>17</sup> The semantics of initializers are as follows. The *destination type* is the type of the object or reference being initialized and the *source type* is the type of the initializer expression. If the initializer is not a single (possibly parenthesized) expression, the source type is not defined.

- (17.1) — If the initializer is a (non-parenthesized) *braced-init-list* or is = *braced-init-list*, the object or reference is list-initialized (??).
- (17.2) — If the destination type is a reference type, see ??.
- (17.3) — If the destination type is an array of characters, an array of `char16_t`, an array of `char32_t`, or an array of `wchar_t`, and the initializer is a string literal, see ??.
- (17.4) — If the initializer is (), the object is value-initialized.

- (17.5) — Otherwise, if the destination type is an array, the program is ill-formed.
- (17.6) — If the destination type is a (possibly cv-qualified) class type:
  - (17.6.1) — If the initializer expression is a prvalue and the cv-unqualified version of the source type is the same class as the class of the destination, the initializer expression is used to initialize the destination object. [Example: `T x = T(T(T()));` calls the `T` default constructor to initialize `x`. —end example]
  - (17.6.2) — Otherwise, if the initialization is direct-initialization, or if it is copy-initialization where the cv-unqualified version of the source type is the same class as, or a derived class of, the class of the destination, constructors are considered. The applicable constructors are enumerated (??), and the best one is chosen through overload resolution (??). The constructor so selected is called to initialize the object, with the initializer expression or *expression-list* as its argument(s). If no constructor applies, or the overload resolution is ambiguous, the initialization is ill-formed.
  - (17.6.3) — Otherwise (i.e., for the remaining copy-initialization cases), user-defined conversion sequences that can convert from the source type to the destination type or (when a conversion function is used) to a derived class thereof are enumerated as described in ??, and the best one is chosen through overload resolution (??). If the conversion cannot be done or is ambiguous, the initialization is ill-formed. The function selected is called with the initializer expression as its argument; if the function is a constructor, the call is a prvalue of the cv-unqualified version of the destination type whose result object is initialized by the constructor. The call is used to direct-initialize, according to the rules above, the object that is the destination of the copy-initialization.
- (17.7) — Otherwise, if the source type is a (possibly cv-qualified) class type, conversion functions are considered. The applicable conversion functions are enumerated (??), and the best one is chosen through overload resolution (??). The user-defined conversion so selected is called to convert the initializer expression into the object being initialized. If the conversion cannot be done or is ambiguous, the initialization is ill-formed.
- (17.8) — Otherwise, the initial value of the object being initialized is the (possibly converted) value of the initializer expression. Standard conversions (??) will be used, if necessary, to convert the initializer expression to the cv-unqualified version of the destination type; no user-defined conversions are considered. If the conversion cannot be done, the initialization is ill-formed. When initializing a bit-field with a value that it cannot represent, the resulting value of the bit-field is implementation-defined. [Note: An expression of type “`cv1 T`” can initialize an object of type “`cv2 T`” independently of the cv-qualifiers `cv1` and `cv2`.

```
int a;
const int b = a;
int c = b;
```

— end note]

- <sup>18</sup> An *initializer-clause* followed by an ellipsis is a pack expansion (??).
- <sup>19</sup> If the initializer is a parenthesized *expression-list*, the expressions are evaluated in the order specified for function calls (??).
- <sup>20</sup> The same *identifier* shall not appear in multiple *designators* of a *designated-initializer-list*.
- <sup>21</sup> An object whose initialization has completed is deemed to be constructed, even if no constructor of the object’s class is invoked for the initialization. [Note: Such an object might have been value-initialized or initialized by aggregate initialization (??) or by an inherited constructor (??). —end note]

- <sup>22</sup> A declaration that specifies the initialization of a variable, whether from an explicit initializer or by default-initialization, is called the *initializing declaration* of that variable. [ *Note:* In most cases this is the defining declaration (?) of the variable, but the initializing declaration of a non-inline static data member (?) might be the declaration within the class definition and not the definition at namespace scope. — *end note* ]

### 11.6.1 Aggregates

[dcl.init.aggr]

- <sup>1</sup> An *aggregate* is an array or a class (?) with

- (1.1) — no user-provided, *explicit*, or inherited constructors (?),
- (1.2) — no private or protected non-static data members (?),
- (1.3) — no virtual functions (?), and
- (1.4) — no virtual, private, or protected base classes (?).

[ *Note:* Aggregate initialization does not allow accessing protected and private base class' members or constructors. — *end note* ]

- <sup>2</sup> The *elements* of an aggregate are:

- (2.1) — for an array, the array elements in increasing subscript order, or
- (2.2) — for a class, the direct base classes in declaration order, followed by the direct non-static data members (?) that are not members of an anonymous union, in declaration order.

- <sup>3</sup> When an aggregate is initialized by an initializer list as specified in ??, the elements of the initializer list are taken as initializers for the elements of the aggregate. The *explicitly initialized elements* of the aggregate are determined as follows:

- (3.1) — If the initializer list is a *designated-initializer-list*, the aggregate shall be of class type, the *identifier* in each *designator* shall name a direct non-static data member of the class, and the explicitly initialized elements of the aggregate are the elements that are, or contain, those members.
- (3.2) — If the initializer list is an *initializer-list*, the explicitly initialized elements of the aggregate are the first *n* elements of the aggregate, where *n* is the number of elements in the initializer list.
- (3.3) — Otherwise, the initializer list must be {}, and there are no explicitly initialized elements.

- <sup>4</sup> For each explicitly initialized element:

- (4.1) — If the element is an anonymous union object and the initializer list is a *designated-initializer-list*, the anonymous union object is initialized by the *designated-initializer-list* { *D* }, where *D* is the *designated-initializer-clause* naming a member of the anonymous union object. There shall be only one such *designated-initializer-clause*.
- (4.2) — Otherwise, the element is copy-initialized from the corresponding *initializer-clause* or the *brace-or-equal-initializer* of the corresponding *designated-initializer-clause*. If that initializer is of the form *assignment-expression* or = *assignment-expression* and a narrowing conversion (?) is required to convert the expression, the program is ill-formed. [ *Note:* If an initializer is itself an initializer list, the element is list-initialized, which will result in a recursive application of the rules in this subclause if the element is an aggregate. — *end note* ]

[ *Example:*

```
struct A {
    int x;
```

```

struct B {
    int i;
    int j;
} b;
} a = { 1, { 2, 3 } };

initializes a.x with 1, a.b.i with 2, a.b.j with 3.

struct base1 { int b1, b2 = 42; };
struct base2 {
    base2() {
        b3 = 42;
    }
    int b3;
};
struct derived : base1, base2 {
    int d;
};

derived d1{{1, 2}, {}, 4};
derived d2{{}, {}, 4};

```

initializes d1.b1 with 1, d1.b2 with 2, d1.b3 with 42, d1.d with 4, and d2.b1 with 0, d2.b2 with 42, d2.b3 with 42, d2.d with 4. — *end example*]

- 5 For a non-union aggregate, each element that is not an explicitly initialized element is initialized as follows:
  - (5.1) — If the element has a default member initializer (??), the element is initialized from that initializer.
  - (5.2) — Otherwise, if the element is not a reference, the element is copy-initialized from an empty initializer list (??).
  - (5.3) — Otherwise, the program is ill-formed.

If the aggregate is a union and the initializer list is empty, then

- (5.4) — if any variant member has a default member initializer, that member is initialized from its default member initializer;
- (5.5) — otherwise, the first member of the union (if any) is copy-initialized from an empty initializer list.

[*Example*:

```

struct S { int a; const char* b; int c; int d = b[a]; };
S ss = { 1, "asdf" };

```

initializes ss.a with 1, ss.b with "asdf", ss.c with the value of an expression of the form **int{}** (that is, 0), and ss.d with the value of ss.b[ss.a] (that is, 's'), and in

```

struct X { int i, j, k = 42; };
X a[] = { 1, 2, 3, 4, 5, 6 };
X b[2] = { { 1, 2, 3 }, { 4, 5, 6 } };

```

a and b have the same value

```

struct A {
    string a;
    int b = 42;

```

```
    int c = -1;
}
```

`A{.c=21}` has the following steps:

- (5.6) — Initialize `a` with `{}`
  - (5.7) — Initialize `b` with `= 42`
  - (5.8) — Initialize `c` with `= 21`
- end example ]

- 6 The initializations of the elements of the aggregate are evaluated in the element order. That is, all value computations and side effects associated with a given element are sequenced before those of any element that follows it in order.
- 7 An aggregate that is a class can also be initialized with a single expression not enclosed in braces, as described in ??.
- 8 An array of unknown bound initialized with a brace-enclosed *initializer-list* containing `n` *initializer-clauses*, where `n` shall be greater than zero, is defined as having `n` elements (??). [Example:

```
int x[] = { 1, 3, 5 };
```

declares and initializes `x` as a one-dimensional array that has three elements since no size was specified and there are three initializers. — end example ] An empty initializer list `{}` shall not be used as the *initializer-clause* for an array of unknown bound.<sup>107</sup> [Note: A default member initializer does not determine the bound for a member array of unknown bound. Since the default member initializer is ignored if a suitable *mem-initializer* is present (??), the default member initializer is not considered to initialize the array of unknown bound. [Example:

```
struct S {
    int y[] = { 0 };           // error: non-static data member of incomplete type
};

— end example ] — end note ]
```

- 9 [Note: Static data members, non-static data members of anonymous union members, and unnamed bit-fields are not considered elements of the aggregate. [Example:

```
struct A {
    int i;
    static int s;
    int j;
    int :17;
    int k;
} a = { 1, 2, 3 };
```

Here, the second initializer 2 initializes `a.j` and not the static data member `A::s`, and the third initializer 3 initializes `a.k` and not the unnamed bit-field before it. — end example ] — end note ]

- 10 An *initializer-list* is ill-formed if the number of *initializer-clauses* exceeds the number of elements of the aggregate. [Example:

```
char cv[4] = { 'a', 's', 'd', 'f', 0 };      // error
```

is ill-formed. — end example ]

---

<sup>107</sup> The syntax provides for empty *initializer-lists*, but nonetheless C++ does not have zero length arrays.

- <sup>11</sup> If a reference member is initialized from its default member initializer and a potentially-evaluated subexpression thereof is an aggregate initialization that would use that default member initializer, the program is ill-formed. [Example:

```
struct A;
extern A a;
struct A {
    const A& a1 { A{a,a} };      // OK
    const A& a2 { A{} };        // error
};
A a{a,a};                         // OK

— end example]
```

- <sup>12</sup> If an aggregate class C contains a subaggregate element e with no elements, the *initializer-clause* for e shall not be omitted from an *initializer-list* for an object of type C unless the *initializer-clauses* for all elements of C following e are also omitted. [Example:

```
struct S { } s;
struct A {
    S s1;
    int i1;
    S s2;
    int i2;
    S s3;
    int i3;
} a = {
    {},           // Required initialization
    0,
    s,            // Required initialization
    0
};                      // Initialization not required for A::s3 because A::i3 is also not initialized

— end example]
```

- <sup>13</sup> When initializing a multi-dimensional array, the *initializer-clauses* initialize the elements with the last (rightmost) index of the array varying the fastest (??). [Example:

```
int x[2][2] = { 3, 1, 4, 2 };
```

initializes x[0][0] to 3, x[0][1] to 1, x[1][0] to 4, and x[1][1] to 2. On the other hand,

```
float y[4][3] = {
    { 1 }, { 2 }, { 3 }, { 4 }
};
```

initializes the first column of y (regarded as a two-dimensional array) and leaves the rest zero. — end example]

- <sup>14</sup> Braces can be elided in an *initializer-list* as follows. If the *initializer-list* begins with a left brace, then the succeeding comma-separated list of *initializer-clauses* initializes the elements of a subaggregate; it is erroneous for there to be more *initializer-clauses* than elements. If, however, the *initializer-list* for a subaggregate does not begin with a left brace, then only enough *initializer-clauses* from the list are taken to initialize the elements of the subaggregate; any remaining *initializer-clauses* are left to initialize the next element of the aggregate of which the current subaggregate is an element. [Example:

```
float y[4][3] = {
    { 1, 3, 5 },
    { 2, 4, 6 },
    { 3, 5, 7 },
};
```

is a completely-braced initialization: 1, 3, and 5 initialize the first row of the array `y[0]`, namely `y[0][0]`, `y[0][1]`, and `y[0][2]`. Likewise the next two lines initialize `y[1]` and `y[2]`. The initializer ends early and therefore `y[3]`'s elements are initialized as if explicitly initialized with an expression of the form `float()`, that is, are initialized with 0.0. In the following example, braces in the *initializer-list* are elided; however the *initializer-list* has the same effect as the completely-braced *initializer-list* of the above example,

```
float y[4][3] = {
    1, 3, 5, 2, 4, 6, 3, 5, 7
};
```

The initializer for `y` begins with a left brace, but the one for `y[0]` does not, therefore three elements from the list are used. Likewise the next three are taken successively for `y[1]` and `y[2]`. — *end example*

- <sup>15</sup> All implicit type conversions (??) are considered when initializing the element with an *assignment-expression*. If the *assignment-expression* can initialize an element, the element is initialized. Otherwise, if the element is itself a subaggregate, brace elision is assumed and the *assignment-expression* is considered for the initialization of the first element of the subaggregate. [ *Note*: As specified above, brace elision cannot apply to subaggregates with no elements; an *initializer-clause* for the entire subobject is required. — *end note* ]

[ *Example*:

```
struct A {
    int i;
    operator int();
};

struct B {
    A a1, a2;
    int z;
};

A a;
B b = { 4, a, a };
```

Braces are elided around the *initializer-clause* for `b.a1.i`. `b.a1.i` is initialized with 4, `b.a2` is initialized with `a`, `b.z` is initialized with whatever `a.operator int()` returns. — *end example*

- <sup>16</sup> [ *Note*: An aggregate array or an aggregate class may contain elements of a class type with a user-provided constructor (??). Initialization of these aggregate objects is described in ???. — *end note* ]
- <sup>17</sup> [ *Note*: Whether the initialization of aggregates with static storage duration is static or dynamic is specified in ??, ??, and ???. — *end note* ]
- <sup>18</sup> When a union is initialized with an initializer list, there shall not be more than one explicitly initialized element. [ *Example*:

```
union u { int a; const char* b; };
u a = { 1 };
u b = a;
u c = 1;                                // error
u d = { 0, "asdf" };                      // error
```

```

u e = { "asdf" };           // error
u f = { .b = "asdf" };
u g = { .a = 1, .b = "asdf" }; // error
— end example]

```

- 19 [Note: As described above, the braces around the *initializer-clause* for a union member can be omitted if the union is a member of another aggregate. — end note]

### 11.6.2 Character arrays

[dcl.init.string]

- 1 An array of narrow character type (??), `char16_t` array, `char32_t` array, or `wchar_t` array can be initialized by a narrow string literal, `char16_t` string literal, `char32_t` string literal, or wide string literal, respectively, or by an appropriately-typed string literal enclosed in braces (??). Successive characters of the value of the string literal initialize the elements of the array. [Example:

```
char msg[] = "Syntax error on line %s\n";
```

shows a character array whose members are initialized with a *string-literal*. Note that because '\n' is a single character and because a trailing '\0' is appended, `sizeof(msg)` is 25. — end example]

- 2 There shall not be more initializers than there are array elements. [Example:

```
char cv[4] = "asdf";           // error
```

is ill-formed since there is no space for the implied trailing '\0'. — end example]

- 3 If there are fewer initializers than there are array elements, each element not explicitly initialized shall be zero-initialized (??).

### 11.6.3 References

[dcl.init.ref]

- 1 A variable whose declared type is “reference to type T” (??) shall be initialized. [Example:

```

int g(int) noexcept;
void f() {
    int i;
    int& r = i;           // r refers to i
    r = 1;                // the value of i becomes 1
    int* p = &r;          // p points to i
    int& rr = r;          // rr refers to what r refers to, that is, to i
    int (&rg)(int) = g;    // rg refers to the function g
    rg(i);               // calls function g
    int a[3];
    int (&ra)[3] = a;     // ra refers to the array a
    ra[1] = i;            // modifies a[1]
}

```

— end example]

- 2 A reference cannot be changed to refer to another object after initialization. [Note: Assignment to a reference assigns to the object referred to by the reference (??). — end note] Argument passing (??) and function value return (??) are initializations.

- 3 The initializer can be omitted for a reference only in a parameter declaration (??), in the declaration of a function return type, in the declaration of a class member within its class definition (??), and where the `extern` specifier is explicitly used. [Example:

```
int& r1;           // error: initializer missing
```

```
extern int& r2;           // OK
— end example]
```

- 4 Given types “*cv1 T1*” and “*cv2 T2*”, “*cv1 T1*” is *reference-related* to “*cv2 T2*” if *T1* is the same type as *T2*, or *T1* is a base class of *T2*. “*cv1 T1*” is *reference-compatible* with “*cv2 T2*” if

- (4.1) — *T1* is reference-related to *T2*, or
- (4.2) — *T2* is “*noexcept* function” and *T1* is “function”, where the function types are otherwise the same,

and *cv1* is the same cv-qualification as, or greater cv-qualification than, *cv2*. In all cases where the reference-related or reference-compatible relationship of two types is used to establish the validity of a reference binding, and *T1* is a base class of *T2*, a program that necessitates such a binding is ill-formed if *T1* is an inaccessible (??) or ambiguous (??) base class of *T2*.

- 5 A reference to type “*cv1 T1*” is initialized by an expression of type “*cv2 T2*” as follows:

- (5.1) — If the reference is an lvalue reference and the initializer expression
  - (5.1.1) — is an lvalue (but is not a bit-field), and “*cv1 T1*” is reference-compatible with “*cv2 T2*”, or
  - (5.1.2) — has a class type (i.e., *T2* is a class type), where *T1* is not reference-related to *T2*, and can be converted to an lvalue of type “*cv3 T3*”, where “*cv1 T1*” is reference-compatible with “*cv3 T3*”<sup>108</sup> (this conversion is selected by enumerating the applicable conversion functions (??) and choosing the best one through overload resolution (??)),

then the reference is bound to the initializer expression lvalue in the first case and to the lvalue result of the conversion in the second case (or, in either case, to the appropriate base class subobject of the object). [Note: The usual lvalue-to-rvalue (??), array-to-pointer (??), and function-to-pointer (??) standard conversions are not needed, and therefore are suppressed, when such direct bindings to lvalues are done. — end note]

[Example:

```
double d = 2.0;
double& rd = d;           // rd refers to d
const double& rcd = d;     // rcd refers to d

struct A {};
struct B : A { operator int&(); } b;
A& ra = b;                // ra refers to A subobject in b
const A& rca = b;          // rca refers to A subobject in b
int& ir = B();             // ir refers to the result of B::operator int&

— end example]
```

- (5.2) — Otherwise, the reference shall be an lvalue reference to a non-volatile const type (i.e., *cv1* shall be *const*), or the reference shall be an rvalue reference. [Example:

```
double& rd2 = 2.0;         // error: not an lvalue and reference not const
int i = 2;
double& rd3 = i;           // error: type mismatch and reference not const

— end example]
```

- (5.2.1) — If the initializer expression

<sup>108</sup>) This requires a conversion function (??) returning a reference type.

- (5.2.1.1) — is an rvalue (but not a bit-field) or function lvalue and “*cv1 T1*” is reference-compatible with “*cv2 T2*”, or
- (5.2.1.2) — has a class type (i.e., *T2* is a class type), where *T1* is not reference-related to *T2*, and can be converted to an rvalue or function lvalue of type “*cv3 T3*”, where “*cv1 T1*” is reference-compatible with “*cv3 T3*” (see ??),

then the value of the initializer expression in the first case and the result of the conversion in the second case is called the converted initializer. If the converted initializer is a prvalue, its type *T4* is adjusted to type “*cv1 T4*” (??) and the temporary materialization conversion (??) is applied. In any case, the reference is bound to the resulting glvalue (or to an appropriate base class subobject).

[Example:

```

struct A { };
struct B : A { } b;
extern B f();
const A& rca2 = f();                                // bound to the A subobject of the B rvalue.
A&& rra = f();                                    // same as above
struct X {
    operator B();
    operator int&();
} x;
const A& r = x;                                // bound to the A subobject of the result of the conversion
int i2 = 42;
int&& rri = static_cast<int&&>(i2); // bound directly to i2
B&& rrb = x;                                    // bound directly to the result of operator B

```

— end example]

- (5.2.2) — Otherwise:
  - (5.2.2.1) — If *T1* or *T2* is a class type and *T1* is not reference-related to *T2*, user-defined conversions are considered using the rules for copy-initialization of an object of type “*cv1 T1*” by user-defined conversion (??, ??, ??); the program is ill-formed if the corresponding non-reference copy-initialization would be ill-formed. The result of the call to the conversion function, as described for the non-reference copy-initialization, is then used to direct-initialize the reference. For this direct-initialization, user-defined conversions are not considered.
  - (5.2.2.2) — Otherwise, the initializer expression is implicitly converted to a prvalue of type “*cv1 T1*”. The temporary materialization conversion is applied and the reference is bound to the result.

If *T1* is reference-related to *T2*:

- (5.2.2.3) — *cv1* shall be the same cv-qualification as, or greater cv-qualification than, *cv2*; and
- (5.2.2.4) — if the reference is an rvalue reference, the initializer expression shall not be an lvalue.

[Example:

```

struct Banana { };
struct Enigma { operator const Banana(); };
struct Alaska { operator Banana&(); };
void enigmatic() {
    typedef const Banana ConstBanana;

```

```

        Banana &&banana1 = ConstBanana(); // ill-formed
        Banana &&banana2 = Enigma();      // ill-formed
        Banana &&banana3 = Alaska();     // ill-formed
    }

    const double& rcd2 = 2;           // rcd2 refers to temporary with value 2.0
    double&& rrd = 2;                // rrd refers to temporary with value 2.0
    const volatile int cvi = 1;
    const int& r2 = cvi;             // error: cv-qualifier dropped
    struct A { operator volatile int&(); } a;
    const int& r3 = a;               // error: cv-qualifier dropped
                                    // from result of conversion function

    double d2 = 1.0;
    double&& rrd2 = d2;             // error: initializer is lvalue of related type
    struct X { operator int&(); };
    int&& rri2 = X();               // error: result of conversion function is lvalue of related type
    int i3 = 2;
    double&& rrd3 = i3;             // rrd3 refers to temporary with value 2.0

```

— end example]

In all cases except the last (i.e., implicitly converting the initializer expression to the underlying type of the reference), the reference is said to *bind directly* to the initializer expression.

<sup>6</sup> [Note: ?? describes the lifetime of temporaries bound to references. — end note]

#### 11.6.4 List-initialization

[dcl.init.list]

<sup>1</sup> *List-initialization* is initialization of an object or reference from a *braced-init-list*. Such an initializer is called an *initializer list*, and the comma-separated *initializer-clauses* of the *initializer-list* or *designated-initializer-clauses* of the *designated-initializer-list* are called the *elements* of the initializer list. An initializer list may be empty. List-initialization can occur in direct-initialization or copy-initialization contexts; list-initialization in a direct-initialization context is called *direct-list-initialization* and list-initialization in a copy-initialization context is called *copy-list-initialization*. [Note: List-initialization can be used

- (1.1) — as the initializer in a variable definition (??)
- (1.2) — as the initializer in a *new-expression* (??)
- (1.3) — in a return statement (??)
- (1.4) — as a *for-range-initializer* (??)
- (1.5) — as a function argument (??)
- (1.6) — as a subscript (??)
- (1.7) — as an argument to a constructor invocation (??, ??)
- (1.8) — as an initializer for a non-static data member (??)
- (1.9) — in a *mem-initializer* (??)
- (1.10) — on the right-hand side of an assignment (??)

[Example:

```

int a = {1};
std::complex<double> z{1,2};

```

```

new std::vector<std::string>{"once", "upon", "a", "time"}; // 4 string elements
f( {"Nicholas", "Annemarie"} ); // pass list of two elements
return { "Norah" }; // return list of one element
int* e {}; // initialization to zero / null pointer
x = double{1}; // explicitly construct a double
std::map<std::string,int> anim = { {"bear",4}, {"cassowary",2}, {"tiger",7} };
— end example] — end note]

```

- 2 A constructor is an *initializer-list constructor* if its first parameter is of type `std::initializer_list<E>` or reference to possibly cv-qualified `std::initializer_list<E>` for some type E, and either there are no other parameters or else all other parameters have default arguments (??). [Note: Initializer-list constructors are favored over other constructors in list-initialization (??). Passing an initializer list as the argument to the constructor template `template<class T> C(T)` of a class C does not create an initializer-list constructor, because an initializer list argument causes the corresponding parameter to be a non-deduced context (??). — end note] The template `std::initializer_list` is not predefined; if the header `<initializer_list>` is not included prior to a use of `std::initializer_list` — even an implicit use in which the type is not named (??) — the program is ill-formed.

- 3 List-initialization of an object or reference of type T is defined as follows:

- (3.1) — If the *braced-init-list* contains a *designated-initializer-list*, T shall be an aggregate class. The ordered *identifiers* in the *designators* of the *designated-initializer-list* shall form a subsequence of the ordered *identifiers* in the direct non-static data members of T. Aggregate initialization is performed (??). [Example:

```

struct A { int x; int y; int z; };
A a{.y = 2, .x = 1}; // error: designator order does not match declaration order
A b{.x = 1, .z = 2}; // OK, b.y initialized to 0
— end example]

```

- (3.2) — If T is an aggregate class and the initializer list has a single element of type cv U, where U is T or a class derived from T, the object is initialized from that element (by copy-initialization for copy-list-initialization, or by direct-initialization for direct-list-initialization).

- (3.3) — Otherwise, if T is a character array and the initializer list has a single element that is an appropriately-typed string literal (??), initialization is performed as described in that subclause.

- (3.4) — Otherwise, if T is an aggregate, aggregate initialization is performed (??).

[Example:

```

double ad[] = { 1, 2.0 }; // OK
int ai[] = { 1, 2.0 }; // error: narrowing

struct S2 {
    int m1;
    double m2, m3;
};
S2 s21 = { 1, 2, 3.0 }; // OK
S2 s22 { 1.0, 2, 3 }; // error: narrowing
S2 s23 { }; // OK: default to 0,0,0
— end example]

```

- (3.5) — Otherwise, if the initializer list has no elements and T is a class type with a default constructor, the object is value-initialized.
- (3.6) — Otherwise, if T is a specialization of `std::initializer_list<E>`, the object is constructed as described below.
- (3.7) — Otherwise, if T is a class type, constructors are considered. The applicable constructors are enumerated and the best one is chosen through overload resolution (??, ??). If a narrowing conversion (see below) is required to convert any of the arguments, the program is ill-formed.

[ Example:

```
struct S {
    S(std::initializer_list<double>); // #1
    S(std::initializer_list<int>); // #2
    S(); // #3
    // ...
};

S s1 = { 1.0, 2.0, 3.0 }; // invoke #1
S s2 = { 1, 2, 3 }; // invoke #2
S s3 = { }; // invoke #3
```

— end example]

[ Example:

```
struct Map {
    Map(std::initializer_list<std::pair<std::string,int>>);
};

Map ship = {{"Sophie",14}, {"Surprise",28}};
```

— end example]

[ Example:

```
struct S {
    // no initializer-list constructors
    S(int, double, double); // #1
    S(); // #2
    // ...
};

S s1 = { 1, 2, 3.0 }; // OK: invoke #1
S s2 { 1.0, 2, 3 }; // error: narrowing
S s3 { }; // OK: invoke #2
```

— end example]

- (3.8) — Otherwise, if T is an enumeration with a fixed underlying type (??), the *initializer-list* has a single element v, and the initialization is direct-list-initialization, the object is initialized with the value T(v) (??); if a narrowing conversion is required to convert v to the underlying type of T, the program is ill-formed. [ Example:

```
enum byte : unsigned char { };
byte b { 42 }; // OK
byte c = { 42 }; // error
byte d = byte{ 42 }; // OK; same value as b
byte e { -1 }; // error
```

```

struct A { byte b; };
A a1 = { { 42 } }; // error
A a2 = { byte{ 42 } }; // OK

void f(byte);
f({ 42 }); // error

enum class Handle : uint32_t { Invalid = 0 };
Handle h { 42 }; // OK

— end example]

```

- (3.9) — Otherwise, if the initializer list has a single element of type E and either T is not a reference type or its referenced type is reference-related to E, the object or reference is initialized from that element (by copy-initialization for copy-list-initialization, or by direct-initialization for direct-list-initialization); if a narrowing conversion (see below) is required to convert the element to T, the program is ill-formed.

[ Example:

```

int x1 {2}; // OK
int x2 {2.0}; // error: narrowing

```

— end example]

- (3.10) — Otherwise, if T is a reference type, a prvalue of the type referenced by T is generated. The prvalue initializes its result object by copy-list-initialization or direct-list-initialization, depending on the kind of initialization for the reference. [ Note: As usual, the binding will fail and the program is ill-formed if the reference type is an lvalue reference to a non-const type. — end note ]

[ Example:

```

struct S {
    S(std::initializer_list<double>); // #1
    S(const std::string&); // #2
    // ...
};
const S& r1 = { 1, 2, 3.0 }; // OK: invoke #1
const S& r2 { "Spinach" }; // OK: invoke #2
S& r3 = { 1, 2, 3 }; // error: initializer is not an lvalue
const int& i1 = { 1 }; // OK
const int& i2 = { 1.1 }; // error: narrowing
const int (&iar)[2] = { 1, 2 }; // OK: iar is bound to temporary array

```

— end example]

- (3.11) — Otherwise, if the initializer list has no elements, the object is value-initialized.

[ Example:

```

int** pp {}; // initialized to null pointer

```

— end example]

- (3.12) — Otherwise, the program is ill-formed.

[ Example:

```

struct A { int i; int j; };

```

```

A a1 { 1, 2 };           // aggregate initialization
A a2 { 1.2 };           // error: narrowing
struct B {
    B(std::initializer_list<int>); // creates initializer_list<int> and calls constructor
};
B b1 { 1, 2 };           // error: narrowing
B b2 { 1, 2.0 };         // error: narrowing
struct C {
    C(int i, double j);
};
C c1 = { 1, 2.2 };       // calls constructor with arguments (1, 2.2)
C c2 = { 1.1, 2 };        // error: narrowing

int j { 1 };             // initialize to 1
int k { };               // initialize to 0

— end example]

```

- <sup>4</sup> Within the *initializer-list* of a *braced-init-list*, the *initializer-clauses*, including any that result from pack expansions (??), are evaluated in the order in which they appear. That is, every value computation and side effect associated with a given *initializer-clause* is sequenced before every value computation and side effect associated with any *initializer-clause* that follows it in the comma-separated list of the *initializer-list*. [ *Note*: This evaluation ordering holds regardless of the semantics of the initialization; for example, it applies when the elements of the *initializer-list* are interpreted as arguments of a constructor call, even though ordinarily there are no sequencing constraints on the arguments of a call. — *end note* ]
- <sup>5</sup> An object of type `std::initializer_list<E>` is constructed from an initializer list as if the implementation generated and materialized (??) a prvalue of type “array of *N const E*”, where *N* is the number of elements in the initializer list. Each element of that array is copy-initialized with the corresponding element of the initializer list, and the `std::initializer_list<E>` object is constructed to refer to that array. [ *Note*: A constructor or conversion function selected for the copy shall be accessible (??) in the context of the initializer list. — *end note* ] If a narrowing conversion is required to initialize any of the elements, the program is ill-formed. [ *Example*:

```

struct X {
    X(std::initializer_list<double> v);
};

X x{ 1,2,3 };

```

The initialization will be implemented in a way roughly equivalent to this:

```

const double __a[3] = {double{1}, double{2}, double{3}};
X x(std::initializer_list<double>(__a, __a+3));

```

assuming that the implementation can construct an `initializer_list` object with a pair of pointers. — *end example* ]

- <sup>6</sup> The array has the same lifetime as any other temporary object (??), except that initializing an `initializer_list` object from the array extends the lifetime of the array exactly like binding a reference to a temporary. [ *Example*:

```

typedef std::complex<double> cmplx;
std::vector<cmplx> v1 = { 1, 2, 3 };

```

```

void f() {
    std::vector<cmplx> v2{ 1, 2, 3 };
    std::initializer_list<int> i3 = { 1, 2, 3 };
}

struct A {
    std::initializer_list<int> i4;
    A() : i4{ 1, 2, 3 } {}           // ill-formed, would create a dangling reference
};

```

For `v1` and `v2`, the `initializer_list` object is a parameter in a function call, so the array created for `{ 1, 2, 3 }` has full-expression lifetime. For `i3`, the `initializer_list` object is a variable, so the array persists for the lifetime of the variable. For `i4`, the `initializer_list` object is initialized in the constructor's *ctor-initializer* as if by binding a temporary array to a reference member, so the program is ill-formed (??). — *end example*] [Note: The implementation is free to allocate the array in read-only memory if an explicit array with the same initializer could be so allocated. — *end note*]

<sup>7</sup> A *narrowing conversion* is an implicit conversion

- (7.1) — from a floating-point type to an integer type, or
- (7.2) — from `long double` to `double` or `float`, or from `double` to `float`, except where the source is a constant expression and the actual value after conversion is within the range of values that can be represented (even if it cannot be represented exactly), or
- (7.3) — from an integer type or unscoped enumeration type to a floating-point type, except where the source is a constant expression and the actual value after conversion will fit into the target type and will produce the original value when converted back to the original type, or
- (7.4) — from an integer type or unscoped enumeration type to an integer type that cannot represent all the values of the original type, except where the source is a constant expression whose value after integral promotions will fit into the target type.

[Note: As indicated above, such conversions are not allowed at the top level in list-initializations. — *end note*] [Example:

```

int x = 999;                      // x is not a constant expression
const int y = 999;
const int z = 99;
char c1 = x;                      // OK, though it might narrow (in this case, it does narrow)
char c2{x};                       // error: might narrow
char c3{y};                       // error: narrows (assuming char is 8 bits)
char c4{z};                       // OK: no narrowing needed
unsigned char uc1 = {5};           // OK: no narrowing needed
unsigned char uc2 = {-1};          // error: narrows
unsigned int ui1 = {-1};           // error: narrows
signed int si1 =
    { (unsigned int)-1 };          // error: narrows
int ii = {2.0};                   // error: narrows
float f1 { x };                  // error: might narrow
float f2 { 7 };                  // OK: 7 can be exactly represented as a float
int f(int);
int a[] = { 2, f(2), f(2.0) };   // OK: the double-to-int conversion is not at the top level

```

— *end example* ]

## 12 Classes

[class]

- <sup>1</sup> A class is a type. Its name becomes a *class-name* (??) within its scope.

```
class-name:
    identifier
    simple-template-id
```

*Class-specifiers* and *elaborated-type-specifiers* (??) are used to make *class-names*. An object of a class consists of a (possibly empty) sequence of members and base class objects.

```
class-specifier:
    class-head { member-specificationopt }

class-head:
    class-key attribute-specifier-seqopt class-head-name class-virt-specifieropt base-clauseopt
    class-key attribute-specifier-seqopt base-clauseopt

class-head-name:
    nested-name-specifieropt class-name

class-virt-specifier:
    final

class-key:
    class
    struct
    union
```

A *class-specifier* whose *class-head* omits the *class-head-name* defines an unnamed class. [Note: An unnamed class thus can't be **final**. —end note]

- <sup>2</sup> A *class-name* is inserted into the scope in which it is declared immediately after the *class-name* is seen. The *class-name* is also inserted into the scope of the class itself; this is known as the *injected-class-name*. For purposes of access checking, the injected-class-name is treated as if it were a public member name. A *class-specifier* is commonly referred to as a class definition. A class is considered defined after the closing brace of its *class-specifier* has been seen even though its member functions are in general not yet defined. The optional *attribute-specifier-seq* appertains to the class; the attributes in the *attribute-specifier-seq* are thereafter considered attributes of the class whenever it is named.
- <sup>3</sup> If a class is marked with the *class-virt-specifier* **final** and it appears as a *class-or-decltype* in a *base-clause* (??), the program is ill-formed. Whenever a *class-key* is followed by a *class-head-name*, the *identifier* **final**, and a colon or left brace, **final** is interpreted as a *class-virt-specifier*. [Example:

```
struct A;
struct A final {};
// OK: definition of struct A,
// not value-initialization of variable final

struct X {
    struct C { constexpr operator int() { return 5; } };
    struct B final : C{}; // OK: definition of nested class B,
                        // not declaration of a bit-field member final
};
```

— end example]

- 4 Complete objects and member subobjects of class type shall have nonzero size.<sup>109</sup> [Note: Class objects can be assigned, passed as arguments to functions, and returned by functions (except objects of classes for which copying or moving has been restricted; see ??). Other plausible operators, such as equality comparison, can be defined by the user; see ??.
- end note]
- 5 A *union* is a class defined with the *class-key union*; it holds at most one data member at a time (??). [Note: Aggregates of class type are described in ??.
- end note]
- 6 A *trivially copyable class* is a class:
  - (6.1) — where each copy constructor, move constructor, copy assignment operator, and move assignment operator (??, ??) is either deleted or trivial,
  - (6.2) — that has at least one non-deleted copy constructor, move constructor, copy assignment operator, or move assignment operator, and
  - (6.3) — that has a trivial, non-deleted destructor (??).

A *trivial class* is a class that is trivially copyable and has one or more default constructors (??), all of which are either trivial or deleted and at least one of which is not deleted. [Note: In particular, a trivially copyable or trivial class does not have virtual functions or virtual base classes. — end note]

- 7 A class **S** is a *standard-layout class* if it:
  - (7.1) — has no non-static data members of type non-standard-layout class (or array of such types) or reference,
  - (7.2) — has no virtual functions (??) and no virtual base classes (??),
  - (7.3) — has the same access control (??) for all non-static data members,
  - (7.4) — has no non-standard-layout base classes,
  - (7.5) — has at most one base class subobject of any given type,
  - (7.6) — has all non-static data members and bit-fields in the class and its base classes first declared in the same class, and
  - (7.7) — has no element of the set  $M(S)$  of types (defined below) as a base class.<sup>110</sup>

$M(X)$  is defined as follows:

- (7.8) — If **X** is a non-union class type with no (possibly inherited (??)) non-static data members, the set  $M(X)$  is empty.
- (7.9) — If **X** is a non-union class type whose first non-static data member has type  $X_0$  (where said member may be an anonymous union), the set  $M(X)$  consists of  $X_0$  and the elements of  $M(X_0)$ .
- (7.10) — If **X** is a union type, the set  $M(X)$  is the union of all  $M(U_i)$  and the set containing all  $U_i$ , where each  $U_i$  is the type of the  $i$ th non-static data member of **X**.
- (7.11) — If **X** is an array type with element type  $X_e$ , the set  $M(X)$  consists of  $X_e$  and the elements of  $M(X_e)$ .
- (7.12) — If **X** is a non-class, non-array type, the set  $M(X)$  is empty.

[Note:  $M(X)$  is the set of the types of all non-base-class subobjects that are guaranteed in a standard-layout class to be at a zero offset in **X**. — end note]

<sup>109</sup>) Base class subobjects are not so constrained.

<sup>110</sup>) This ensures that two subobjects that have the same class type and that belong to the same most derived object are not allocated at the same address (??).

[*Example:*

```
struct B { int i; };           // standard-layout class
struct C : B { };            // standard-layout class
struct D : C { };            // standard-layout class
struct E : D { char : 4; };   // not a standard-layout class

struct Q {};
struct S : Q { };
struct T : Q { };
struct U : S, T { };         // not a standard-layout class
```

— *end example*]

- <sup>8</sup> A *standard-layout struct* is a standard-layout class defined with the *class-key struct* or the *class-key class*. A *standard-layout union* is a standard-layout class defined with the *class-key union*.
- <sup>9</sup> [*Note:* Standard-layout classes are useful for communicating with code written in other programming languages. Their layout is specified in ??.— *end note*]
- <sup>10</sup> [*Example:*

```
struct N {                  // neither trivial nor standard-layout
    int i;
    int j;
    virtual ~N();
};

struct T {                  // trivial but not standard-layout
    int i;
private:
    int j;
};

struct SL {                 // standard-layout but not trivial
    int i;
    int j;
    ~SL();
};

struct POD {                // both trivial and standard-layout
    int i;
    int j;
};

— end example]
```

- <sup>11</sup> If a *class-head-name* contains a *nested-name-specifier*, the *class-specifier* shall refer to a class that was previously declared directly in the class or namespace to which the *nested-name-specifier* refers, or in an element of the inline namespace set (??) of that namespace (i.e., not merely inherited or introduced by a *using-declaration*), and the *class-specifier* shall appear in a namespace enclosing the previous declaration. In such cases, the *nested-name-specifier* of the *class-head-name* of the definition shall not begin with a *decltype-specifier*.

## 12.1 Class names

[**class.name**]

- <sup>1</sup> A class definition introduces a new type. [ *Example*:

```
struct X { int a; };
struct Y { int a; };
X a1;
Y a2;
int a3;
```

declares three variables of three different types. This implies that

```
a1 = a2;           // error: Y assigned to X
a1 = a3;           // error: int assigned to X
```

are type mismatches, and that

```
int f(X);
int f(Y);
```

declare an overloaded (??) function **f()** and not simply a single function **f()** twice. For the same reason,

```
struct S { int a; };
struct S { int a; };           // error, double definition
```

is ill-formed because it defines **S** twice. — *end example*]

- <sup>2</sup> A class declaration introduces the class name into the scope where it is declared and hides any class, variable, function, or other declaration of that name in an enclosing scope (??). If a class name is declared in a scope where a variable, function, or enumerator of the same name is also declared, then when both declarations are in scope, the class can be referred to only using an *elaborated-type-specifier* (??). [ *Example*:

```
struct stat {
    // ...
};

stat gstat;           // use plain stat to define variable

int stat(struct stat*);      // redeclare stat as function

void f() {
    struct stat* ps;          // struct prefix needed to name struct stat
    stat(ps);                // call stat()
}
```

— *end example*] A *declaration* consisting solely of *class-key identifier*; is either a redeclaration of the name in the current scope or a forward declaration of the identifier as a class name. It introduces the class name into the current scope. [ *Example*:

```
struct s { int a; };

void g() {
    struct s;                  // hide global struct s with a block-scope declaration
    s* p;                      // refer to local struct s
    struct s { char* p; };     // define local struct s
    struct s;                  // redeclaration, has no effect
}
```

— end example] [ Note: Such declarations allow definition of classes that refer to each other. [ Example:

```
class Vector;

class Matrix {
    // ...
    friend Vector operator*(const Matrix&, const Vector&);
};

class Vector {
    // ...
    friend Vector operator*(const Matrix&, const Vector&);
};
```

Declaration of friends is described in ??, operator functions in ??.

- end example] — end note]
- <sup>3</sup> [ Note: An *elaborated-type-specifier* (??) can also be used as a *type-specifier* as part of a declaration. It differs from a class declaration in that if a class of the elaborated name is in scope the elaborated name will refer to it. — end note] [ Example:

```
struct s { int a; };

void g(int s) {
    struct s* p = new struct s;    // global s
    p->a = s;                  // parameter s
}
```

— end example]

- <sup>4</sup> [ Note: The declaration of a class name takes effect immediately after the *identifier* is seen in the class definition or *elaborated-type-specifier*. For example,

```
class A * A;
```

first specifies A to be the name of a class and then redefines it as the name of a pointer to an object of that class. This means that the elaborated form **class A** must be used to refer to the class. Such artistry with names can be confusing and is best avoided. — end note]

- <sup>5</sup> A *typedef-name* (??) that names a class type, or a cv-qualified version thereof, is also a *class-name*. If a *typedef-name* that names a cv-qualified class type is used where a *class-name* is required, the cv-qualifiers are ignored. A *typedef-name* shall not be used as the *identifier* in a *class-head*.

## 12.2 Class members

[class.mem]

*member-specification*:

```
member-declaration member-specificationopt
access-specifier : member-specificationopt
```

```

member-declaration:
    attribute-specifier-seqopt decl-specifier-seqopt member-declarator-listopt ;
    function-definition
    using-declaration
    static_assert-declaration
    template-declaration
    deduction-guide
    alias-declaration
    empty-declaration

member-declarator-list:
    member-declarator
    member-declarator-list , member-declarator

member-declarator:
    declarator virt-specifier-seqopt pure-specifieropt
    declarator requires-clause
    declarator brace-or-equal-initializeropt
    identifieropt attribute-specifier-seqopt : constant-expression brace-or-equal-initializeropt

virt-specifier-seq:
    virt-specifier
    virt-specifier-seq virt-specifier

virt-specifier:
    override
    final

pure-specifier:
    = 0

```

<sup>1</sup> The *member-specification* in a class definition declares the full set of members of the class; no member can be added elsewhere. A *direct member* of a class X is a member of X that was first declared within the *member-specification* of X, including anonymous union objects (??) and direct members thereof. Members of a class are data members, member functions (??), nested types, enumerators, and member templates (??) and specializations thereof. [ *Note:* A specialization of a static data member template is a static data member. A specialization of a member function template is a member function. A specialization of a member class template is a nested class. — *end note* ]

<sup>2</sup> A *member-declaration* does not declare new members of the class if it is

- (2.1) — a friend declaration (??),
- (2.2) — a *static\_assert-declaration*,
- (2.3) — a *using-declaration* (??), or
- (2.4) — an *empty-declaration*.

For any other *member-declaration*, each declared entity that is not an unnamed bit-field (??) is a member of the class, and each such *member-declaration* shall either declare at least one member name of the class or declare at least one unnamed bit-field.

<sup>3</sup> A *data member* is a non-function member introduced by a *member-declarator*. A *member function* is a member that is a function. Nested types are classes (??, ??) and enumerations (??) declared in the class and arbitrary types declared as members by use of a *typedef declaration* (??) or *alias-declaration*. The enumerators of an unscoped enumeration (??) defined in the class are members of the class.

- <sup>4</sup> A data member or member function may be declared **static** in its *member-declaration*, in which case it is a *static member* (see ??) (a *static data member* ?? or *static member function* ??, respectively) of the class. Any other data member or member function is a *non-static member* (a *non-static data member* or *non-static member function* ??, respectively). [ *Note*: A non-static data member of non-reference type is a member subobject of a class object ??]. — *end note* ]
- <sup>5</sup> A member shall not be declared twice in the *member-specification*, except that
- (5.1) — a nested class or member class template can be declared and then later defined, and
  - (5.2) — an enumeration can be introduced with an *opaque-enum-declaration* and later redeclared with an *enum-specifier*.
- [ *Note*: A single name can denote several member functions provided their types are sufficiently different ??]. — *end note* ]
- <sup>6</sup> A class is considered a completely-defined object type ?? (or complete type) at the closing } of the *class-specifier*. Within the class *member-specification*, the class is regarded as complete within function bodies, default arguments, *noexcept-specifiers*, and default member initializers (including such things in nested classes). Otherwise it is regarded as incomplete within its own class *member-specification*.
- <sup>7</sup> In a *member-declarator*, an = immediately following the *declarator* is interpreted as introducing a *pure-specifier* if the *declarator-id* has function type, otherwise it is interpreted as introducing a *brace-or-equal-initializer*. [ *Example*:

```
struct S {
    using T = void();
    T * p = 0;           // OK: brace-or-equal-initializer
    virtual T f = 0;    // OK: pure-specifier
};

— end example ]
```

- <sup>8</sup> In a *member-declarator* for a bit-field, the *constant-expression* is parsed as the longest sequence of tokens that could syntactically form a *constant-expression*. [ *Example*:

```
int a;
const int b = 0;
struct S {
    int x1 : 8 = 42;          // OK, "= 42" is brace-or-equal-initializer
    int x2 : 8 { 42 };        // OK, "{ 42 }" is brace-or-equal-initializer
    int y1 : true ? 8 : a = 42; // OK, brace-or-equal-initializer is absent
    int y2 : true ? 8 : b = 42; // error: cannot assign to const int
    int y3 : (true ? 8 : b) = 42; // OK, "= 42" is brace-or-equal-initializer
    int z : 1 || new int { 0 }; // OK, brace-or-equal-initializer is absent
};

— end example ]
```

- <sup>9</sup> A *brace-or-equal-initializer* shall appear only in the declaration of a data member. (For static data members, see ??; for non-static data members, see ?? and ??). A *brace-or-equal-initializer* for a non-static data member specifies a *default member initializer* for the member, and shall not directly or indirectly cause the implicit definition of a defaulted default constructor for the enclosing class or the exception specification of that constructor.

- <sup>10</sup> A member shall not be declared with the `extern storage-class-specifier`. Within a class definition, a member shall not be declared with the `thread_local storage-class-specifier` unless also declared `static`.
- <sup>11</sup> The *decl-specifier-seq* may be omitted in constructor, destructor, and conversion function declarations only; when declaring another kind of member the *decl-specifier-seq* shall contain a *type-specifier* that is not a *cv-qualifier*. The *member-declarator-list* can be omitted only after a *class-specifier* or an *enum-specifier* or in a friend declaration (??). A *pure-specifier* shall be used only in the declaration of a virtual function (??) that is not a friend declaration.
- <sup>12</sup> The optional *attribute-specifier-seq* in a *member-declaration* appertains to each of the entities declared by the *member-declarators*; it shall not appear if the optional *member-declarator-list* is omitted.
- <sup>13</sup> A *virt-specifier-seq* shall contain at most one of each *virt-specifier*. A *virt-specifier-seq* shall appear only in the declaration of a virtual member function (??).
- <sup>14</sup> Non-static data members shall not have incomplete types. In particular, a class `C` shall not contain a non-static member of class `C`, but it can contain a pointer or reference to an object of class `C`.
- <sup>15</sup> [ *Note*: See ?? for restrictions on the use of non-static data members and non-static member functions. — *end note* ]
- <sup>16</sup> [ *Note*: The type of a non-static member function is an ordinary function type, and the type of a non-static data member is an ordinary object type. There are no special member function types or data member types. — *end note* ]
- <sup>17</sup> [ *Example*: A simple example of a class definition is

```
struct tnode {
    char tword[20];
    int count;
    tnode* left;
    tnode* right;
};
```

which contains an array of twenty characters, an integer, and two pointers to objects of the same type. Once this definition has been given, the declaration

```
tnode s, *sp;
```

declares `s` to be a `tnode` and `sp` to be a pointer to a `tnode`. With these declarations, `sp->count` refers to the `count` member of the object to which `sp` points; `s.left` refers to the `left` subtree pointer of the object `s`; and `s.right->tword[0]` refers to the initial character of the `tword` member of the `right` subtree of `s`. — *end example* ]

- <sup>18</sup> Non-static data members of a (non-union) class with the same access control (??) are allocated so that later members have higher addresses within a class object. The order of allocation of non-static data members with different access control is unspecified (??). Implementation alignment requirements might cause two adjacent members not to be allocated immediately after each other; so might requirements for space for managing virtual functions (??) and virtual base classes (??).
- <sup>19</sup> If `T` is the name of a class, then each of the following shall have a name different from `T`:
- (19.1) — every static data member of class `T`;
  - (19.2) — every member function of class `T` [ *Note*: This restriction does not apply to constructors, which do not have names (??) — *end note* ] ;
  - (19.3) — every member of class `T` that is itself a type;

- (19.4) — every member template of class T;
- (19.5) — every enumerator of every member of class T that is an unscoped enumerated type; and
- (19.6) — every member of every anonymous union that is a member of class T.
- 20 In addition, if class T has a user-declared constructor (??), every non-static data member of class T shall have a name different from T.
- 21 The *common initial sequence* of two standard-layout struct (??) types is the longest sequence of non-static data members and bit-fields in declaration order, starting with the first such entity in each of the structs, such that corresponding entities have layout-compatible types and either neither entity is a bit-field or both are bit-fields with the same width. [Example:
- ```
struct A { int a; char b; };
struct B { const int b1; volatile char b2; };
struct C { int c; unsigned : 0; char b; };
struct D { int d; char b : 4; };
struct E { unsigned int e; char b; };
```
- The common initial sequence of A and B comprises all members of either class. The common initial sequence of A and C and of A and D comprises the first member in each case. The common initial sequence of A and E is empty. —end example]
- 22 Two standard-layout struct (??) types are *layout-compatible classes* if their common initial sequence comprises all members and bit-fields of both classes (??).
- 23 Two standard-layout unions are layout-compatible if they have the same number of non-static data members and corresponding non-static data members (in any order) have layout-compatible types (??).
- 24 In a standard-layout union with an active member (??) of struct type T1, it is permitted to read a non-static data member m of another union member of struct type T2 provided m is part of the common initial sequence of T1 and T2; the behavior is as if the corresponding member of T1 were nominated. [Example:
- ```
struct T1 { int a, b; };
struct T2 { int c; double d; };
union U { T1 t1; T2 t2; };
int f() {
    U u = { { 1, 2 } }; // active member is t1
    return u.t2.c; // OK, as if u.t1.a were nominated
}
```

—end example] [Note: Reading a volatile object through a non-volatile glvalue has undefined behavior (??). —end note]

- 25 If a standard-layout class object has any non-static data members, its address is the same as the address of its first non-static data member. Otherwise, its address is the same as the address of its first base class subobject (if any). [Note: There might therefore be unnamed padding within a standard-layout struct object, but not at its beginning, as necessary to achieve appropriate alignment. —end note] [Note: The object and its first subobject are pointer-interconvertible (??, ??). —end note]

### 12.2.1 Member functions

[class.mfct]

- <sup>1</sup> A member function may be defined (??) in its class definition, in which case it is an *inline* member function (??), or it may be defined outside of its class definition if it has already been declared but not defined in its class definition. A member function definition that appears outside of the class definition

shall appear in a namespace scope enclosing the class definition. Except for member function definitions that appear outside of a class definition, and except for explicit specializations of member functions of class templates and member function templates (??) appearing outside of the class definition, a member function shall not be redeclared.

- 2 An inline member function (whether static or non-static) may also be defined outside of its class definition provided either its declaration in the class definition or its definition outside of the class definition declares the function as `inline` or `constexpr`. [Note: Member functions of a class in namespace scope have the linkage of that class. Member functions of a local class (??) have no linkage. See ?? . —end note]
- 3 [Note: There can be at most one definition of a non-inline member function in a program. There may be more than one inline member function definition in a program. See ?? and ?? . —end note]
- 4 If the definition of a member function is lexically outside its class definition, the member function name shall be qualified by its class name using the `::` operator. [Note: A name used in a member function definition (that is, in the *parameter-declaration-clause* including the default arguments (??) or in the member function body) is looked up as described in ?? . —end note] [Example:

```
struct X {
    typedef int T;
    static T count;
    void f(T);
};

void X::f(T t = count) { }
```

The member function `f` of class `X` is defined in global scope; the notation `X::f` specifies that the function `f` is a member of class `X` and in the scope of class `X`. In the function definition, the parameter type `T` refers to the `typedef` member `T` declared in class `X` and the default argument `count` refers to the static data member `count` declared in class `X`. —end example]

- 5 [Note: A `static` local variable or local type in a member function always refers to the same entity, whether or not the member function is inline. —end note]
- 6 Previously declared member functions may be mentioned in friend declarations.
- 7 Member functions of a local class shall be defined inline in their class definition, if they are defined at all.
- 8 [Note: A member function can be declared (but not defined) using a `typedef` for a function type. The resulting member function has exactly the same type as it would have if the function declarator were provided explicitly, see ?? . For example,

```
typedef void fv();
typedef void fvc() const;
struct S {
    fv memfunc1;      // equivalent to: void memfunc1();
    void memfunc2();
    fvc memfunc3;    // equivalent to: void memfunc3() const;
};
fv S::* pmfv1 = &S::memfunc1;
fv S::* pmfv2 = &S::memfunc2;
fvc S::* pmfv3 = &S::memfunc3;
```

Also see ?? . —end note]

### 12.2.2 Non-static member functions

[class.mfct.non-static]

- 1 A non-static member function may be called for an object of its class type, or for an object of a class derived (??) from its class type, using the class member access syntax (??, ??). A non-static member function may also be called directly using the function call syntax (??, ??) from within the body of a member function of its class or of a class derived from its class.
- 2 If a non-static member function of a class X is called for an object that is not of type X, or of a type derived from X, the behavior is undefined.
- 3 When an *id-expression* (??) that is not part of a class member access syntax (??) and not used to form a pointer to member (??) is used in a member of class X in a context where **this** can be used (??), if name lookup (??) resolves the name in the *id-expression* to a non-static non-type member of some class C, and if either the *id-expression* is potentially evaluated or C is X or a base class of X, the *id-expression* is transformed into a class member access expression (??) using (**\*this**) (??) as the *postfix-expression* to the left of the . operator. [Note: If C is not X or a base class of X, the class member access expression is ill-formed. —end note] Similarly during name lookup, when an *unqualified-id* (??) used in the definition of a member function for class X resolves to a static member, an enumerator or a nested type of class X or of a base class of X, the *unqualified-id* is transformed into a *qualified-id* (??) in which the *nested-name-specifier* names the class of the member function. These transformations do not apply in the template definition context (??). [Example:

```

struct tnode {
    char tword[20];
    int count;
    tnode* left;
    tnode* right;
    void set(const char*, tnode* l, tnode* r);
};

void tnode::set(const char* w, tnode* l, tnode* r) {
    count = strlen(w)+1;
    if (sizeof(tword)<=count)
        perror("tnode string too long");
    strcpy(tword,w);
    left = l;
    right = r;
}

void f(tnode n1, tnode n2) {
    n1.set("abc",&n2,0);
    n2.set("def",0,0);
}

```

In the body of the member function **tnode::set**, the member names **tword**, **count**, **left**, and **right** refer to members of the object for which the function is called. Thus, in the call **n1.set("abc",&n2,0)**, **tword** refers to **n1.tword**, and in the call **n2.set("def",0,0)**, it refers to **n2.tword**. The functions **strlen**, **perror**, and **strcpy** are not members of the class **tnode** and should be declared elsewhere.<sup>111</sup> —end example]

- 4 A non-static member function may be declared **const**, **volatile**, or **const volatile**. These *cv-qualifiers* affect the type of the **this** pointer (??). They also affect the function type (??) of the member function;

<sup>111</sup> See, for example, <cstring> (??).

a member function declared `const` is a *const member function*, a member function declared `volatile` is a *volatile member function* and a member function declared `const volatile` is a *const volatile member function*. [Example:

```
struct X {
    void g() const;
    void h() const volatile;
};
```

`X::g` is a *const member function* and `X::h` is a *const volatile member function*. — end example]

<sup>5</sup> A non-static member function may be declared with a *ref-qualifier* (??); see ??.

<sup>6</sup> A non-static member function may be declared *virtual* (??) or *pure virtual* (??).

### 12.2.2.1 The `this` pointer

[`class.this`]

<sup>1</sup> In the body of a non-static (??) member function, the keyword `this` is a prvalue expression whose value is the address of the object for which the function is called. The type of `this` in a member function of a class `X` is `X*`. If the member function is declared `const`, the type of `this` is `const X*`, if the member function is declared `volatile`, the type of `this` is `volatile X*`, and if the member function is declared `const volatile`, the type of `this` is `const volatile X*`. [Note: Thus in a *const member function*, the object for which the function is called is accessed through a *const access path*. — end note] [Example:

```
struct s {
    int a;
    int f() const;
    int g() { return a++; }
    int h() const { return a++; } // error
};

int s::f() const { return a; }
```

The `a++` in the body of `s::h` is ill-formed because it tries to modify (a part of) the object for which `s::h()` is called. This is not allowed in a *const member function* because `this` is a pointer to `const`; that is, `*this` has `const` type. — end example]

<sup>2</sup> Similarly, `volatile` semantics (??) apply in *volatile member functions* when accessing the object and its non-static data members.

<sup>3</sup> A cv-qualified member function can be called on an object-expression (??) only if the object-expression is as cv-qualified or less-cv-qualified than the member function. [Example:

```
void k(s& x, const s& y) {
    x.f();
    x.g();
    y.f();
    y.g(); // error
}
```

The call `y.g()` is ill-formed because `y` is `const` and `s::g()` is a non-`const` member function, that is, `s::g()` is less-qualified than the object-expression `y`. — end example]

<sup>4</sup> Constructors (??) and destructors (??) shall not be declared `const`, `volatile` or `const volatile`. [Note: However, these functions can be invoked to create and destroy objects with cv-qualified types, see ?? and ??.— end note]

### 12.2.3 Static members

[**class.static**]

- <sup>1</sup> A static member **s** of class **X** may be referred to using the *qualified-id* expression **X::s**; it is not necessary to use the class member access syntax (??) to refer to a static member. A static member may be referred to using the class member access syntax, in which case the object expression is evaluated. [*Example*:

```
struct process {
    static void reschedule();
};

process& g();

void f() {
    process::reschedule();           // OK: no object necessary
    g().reschedule();              // g() is called
}
```

— *end example*]

- <sup>2</sup> A static member may be referred to directly in the scope of its class or in the scope of a class derived (??) from its class; in this case, the static member is referred to as if a *qualified-id* expression was used, with the *nested-name-specifier* of the *qualified-id* naming the class scope from which the static member is referenced. [*Example*:

```
int g();
struct X {
    static int g();
};
struct Y : X {
    static int i;
};
int Y::i = g();                  // equivalent to Y::g();

```

— *end example*]

- <sup>3</sup> If an *unqualified-id* (??) is used in the definition of a static member following the member's *declarator-id*, and name lookup (??) finds that the *unqualified-id* refers to a static member, enumerator, or nested type of the member's class (or of a base class of the member's class), the *unqualified-id* is transformed into a *qualified-id* expression in which the *nested-name-specifier* names the class scope from which the member is referenced. [*Note*: See ?? for restrictions on the use of non-static data members and non-static member functions. — *end note*]
- <sup>4</sup> Static members obey the usual class member access rules (??). When used in the declaration of a class member, the **static** specifier shall only be used in the member declarations that appear within the *member-specification* of the class definition. [*Note*: It cannot be specified in member declarations that appear in namespace scope. — *end note*]

#### 12.2.3.1 Static member functions

[**class.static.mfct**]

- <sup>1</sup> [*Note*: The rules described in ?? apply to static member functions. — *end note*]
- <sup>2</sup> [*Note*: A static member function does not have a **this** pointer (??). — *end note*] A static member function shall not be **virtual**. There shall not be a static and a non-static member function with the same name and the same parameter types (??). A static member function shall not be declared **const**, **volatile**, or **const volatile**.

### 12.2.3.2 Static data members

[**class.static.data**]

- <sup>1</sup> A static data member is not part of the subobjects of a class. If a static data member is declared `thread_local` there is one copy of the member per thread. If a static data member is not declared `thread_local` there is one copy of the data member that is shared by all the objects of the class.
- <sup>2</sup> The declaration of a non-inline static data member in its class definition is not a definition and may be of an incomplete type other than `cv void`. The definition for a static data member that is not defined inline in the class definition shall appear in a namespace scope enclosing the member's class definition. In the definition at namespace scope, the name of the static data member shall be qualified by its class name using the `::` operator. The *initializer* expression in the definition of a static data member is in the scope of its class (??).  
[*Example:*

```
class process {
    static process* run_chain;
    static process* running;
};

process* process::running = get_main();
process* process::run_chain = running;
```

The static data member `run_chain` of class `process` is defined in global scope; the notation `process::run_chain` specifies that the member `run_chain` is a member of class `process` and in the scope of class `process`. In the static data member definition, the *initializer* expression refers to the static data member `running` of class `process`. — *end example*]

[*Note:* Once the static data member has been defined, it exists even if no objects of its class have been created. [*Example:* In the example above, `run_chain` and `running` exist even if no objects of class `process` are created by the program. — *end example*] — *end note*]

- <sup>3</sup> If a non-volatile non-inline `const` static data member is of integral or enumeration type, its declaration in the class definition can specify a *brace-or-equal-initializer* in which every *initializer-clause* that is an *assignment-expression* is a constant expression (??). The member shall still be defined in a namespace scope if it is odr-used (??) in the program and the namespace scope definition shall not contain an *initializer*. An inline static data member may be defined in the class definition and may specify a *brace-or-equal-initializer*. If the member is declared with the `constexpr` specifier, it may be redeclared in namespace scope with no initializer (this usage is deprecated; see ??). Declarations of other static data members shall not specify a *brace-or-equal-initializer*.
- <sup>4</sup> [*Note:* There shall be exactly one definition of a static data member that is odr-used (??) in a program; no diagnostic is required. — *end note*] Unnamed classes and classes contained directly or indirectly within unnamed classes shall not contain static data members.
- <sup>5</sup> [*Note:* Static data members of a class in namespace scope have the linkage of that class (??). A local class cannot have static data members (??). — *end note*]
- <sup>6</sup> Static data members are initialized and destroyed exactly like non-local variables (??, ??, ??).
- <sup>7</sup> A static data member shall not be `mutable` (??).

### 12.2.4 Bit-fields

[**class.bit**]

- <sup>1</sup> A *member-declarator* of the form

*identifier<sub>opt</sub>* *attribute-specifier-seq<sub>opt</sub>* : *constant-expression brace-or-equal-initializer<sub>opt</sub>*

specifies a bit-field; its length is set off from the bit-field name by a colon. The optional *attribute-specifier-seq* appertains to the entity being declared. The bit-field attribute is not part of the type of the class member. The *constant-expression* shall be an integral constant expression with a value greater than or equal to zero. The value of the integral constant expression may be larger than the number of bits in the object representation (??) of the bit-field's type; in such cases the extra bits are padding bits (??). Allocation of bit-fields within a class object is implementation-defined. Alignment of bit-fields is implementation-defined. Bit-fields are packed into some addressable allocation unit. [Note: Bit-fields straddle allocation units on some machines and not on others. Bit-fields are assigned right-to-left on some machines, left-to-right on others. —end note]

- 2 A declaration for a bit-field that omits the *identifier* declares an *unnamed bit-field*. Unnamed bit-fields are not members and cannot be initialized. [Note: An unnamed bit-field is useful for padding to conform to externally-imposed layouts. —end note] As a special case, an unnamed bit-field with a width of zero specifies alignment of the next bit-field at an allocation unit boundary. Only when declaring an unnamed bit-field may the value of the *constant-expression* be equal to zero.
- 3 A bit-field shall not be a static member. A bit-field shall have integral or enumeration type (??). A **bool** value can successfully be stored in a bit-field of any nonzero size. The address-of operator & shall not be applied to a bit-field, so there are no pointers to bit-fields. A non-const reference shall not be bound to a bit-field (??). [Note: If the initializer for a reference of type **const T&** is an lvalue that refers to a bit-field, the reference is bound to a temporary initialized to hold the value of the bit-field; the reference is not bound to the bit-field directly. See ??.. —end note]
- 4 If the value **true** or **false** is stored into a bit-field of type **bool** of any size (including a one bit bit-field), the original **bool** value and the value of the bit-field shall compare equal. If the value of an enumerator is stored into a bit-field of the same enumeration type and the number of bits in the bit-field is large enough to hold all the values of that enumeration type (??), the original enumerator value and the value of the bit-field shall compare equal. [Example:

```
enum BOOL { FALSE=0, TRUE=1 };
struct A {
    BOOL b:1;
};
A a;
void f() {
    a.b = TRUE;
    if (a.b == TRUE)           // yields true
        { /* ... */ }
}
```

—end example]

### 12.2.5 Nested class declarations

[class.nest]

- 1 A class can be declared within another class. A class declared within another is called a *nested class*. The name of a nested class is local to its enclosing class. The nested class is in the scope of its enclosing class. [Note: See ?? for restrictions on the use of non-static data members and non-static member functions. —end note]

[Example:

```
int x;
int y;
```

```

struct enclose {
    int x;
    static int s;

    struct inner {
        void f(int i) {
            int a = sizeof(x);           // OK: operand of sizeof is an unevaluated operand
            x = i;                      // error: assign to enclose::x
            s = i;                      // OK: assign to enclose::s
            ::x = i;                   // OK: assign to global x
            y = i;                      // OK: assign to global y
        }
        void g(enclose* p, int i) {
            p->x = i;                // OK: assign to enclose::x
        }
    };
};

inner* p = 0;                         // error: inner not in scope
— end example]

```

- <sup>2</sup> Member functions and static data members of a nested class can be defined in a namespace scope enclosing the definition of their class. [Example:

```

struct enclose {
    struct inner {
        static int x;
        void f(int i);
    };
};

int enclose::inner::x = 1;

void enclose::inner::f(int i) { /* ... */ }
— end example]

```

- <sup>3</sup> If class X is defined in a namespace scope, a nested class Y may be declared in class X and later defined in the definition of class X or be later defined in a namespace scope enclosing the definition of class X. [Example:

```

class E {
    class I1;                  // forward declaration of nested class
    class I2;
    class I1 { };              // definition of nested class
};

class E::I2 { };                // definition of nested class
— end example]

```

- <sup>4</sup> Like a member function, a friend function (??) defined within a nested class is in the lexical scope of that class; it obeys the same rules for name binding as a static member function of that class (??), but it has no special access rights to members of an enclosing class.

### 12.2.6 Nested type names

[**class.nested.type**]

- <sup>1</sup> Type names obey exactly the same scope rules as other names. In particular, type names defined within a class definition cannot be used outside their class without qualification. [*Example:*

```
struct X {
    typedef int I;
    class Y { /* ... */ };
    I a;
};

I b;           // error
Y c;           // error
X::Y d;        // OK
X::I e;        // OK

— end example]
```

### 12.3 Unions

[**class.union**]

- <sup>1</sup> In a union, a non-static data member is *active* if its name refers to an object whose lifetime has begun and has not ended (??). At most one of the non-static data members of an object of union type can be active at any time, that is, the value of at most one of the non-static data members can be stored in a union at any time. [*Note:* One special guarantee is made in order to simplify the use of unions: If a standard-layout union contains several standard-layout structs that share a common initial sequence (??), and if a non-static data member of an object of this standard-layout union type is active and is one of the standard-layout structs, it is permitted to inspect the common initial sequence of any of the standard-layout struct members; see ??.  
— end note]
- <sup>2</sup> The size of a union is sufficient to contain the largest of its non-static data members. Each non-static data member is allocated as if it were the sole member of a struct. [*Note:* A union object and its non-static data members are pointer-interconvertible (??, ??). As a consequence, all non-static data members of a union object have the same address. — end note]
- <sup>3</sup> A union can have member functions (including constructors and destructors), but it shall not have virtual (??) functions. A union shall not have base classes. A union shall not be used as a base class. If a union contains a non-static data member of reference type the program is ill-formed. [*Note:* Absent default member initializers (??), if any non-static data member of a union has a non-trivial default constructor (??), copy constructor (??), move constructor (??), copy assignment operator (??), move assignment operator (??), or destructor (??), the corresponding member function of the union must be user-provided or it will be implicitly deleted (??) for the union. — end note]
- <sup>4</sup> [*Example:* Consider the following union:

```
union U {
    int i;
    float f;
    std::string s;
};
```

Since `std::string` (??) declares non-trivial versions of all of the special member functions, `U` will have an implicitly deleted default constructor, copy/move constructor, copy/move assignment operator, and destructor. To use `U`, some or all of these member functions must be user-provided. — end example]

- <sup>5</sup> When the left operand of an assignment operator involves a member access expression (??) that nominates a union member, it may begin the lifetime of that union member, as described below. For an expression E, define the set S(E) of subexpressions of E as follows:

- (5.1) — If E is of the form A.B, S(E) contains the elements of S(A), and also contains A.B if B names a union member of a non-class, non-array type, or of a class type with a trivial default constructor that is not deleted, or an array of such types.
- (5.2) — If E is of the form A[B] and is interpreted as a built-in array subscripting operator, S(E) is S(A) if A is of array type, S(B) if B is of array type, and empty otherwise.
- (5.3) — Otherwise, S(E) is empty.

In an assignment expression of the form E1 = E2 that uses either the built-in assignment operator (??) or a trivial assignment operator (??), for each element X of S(E1), if modification of X would have undefined behavior under ??, an object of the type of X is implicitly created in the nominated storage; no initialization is performed and the beginning of its lifetime is sequenced after the value computation of the left and right operands and before the assignment. [Note: This ends the lifetime of the previously-active member of the union, if any (??). —end note] [Example:

```

union A { int x; int y[4]; };
struct B { A a; };
union C { B b; int k; };
int f() {
    C c;                      // does not start lifetime of any union member
    c.b.a.y[3] = 4;            // OK: S(c.b.a.y[3]) contains c.b and c.b.a.y;
                               // creates objects to hold union members c.b and c.b.a.y
    return c.b.a.y[3];         // OK: c.b.a.y refers to newly created object (see ??)
}

struct X { const int a; int b; };
union Y { X x; int k; };
void g() {
    Y y = { { 1, 2 } };      // OK, y.x is active union member (??)
    int n = y.x.a;
    y.k = 4;                 // OK: ends lifetime of y.x, y.k is active member of union
                               // undefined behavior: y.x.b modified outside its lifetime,
                               // S(y.x.b) is empty because X's default constructor is deleted,
                               // so union member y.x's lifetime does not implicitly start
}

```

—end example]

- <sup>6</sup> [Note: In general, one must use explicit destructor calls and placement new-expression to change the active member of a union. —end note] [Example: Consider an object u of a union type U having non-static data members m of type M and n of type N. If M has a non-trivial destructor and N has a non-trivial constructor (for instance, if they declare or inherit virtual functions), the active member of u can be safely switched from m to n using the destructor and placement new-expression as follows:

```

u.m.~M();
new (&u.n) N;

```

—end example]

### 12.3.1 Anonymous unions

[**class.union.anon**]

- <sup>1</sup> A union of the form

```
union { member-specification } ;
```

is called an *anonymous union*; it defines an unnamed type and an unnamed object of that type called an *anonymous union object*. Each *member-declaration* in the *member-specification* of an anonymous union shall either define a non-static data member or be a *static\_assert-declaration*. [ *Note*: Nested types, anonymous unions, and functions cannot be declared within an anonymous union. — *end note*] The names of the members of an anonymous union shall be distinct from the names of any other entity in the scope in which the anonymous union is declared. For the purpose of name lookup, after the anonymous union definition, the members of the anonymous union are considered to have been defined in the scope in which the anonymous union is declared. [ *Example*:

```
void f() {
    union { int a; const char* p; };
    a = 1;
    p = "Jennifer";
}
```

Here **a** and **p** are used like ordinary (non-member) variables, but since they are union members they have the same address. — *end example* ]

- <sup>2</sup> Anonymous unions declared in a named namespace or in the global namespace shall be declared **static**. Anonymous unions declared at block scope shall be declared with any storage class allowed for a block-scope variable, or with no storage class. A storage class is not allowed in a declaration of an anonymous union in a class scope. An anonymous union shall not have private or protected members (??). An anonymous union shall not have member functions.

- <sup>3</sup> A union for which objects, pointers, or references are declared is not an anonymous union. [ *Example*:

```
void f() {
    union { int aa; char* p; } obj, *ptr = &obj;
    aa = 1;           // error
    ptr->aa = 1;     // OK
}
```

The assignment to plain **aa** is ill-formed since the member name is not visible outside the union, and even if it were visible, it is not associated with any particular object. — *end example* ] [ *Note*: Initialization of unions with no user-declared constructors is described in ?? . — *end note* ]

- <sup>4</sup> A *union-like class* is a union or a class that has an anonymous union as a direct member. A union-like class **X** has a set of *variant members*. If **X** is a union, a non-static data member of **X** that is not an anonymous union is a variant member of **X**. In addition, a non-static data member of an anonymous union that is a member of **X** is also a variant member of **X**. At most one variant member of a union may have a default member initializer. [ *Example*:

```
union U {
    int x = 0;
    union {
        int k;
    };
    union {
        int z;
```

```

    int y = 1;      // error: initialization for second variant member of U
};

};

— end example]

```

## 12.4 Local class declarations

[class.local]

- <sup>1</sup> A class can be declared within a function definition; such a class is called a *local* class. The name of a local class is local to its enclosing scope. The local class is in the scope of the enclosing scope, and has the same access to names outside the function as does the enclosing function. [Note: A declaration in a local class cannot odr-use (??) a local entity from an enclosing scope. — end note] [Example:

```

int x;
void f() {
    static int s;
    int x;
    const int N = 5;
    extern int q();
    int arr[2];
    auto [y, z] = arr;

    struct local {
        int g() { return x; }           // error: odr-use of non-odr-usable variable x
        int h() { return s; }           // OK
        int k() { return ::x; }         // OK
        int l() { return q(); }         // OK
        int m() { return N; }          // OK: not an odr-use
        int* n() { return &N; }         // error: odr-use of non-odr-usable variable N
        int p() { return y; }           // error: odr-use of non-odr-usable structured binding y
    };
}

local* p = 0;                      // error: local not in scope
— end example]

```

- <sup>2</sup> An enclosing function has no special access to members of the local class; it obeys the usual access rules (??). Member functions of a local class shall be defined within their class definition, if they are defined at all.
- <sup>3</sup> If class X is a local class a nested class Y may be declared in class X and later defined in the definition of class X or be later defined in the same scope as the definition of class X. A class nested within a local class is a local class.
- <sup>4</sup> A local class shall not have static data members.

## 13 Derived classes

[class.derived]

- <sup>1</sup> A list of base classes can be specified in a class definition using the notation:

```

base-clause:
  : base-specifier-list

base-specifier-list:
  base-specifier ...opt
  base-specifier-list , base-specifier ...opt

base-specifier:
  attribute-specifier-seqopt class-or-decltype
  attribute-specifier-seqopt virtual access-specifieropt class-or-decltype
  attribute-specifier-seqopt access-specifier virtualopt class-or-decltype

class-or-decltype:
  nested-name-specifieropt class-name
  nested-name-specifier template simple-template-id
  decltype-specifier

access-specifier:
  private
  protected
  public

```

The optional *attribute-specifier-seq* appertains to the *base-specifier*.

- <sup>2</sup> A *class-or-decltype* shall denote a class type that is not an incompletely defined class (??). The class denoted by the *class-or-decltype* of a *base-specifier* is called a *direct base class* for the class being defined. During the lookup for a base class name, non-type names are ignored (??). If the name found is not a *class-name*, the program is ill-formed. A class B is a base class of a class D if it is a direct base class of D or a direct base class of one of D's base classes. A class is an *indirect* base class of another if it is a base class but not a direct base class. A class is said to be (directly or indirectly) *derived* from its (direct or indirect) base classes. [ *Note*: See ?? for the meaning of *access-specifier*. — *end note* ] Unless redeclared in the derived class, members of a base class are also considered to be members of the derived class. Members of a base class other than constructors are said to be *inherited* by the derived class. Constructors of a base class can also be inherited as described in ???. Inherited members can be referred to in expressions in the same manner as other members of the derived class, unless their names are hidden or ambiguous (??). [ *Note*: The scope resolution operator :: (??) can be used to refer to a direct or indirect base member explicitly. This allows access to a name that has been redeclared in the derived class. A derived class can itself serve as a base class subject to access control; see ???. A pointer to a derived class can be implicitly converted to a pointer to an accessible unambiguous base class (??). An lvalue of a derived class type can be bound to a reference to an accessible unambiguous base class (??). — *end note* ]

- <sup>3</sup> The *base-specifier-list* specifies the type of the *base class subobjects* contained in an object of the derived class type. [ *Example*:

```

struct Base {
  int a, b, c;
};

```

```

struct Derived : Base {
    int b;
};

struct Derived2 : Derived {
    int c;
};

```

Here, an object of class `Derived2` will have a subobject of class `Derived` which in turn will have a subobject of class `Base`. — *end example*]

- <sup>4</sup> A *base-specifier* followed by an ellipsis is a pack expansion (??).
- <sup>5</sup> The order in which the base class subobjects are allocated in the most derived object (??) is unspecified. [ *Note*: A derived class and its base class subobjects can be represented by a directed acyclic graph (DAG) where an arrow means “directly derived from”. An arrow need not have a physical representation in memory. A DAG of subobjects is often referred to as a “subobject lattice”.

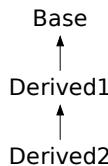

Figure 2 — Directed acyclic graph

— *end note*]

- <sup>6</sup> [ *Note*: Initialization of objects representing base classes can be specified in constructors; see ?? . — *end note*]
- <sup>7</sup> [ *Note*: A base class subobject might have a layout (??) different from the layout of a most derived object of the same type. A base class subobject might have a polymorphic behavior (??) different from the polymorphic behavior of a most derived object of the same type. A base class subobject may be of zero size (??); however, two subobjects that have the same class type and that belong to the same most derived object must not be allocated at the same address (??). — *end note*]

### 13.1 Multiple base classes

[**class.mi**]

- <sup>1</sup> A class can be derived from any number of base classes. [ *Note*: The use of more than one direct base class is often called multiple inheritance. — *end note*] [ *Example*:

```

class A { /* ... */;
class B { /* ... */;
class C { /* ... */;
class D : public A, public B, public C { /* ... */;

— end example]

```

- <sup>2</sup> [ *Note*: The order of derivation is not significant except as specified by the semantics of initialization by constructor (??), cleanup (??), and storage layout (??, ??). — *end note*]
- <sup>3</sup> A class shall not be specified as a direct base class of a derived class more than once. [ *Note*: A class can be an indirect base class more than once and can be a direct and an indirect base class. There are limited things that can be done with such a class. The non-static data members and member functions of the direct

base class cannot be referred to in the scope of the derived class. However, the static members, enumerations and types can be unambiguously referred to. — *end note*] [Example:

```
class X { /* ... */ };
class Y : public X, public X { /* ... */ };           // ill-formed
class L { public: int next; /* ... */ };
class A : public L { /* ... */ };
class B : public L { /* ... */ };
class C : public A, public B { void f(); /* ... */ }; // well-formed
class D : public A, public L { void f(); /* ... */ }; // well-formed
— end example]
```

- <sup>4</sup> A base class specifier that does not contain the keyword **virtual** specifies a *non-virtual base class*. A base class specifier that contains the keyword **virtual** specifies a *virtual base class*. For each distinct occurrence of a non-virtual base class in the class lattice of the most derived class, the most derived object (??) shall contain a corresponding distinct base class subobject of that type. For each distinct base class that is specified **virtual**, the most derived object shall contain a single base class subobject of that type.
- <sup>5</sup> [Note: For an object of class type **C**, each distinct occurrence of a (non-virtual) base class **L** in the class lattice of **C** corresponds one-to-one with a distinct **L** subobject within the object of type **C**. Given the class **C** defined above, an object of class **C** will have two subobjects of class **L** as shown in Figure ??.

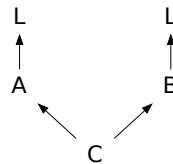

Figure 3 — Non-virtual base

In such lattices, explicit qualification can be used to specify which subobject is meant. The body of function **C::f** could refer to the member **next** of each **L** subobject:

```
void C::f() { A::next = B::next; }           // well-formed
```

Without the **A::** or **B::** qualifiers, the definition of **C::f** above would be ill-formed because of ambiguity (??). — *end note*]

- <sup>6</sup> [Note: In contrast, consider the case with a virtual base class:

```
class V { /* ... */ };
class A : virtual public V { /* ... */ };
class B : virtual public V { /* ... */ };
class C : public A, public B { /* ... */ };
```

For an object **c** of class type **C**, a single subobject of type **V** is shared by every base class subobject of **c** that has a **virtual** base class of type **V**. Given the class **C** defined above, an object of class **C** will have one subobject of class **V**, as shown in Figure ??.. — *end note*]

- <sup>7</sup> [Note: A class can have both virtual and non-virtual base classes of a given type.

```
class B { /* ... */;
class X : virtual public B { /* ... */ };
```

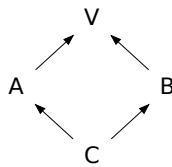

Figure 4 — Virtual base

```

class Y : virtual public B { /* ... */ };
class Z : public B { /* ... */ };
class AA : public X, public Y, public Z { /* ... */ };

```

For an object of class AA, all *virtual* occurrences of base class B in the class lattice of AA correspond to a single B subobject within the object of type AA, and every other occurrence of a (non-virtual) base class B in the class lattice of AA corresponds one-to-one with a distinct B subobject within the object of type AA. Given the class AA defined above, class AA has two subobjects of class B: Z's B and the virtual B shared by X and Y, as shown in Figure ??.

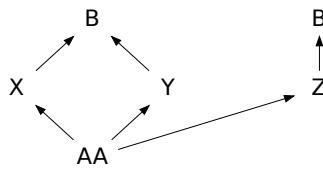

Figure 5 — Virtual and non-virtual base

— end note ]

## 13.2 Member name lookup

[**class.member.lookup**]

- <sup>1</sup> Member name lookup determines the meaning of a name (*id-expression*) in a class scope (??). Name lookup can result in an *ambiguity*, in which case the program is ill-formed. For an *id-expression*, name lookup begins in the class scope of `this`; for a *qualified-id*, name lookup begins in the scope of the *nested-name-specifier*. Name lookup takes place before access control (??, ??).
- <sup>2</sup> The following steps define the result of name lookup for a member name `f` in a class scope `C`.
- <sup>3</sup> The *lookup set* for `f` in `C`, called  $S(f, C)$ , consists of two component sets: the *declaration set*, a set of members named `f`; and the *subobject set*, a set of subobjects where declarations of these members (possibly including *using-declarations*) were found. In the declaration set, *using-declarations* are replaced by the set of designated members that are not hidden or overridden by members of the derived class (??), and type declarations (including injected-class-names) are replaced by the types they designate.  $S(f, C)$  is calculated as follows:
- <sup>4</sup> If `C` contains a declaration of the name `f`, the declaration set contains every declaration of `f` declared in `C` that satisfies the requirements of the language construct in which the lookup occurs. [ *Note*: Looking up a name in an *elaborated-type-specifier* (??) or *base-specifier* (??), for instance, ignores all non-type declarations, while looking up a name in a *nested-name-specifier* (??) ignores function, variable, and enumerator declarations. As another example, looking up a name in a *using-declaration* (??) includes the declaration of a class or enumeration that would ordinarily be hidden by another declaration of that name in the same scope. — end

*note]* If the resulting declaration set is not empty, the subobject set contains  $C$  itself, and calculation is complete.

- 5 Otherwise (i.e.,  $C$  does not contain a declaration of  $f$  or the resulting declaration set is empty),  $S(f, C)$  is initially empty. If  $C$  has base classes, calculate the lookup set for  $f$  in each direct base class subobject  $B_i$ , and merge each such lookup set  $S(f, B_i)$  in turn into  $S(f, C)$ .
- 6 The following steps define the result of merging lookup set  $S(f, B_i)$  into the intermediate  $S(f, C)$ :
  - (6.1) — If each of the subobject members of  $S(f, B_i)$  is a base class subobject of at least one of the subobject members of  $S(f, C)$ , or if  $S(f, B_i)$  is empty,  $S(f, C)$  is unchanged and the merge is complete. Conversely, if each of the subobject members of  $S(f, C)$  is a base class subobject of at least one of the subobject members of  $S(f, B_i)$ , or if  $S(f, C)$  is empty, the new  $S(f, C)$  is a copy of  $S(f, B_i)$ .
  - (6.2) — Otherwise, if the declaration sets of  $S(f, B_i)$  and  $S(f, C)$  differ, the merge is ambiguous: the new  $S(f, C)$  is a lookup set with an invalid declaration set and the union of the subobject sets. In subsequent merges, an invalid declaration set is considered different from any other.
  - (6.3) — Otherwise, the new  $S(f, C)$  is a lookup set with the shared set of declarations and the union of the subobject sets.

- 7 The result of name lookup for  $f$  in  $C$  is the declaration set of  $S(f, C)$ . If it is an invalid set, the program is ill-formed. [*Example*:

```

struct A { int x; }; // S(x,A) = { { A::x }, { A } }
struct B { float x; }; // S(x,B) = { { B::x }, { B } }
struct C: public A, public B { }; // S(x,C) = { invalid, { A in C, B in C } }
struct D: public virtual C { }; // S(x,D) = S(x,C)
struct E: public virtual C { char x; }; // S(x,E) = { { E::x }, { E } }
struct F: public D, public E { }; // S(x,F) = S(x,E)

int main() {
    F f;
    f.x = 0; // OK, lookup finds E::x
}

```

$S(x, F)$  is unambiguous because the  $A$  and  $B$  base class subobjects of  $D$  are also base class subobjects of  $E$ , so  $S(x, D)$  is discarded in the first merge step. — *end example*]

- 8 If the name of an overloaded function is unambiguously found, overload resolution (??) also takes place before access control. Ambiguities can often be resolved by qualifying a name with its class name. [*Example*:

```

struct A {
    int f();
};

struct B {
    int f();
};

struct C : A, B {
    int f() { return A::f() + B::f(); }
};

```

— *end example*]

- 9 [*Note:* A static member, a nested type or an enumerator defined in a base class  $T$  can unambiguously be found even if an object has more than one base class subobject of type  $T$ . Two base class subobjects share

the non-static member subobjects of their common virtual base classes. — *end note*] [Example:

```
struct V {
    int v;
};

struct A {
    int a;
    static int s;
    enum { e };
};

struct B : A, virtual V {};
struct C : A, virtual V {};
struct D : B, C {};

void f(D* pd) {
    pd->v++;           // OK: only one v (virtual)
    pd->s++;           // OK: only one s (static)
    int i = pd->e;     // OK: only one e (enumerator)
    pd->a++;           // error, ambiguous: two as in D
}
```

— *end example*]

- <sup>10</sup> [Note: When virtual base classes are used, a hidden declaration can be reached along a path through the subobject lattice that does not pass through the hiding declaration. This is not an ambiguity. The identical use with non-virtual base classes is an ambiguity; in that case there is no unique instance of the name that hides all the others. — *end note*] [Example:

```
struct V { int f(); int x; };
struct W { int g(); int y; };
struct B : virtual V, W {
    int f(); int x;
    int g(); int y;
};
struct C : virtual V, W {};

struct D : B, C { void glorp(); };
```

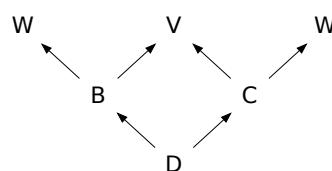

Figure 6 — Name lookup

The names declared in V and the left-hand instance of W are hidden by those in B, but the names declared in the right-hand instance of W are not hidden at all.

```
void D::glorp() {
    x++;           // OK: B::x hides V::x
    f();           // OK: B::f() hides V::f()
```

```

    y++;           // error: B::y and C's W::y
    g();           // error: B::g() and C's W::g()
}

— end example]

```

- 11 An explicit or implicit conversion from a pointer to or an expression designating an object of a derived class to a pointer or reference to one of its base classes shall unambiguously refer to a unique object representing the base class. [ *Example*:

```

struct V {};
struct A {};
struct B : A, virtual V {};
struct C : A, virtual V {};
struct D : B, C {};

void g() {
    D d;
    B* pb = &d;
    A* pa = &d;      // error, ambiguous: C's A or B's A?
    V* pv = &d;      // OK: only one V subobject
}

```

— end example]

- 12 [ *Note*: Even if the result of name lookup is unambiguous, use of a name found in multiple subobjects might still be ambiguous (??, ??, ??). — end note] [ *Example*:

```

struct B1 {
    void f();
    static void f(int);
    int i;
};

struct B2 {
    void f(double);
};

struct I1: B1 {};
struct I2: B1 {};

struct D: I1, I2, B2 {
    using B1::f;
    using B2::f;
    void g() {
        f();           // Ambiguous conversion of this
        f(0);         // Unambiguous (static)
        f(0.0);       // Unambiguous (only one B2)
        int B1::* mpB1 = &D::i; // Unambiguous
        int D::* mpD = &D::i;   // Ambiguous conversion
    }
};

```

— end example]

### 13.3 Virtual functions

[**class.virtual**]

- <sup>1</sup> [*Note*: Virtual functions support dynamic binding and object-oriented programming. — *end note*] A class that declares or inherits a virtual function is called a *polymorphic class*.
- <sup>2</sup> If a virtual member function `vf` is declared in a class `Base` and in a class `Derived`, derived directly or indirectly from `Base`, a member function `vf` with the same name, parameter-type-list (??), cv-qualification, and ref-qualifier (or absence of same) as `Base::vf` is declared, then `Derived::vf` is also virtual (whether or not it is so declared) and it *overrides*<sup>112</sup> `Base::vf`. For convenience we say that any virtual function overrides itself. A virtual member function `C::vf` of a class object `S` is a *final overrider* unless the most derived class (??) of which `S` is a base class subobject (if any) declares or inherits another member function that overrides `vf`. In a derived class, if a virtual member function of a base class subobject has more than one final overrider the program is ill-formed. [*Example*:

```
struct A {
    virtual void f();
};

struct B : virtual A {
    virtual void f();
};

struct C : B, virtual A {
    using A::f;
};

void foo() {
    C c;
    c.f();           // calls B::f, the final overrider
    c.C::f();        // calls A::f because of the using-declaration
}
```

— *end example*]

[*Example*:

```
struct A { virtual void f(); };
struct B : A {};
struct C : A { void f(); };
struct D : B, C {};
// OK: A::f and C::f are the final overriders
// for the B and C subobjects, respectively
```

— *end example*]

- <sup>3</sup> [*Note*: A virtual member function does not have to be visible to be overridden, for example,

```
struct B {
    virtual void f();
};

struct D : B {
    void f(int);
};
```

<sup>112</sup>) A function with the same name but a different parameter list (??) as a virtual function is not necessarily virtual and does not override. The use of the `virtual` specifier in the declaration of an overriding function is legal but redundant (has empty semantics). Access control (??) is not considered in determining overriding.

```
struct D2 : D {
    void f();
};
```

the function `f(int)` in class `D` hides the virtual function `f()` in its base class `B`; `D::f(int)` is not a virtual function. However, `f()` declared in class `D2` has the same name and the same parameter list as `B::f()`, and therefore is a virtual function that overrides the function `B::f()` even though `B::f()` is not visible in class `D2`. — *end note*]

- <sup>4</sup> If a virtual function `f` in some class `B` is marked with the *virt-specifier* `final` and in a class `D` derived from `B` a function `D::f` overrides `B::f`, the program is ill-formed. [Example:

```
struct B {
    virtual void f() const final;
};
```

```
struct D : B {
    void f() const;      // error: D::f attempts to override final B::f
};
```

— *end example*]

- <sup>5</sup> If a virtual function is marked with the *virt-specifier* `override` and does not override a member function of a base class, the program is ill-formed. [Example:

```
struct B {
    virtual void f(int);
};

struct D : B {
    virtual void f(long) override; // error: wrong signature overriding B::f
    virtual void f(int) override;  // OK
};

— end example]
```

- <sup>6</sup> A virtual function shall not have a trailing *requires-clause* (??). [Example:

```
struct A {
    virtual void f() requires true; // error: virtual function cannot be constrained (??)
};
```

— *end example*]

- <sup>7</sup> Even though destructors are not inherited, a destructor in a derived class overrides a base class destructor declared `virtual`; see ?? and ??.

- <sup>8</sup> The return type of an overriding function shall be either identical to the return type of the overridden function or *covariant* with the classes of the functions. If a function `D::f` overrides a function `B::f`, the return types of the functions are covariant if they satisfy the following criteria:

- (8.1) — both are pointers to classes, both are lvalue references to classes, or both are rvalue references to classes<sup>113</sup>
- (8.2) — the class in the return type of `B::f` is the same class as the class in the return type of `D::f`, or is an unambiguous and accessible direct or indirect base class of the class in the return type of `D::f`

---

<sup>113</sup>) Multi-level pointers to classes or references to multi-level pointers to classes are not allowed.

- (8.3) — both pointers or references have the same cv-qualification and the class type in the return type of `D::f` has the same cv-qualification as or less cv-qualification than the class type in the return type of `B::f`.
- 9 If the class type in the covariant return type of `D::f` differs from that of `B::f`, the class type in the return type of `D::f` shall be complete at the point of declaration of `D::f` or shall be the class type `D`. When the overriding function is called as the final overrider of the overridden function, its result is converted to the type returned by the (statically chosen) overridden function (??). [Example:

```

class B {};
class D : private B { friend class Derived; };
struct Base {
    virtual void vf1();
    virtual void vf2();
    virtual void vf3();
    virtual B* vf4();
    virtual B* vf5();
    void f();
};

struct No_good : public Base {
    D* vf4();           // error: B (base class of D) inaccessible
};

class A;
struct Derived : public Base {
    void vf1();        // virtual and overrides Base::vf1()
    void vf2(int);    // not virtual, hides Base::vf2()
    char vf3();        // error: invalid difference in return type only
    D* vf4();          // OK: returns pointer to derived class
    A* vf5();          // error: returns pointer to incomplete class
    void f();
};

void g() {
    Derived d;
    Base* bp = &d;           // standard conversion:
                            // Derived* to Base*
    bp->vf1();             // calls Derived::vf1()
    bp->vf2();             // calls Base::vf2()
    bp->f();               // calls Base::f() (not virtual)
    B* p = bp->vf4();     // calls Derived::vf4() and converts the
                            // result to B*
    Derived* dp = &d;
    D* q = dp->vf4();     // calls Derived::vf4() and does not
                            // convert the result to B*
    dp->vf2();             // ill-formed: argument mismatch
}

```

— end example]

<sup>10</sup> [Note: The interpretation of the call of a virtual function depends on the type of the object for which it is called (the dynamic type), whereas the interpretation of a call of a non-virtual member function depends only on the type of the pointer or reference denoting that object (the static type) (??). —end note]

<sup>11</sup> [Note: The `virtual` specifier implies membership, so a virtual function cannot be a non-member (??) function. Nor can a virtual function be a static member, since a virtual function call relies on a specific object for determining which function to invoke. A virtual function declared in one class can be declared a friend (??) in another class. —end note]

<sup>12</sup> A virtual function declared in a class shall be defined, or declared pure (??) in that class, or both; no diagnostic is required (??).

<sup>13</sup> [Example: Here are some uses of virtual functions with multiple base classes:

```
struct A {
    virtual void f();
};

struct B1 : A { // note non-virtual derivation
    void f();
};

struct B2 : A {
    void f();
};

struct D : B1, B2 { // D has two separate A subobjects
};

void foo() {
    D d;
    // A* ap = &d; // would be ill-formed: ambiguous
    B1* b1p = &d;
    A* ap = b1p;
    D* dp = &d;
    ap->f(); // calls D::B1::f
    dp->f(); // ill-formed: ambiguous
}
```

In class D above there are two occurrences of class A and hence two occurrences of the virtual member function `A::f`. The final overrider of `B1::A::f` is `B1::f` and the final overrider of `B2::A::f` is `B2::f`. —end example]

<sup>14</sup> [Example: The following example shows a function that does not have a unique final overrider:

```
struct A {
    virtual void f();
};

struct VB1 : virtual A { // note virtual derivation
    void f();
};

```

```

struct VB2 : virtual A {
    void f();
};

struct Error : VB1, VB2 {           // ill-formed
};

struct Okay : VB1, VB2 {
    void f();
};

```

Both `VB1::f` and `VB2::f` override `A::f` but there is no overrider of both of them in class `Error`. This example is therefore ill-formed. Class `Okay` is well-formed, however, because `Okay::f` is a final overrider.  
— end example]

- <sup>15</sup> [Example: The following example uses the well-formed classes from above.

```

struct VB1a : virtual A {           // does not declare f
};

struct Da : VB1a, VB2 {
};

void foe() {
    VB1a* vb1ap = new Da;
    vb1ap->f();                  // calls VB2::f
}

```

— end example]

- <sup>16</sup> Explicit qualification with the scope operator (??) suppresses the virtual call mechanism. [Example:

```

class B { public: virtual void f(); };
class D : public B { public: void f(); };

void D::f() { /* ... */ B::f(); }

```

Here, the function call in `D::f` really does call `B::f` and not `D::f`. — end example]

- <sup>17</sup> A function with a deleted definition (??) shall not override a function that does not have a deleted definition. Likewise, a function that does not have a deleted definition shall not override a function with a deleted definition.

### 13.4 Abstract classes

[**class.abstract**]

- <sup>1</sup> [Note: The abstract class mechanism supports the notion of a general concept, such as a `shape`, of which only more concrete variants, such as `circle` and `square`, can actually be used. An abstract class can also be used to define an interface for which derived classes provide a variety of implementations. — end note]
- <sup>2</sup> An *abstract class* is a class that can be used only as a base class of some other class; no objects of an abstract class can be created except as subobjects of a class derived from it. A class is abstract if it has at least one *pure virtual function*. [Note: Such a function might be inherited: see below. — end note] A virtual function is specified *pure* by using a *pure-specifier* (??) in the function declaration in the class definition. A pure virtual function need be defined only if called with, or as if with (??), the *qualified-id* syntax (??). [Example:

```

class point { /* ... */ };
class shape {           // abstract class
    point center;
public:
    point where() { return center; }
    void move(point p) { center=p; draw(); }
    virtual void rotate(int) = 0; // pure virtual
    virtual void draw() = 0;      // pure virtual
};

— end example] [Note: A function declaration cannot provide both a pure-specifier and a definition — end note] [Example:

```

```

struct C {
    virtual void f() = 0 { };      // ill-formed
};

— end example]

```

- 3 An abstract class shall not be used as a parameter type, as a function return type, or as the type of an explicit conversion. Pointers and references to an abstract class can be declared. [Example:

```

shape x;           // error: object of abstract class
shape* p;          // OK
shape f();         // error
void g(shape);     // error
shape& h(shape&); // OK

```

— end example]

- 4 A class is abstract if it contains or inherits at least one pure virtual function for which the final overrider is pure virtual. [Example:

```

class ab_circle : public shape {
    int radius;
public:
    void rotate(int) { }
    // ab_circle::draw() is a pure virtual
};

```

Since `shape::draw()` is a pure virtual function `ab_circle::draw()` is a pure virtual by default. The alternative declaration,

```

class circle : public shape {
    int radius;
public:
    void rotate(int) { }
    void draw();           // a definition is required somewhere
};

```

would make class `circle` non-abstract and a definition of `circle::draw()` must be provided. — end example]

- 5 [Note: An abstract class can be derived from a class that is not abstract, and a pure virtual function may override a virtual function which is not pure. — end note]

- <sup>6</sup> Member functions can be called from a constructor (or destructor) of an abstract class; the effect of making a virtual call (??) to a pure virtual function directly or indirectly for the object being created (or destroyed) from such a constructor (or destructor) is undefined.

## 14 Member access control

[class.access]

<sup>1</sup> A member of a class can be

- (1.1) — private; that is, its name can be used only by members and friends of the class in which it is declared.
- (1.2) — protected; that is, its name can be used only by members and friends of the class in which it is declared, by classes derived from that class, and by their friends (see ??).
- (1.3) — public; that is, its name can be used anywhere without access restriction.

<sup>2</sup> A member of a class can also access all the names to which the class has access. A local class of a member function may access the same names that the member function itself may access.<sup>114</sup>

<sup>3</sup> Members of a class defined with the keyword **class** are **private** by default. Members of a class defined with the keywords **struct** or **union** are public by default. [Example:

```
class X {
    int a;           // X::a is private by default
};

struct S {
    int a;           // S::a is public by default
};

— end example]
```

<sup>4</sup> Access control is applied uniformly to all names, whether the names are referred to from declarations or expressions. [Note: Access control applies to names nominated by friend declarations (??) and *using-declarations* (??). — end note] In the case of overloaded function names, access control is applied to the function selected by overload resolution. [Note: Because access control applies to names, if access control is applied to a **typedef** name, only the accessibility of the **typedef** name itself is considered. The accessibility of the entity referred to by the **typedef** is not considered. For example,

```
class A {
    class B { };
public:
    typedef B BB;
};

void f() {
    A::BB x;           // OK, typedef name A::BB is public
    A::B y;           // access error, A::B is private
}

— end note]
```

<sup>5</sup> It should be noted that it is *access* to members and base classes that is controlled, not their *visibility*. Names of members are still visible, and implicit conversions to base classes are still considered, when those members and base classes are inaccessible. The interpretation of a given construct is established without regard to

---

<sup>114)</sup> Access permissions are thus transitive and cumulative to nested and local classes.

access control. If the interpretation established makes use of inaccessible member names or base classes, the construct is ill-formed.

- 6 All access controls in ?? affect the ability to access a class member name from the declaration of a particular entity, including parts of the declaration preceding the name of the entity being declared and, if the entity is a class, the definitions of members of the class appearing outside the class's *member-specification*. [Note: This access also applies to implicit references to constructors, conversion functions, and destructors. —end note]

- 7 [Example:

```
class A {
    typedef int I;      // private member
    I f();
    friend I g(I);
    static I x;
    template<int> struct Q;
    template<int> friend struct R;
protected:
    struct B { };
};

A::I A::f() { return 0; }
A::I g(A::I p = A::x);
A::I g(A::I p) { return 0; }
A::I A::x = 0;
template<A::I> struct A::Q { };
template<A::I> struct R { };

struct D: A::B, A { };
```

Here, all the uses of `A::I` are well-formed because `A::f`, `A::x`, and `A::Q` are members of class `A` and `g` and `R` are friends of class `A`. This implies, for example, that access checking on the first use of `A::I` must be deferred until it is determined that this use of `A::I` is as the return type of a member of class `A`. Similarly, the use of `A::B` as a *base-specifier* is well-formed because `D` is derived from `A`, so checking of *base-specifiers* must be deferred until the entire *base-specifier-list* has been seen. —end example]

- 8 The names in a default argument (??) are bound at the point of declaration, and access is checked at that point rather than at any points of use of the default argument. Access checking for default arguments in function templates and in member functions of class templates is performed as described in ??.
- 9 The names in a default *template-argument* (??) have their access checked in the context in which they appear rather than at any points of use of the default *template-argument*. [Example:

```
class B { };
template <class T> class C {
protected:
    typedef T TT;
};

template <class U, class V = typename U::TT>
class D : public U { };

D <C<B> *> d;           // access error, C::TT is protected
```

— end example ]

## 14.1 Access specifiers

[class.access.spec]

- 1 Member declarations can be labeled by an *access-specifier* (??):

*access-specifier* : *member-specification*<sub>opt</sub>

An *access-specifier* specifies the access rules for members following it until the end of the class or until another *access-specifier* is encountered. [ Example:

```
class X {
    int a;           // X::a is private by default: class used
public:
    int b;           // X::b is public
    int c;           // X::c is public
};
```

— end example ]

- 2 Any number of access specifiers is allowed and no particular order is required. [ Example:

```
struct S {
    int a;           // S::a is public by default: struct used
protected:
    int b;           // S::b is protected
private:
    int c;           // S::c is private
public:
    int d;           // S::d is public
};
```

— end example ]

- 3 [ Note: The effect of access control on the order of allocation of data members is described in ?? . — end note ]

- 4 When a member is redeclared within its class definition, the access specified at its redeclaration shall be the same as at its initial declaration. [ Example:

```
struct S {
    class A;
    enum E : int;
private:
    class A { };      // error: cannot change access
    enum E: int { e0 }; // error: cannot change access
};
```

— end example ]

- 5 [ Note: In a derived class, the lookup of a base class name will find the injected-class-name instead of the name of the base class in the scope in which it was declared. The injected-class-name might be less accessible than the name of the base class in the scope in which it was declared. — end note ]

[ Example:

```
class A { };
class B : private A { };
class C : public B {
    A* p;           // error: injected-class-name A is inaccessible
```

```
::A* q;           // OK
};

— end example]
```

## 14.2 Accessibility of base classes and base class members

[**class.access.base**]

- 1 If a class is declared to be a base class (??) for another class using the **public** access specifier, the public members of the base class are accessible as public members of the derived class and protected members of the base class are accessible as protected members of the derived class. If a class is declared to be a base class for another class using the **protected** access specifier, the public and protected members of the base class are accessible as protected members of the derived class. If a class is declared to be a base class for another class using the **private** access specifier, the public and protected members of the base class are accessible as private members of the derived class.<sup>115</sup>

- 2 In the absence of an *access-specifier* for a base class, **public** is assumed when the derived class is defined with the *class-key struct* and **private** is assumed when the class is defined with the *class-key class*. [Example:

```
class B { /* ... */ };
class D1 : private B { /* ... */ };
class D2 : public B { /* ... */ };
class D3 : B { /* ... */ };           // B private by default
struct D4 : public B { /* ... */ };
struct D5 : private B { /* ... */ };
struct D6 : B { /* ... */ };         // B public by default
class D7 : protected B { /* ... */ };
struct D8 : protected B { /* ... */ };
```

Here B is a public base of D2, D4, and D6, a private base of D1, D3, and D5, and a protected base of D7 and D8. — end example]

- 3 [Note: A member of a private base class might be inaccessible as an inherited member name, but accessible directly. Because of the rules on pointer conversions (??) and explicit casts (??), a conversion from a pointer to a derived class to a pointer to an inaccessible base class might be ill-formed if an implicit conversion is used, but well-formed if an explicit cast is used. For example,

```
class B {
public:
    int mi;           // non-static member
    static int si;   // static member
};
class D : private B {
};
class DD : public D {
    void f();
};

void DD::f() {
    mi = 3;          // error: mi is private in D
    si = 3;          // error: si is private in D
    ::B b;
```

<sup>115)</sup> As specified previously in ??, private members of a base class remain inaccessible even to derived classes unless friend declarations within the base class definition are used to grant access explicitly.

```

    b.mi = 3;                                // OK (b.mi is different from this->mi)
    b.si = 3;                                // OK (b.si is different from this->si)
    ::B::si = 3;                             // OK
    ::B* bp1 = this;                         // error: B is a private base class
    ::B* bp2 = (::B*)this;                   // OK with cast
    bp2->mi = 3;                            // OK: access through a pointer to B.
}

— end note]

```

<sup>4</sup> A base class B of N is *accessible* at R, if

- (4.1) — an invented public member of B would be a public member of N, or
- (4.2) — R occurs in a member or friend of class N, and an invented public member of B would be a private or protected member of N, or
- (4.3) — R occurs in a member or friend of a class P derived from N, and an invented public member of B would be a private or protected member of P, or
- (4.4) — there exists a class S such that B is a base class of S accessible at R and S is a base class of N accessible at R.

[ *Example:*

```

class B {
public:
    int m;
};

class S: private B {
    friend class N;
};

class N: private S {
    void f() {
        B* p = this;      // OK because class S satisfies the fourth condition above: B is a base class of N
                           // accessible in f() because B is an accessible base class of S and S is an accessible
                           // base class of N.
    }
};

```

— end example]

<sup>5</sup> If a base class is accessible, one can implicitly convert a pointer to a derived class to a pointer to that base class (??, ??). [ *Note:* It follows that members and friends of a class X can implicitly convert an X\* to a pointer to a private or protected immediate base class of X. — end note] The access to a member is affected by the class in which the member is named. This naming class is the class in which the member name was looked up and found. [ *Note:* This class can be explicit, e.g., when a *qualified-id* is used, or implicit, e.g., when a class member access operator (??) is used (including cases where an implicit “this->” is added). If both a class member access operator and a *qualified-id* are used to name the member (as in p->T::m), the class naming the member is the class denoted by the *nested-name-specifier* of the *qualified-id* (that is, T). — end note] A member m is accessible at the point R when named in class N if

- (5.1) — m as a member of N is public, or

- (5.2) —  $m$  as a member of  $N$  is private, and  $R$  occurs in a member or friend of class  $N$ , or
  - (5.3) —  $m$  as a member of  $N$  is protected, and  $R$  occurs in a member or friend of class  $N$ , or in a member of a class  $P$  derived from  $N$ , where  $m$  as a member of  $P$  is public, private, or protected, or
  - (5.4) — there exists a base class  $B$  of  $N$  that is accessible at  $R$ , and  $m$  is accessible at  $R$  when named in class  $B$ .
- [*Example:*

```
class B;
class A {
private:
    int i;
    friend void f(B*);
};
class B : public A {};
void f(B* p) {
    p->i = 1;           // OK: B* can be implicitly converted to A*, and f has access to i in A
}
```

— end example]

<sup>6</sup> If a class member access operator, including an implicit “`this->`”, is used to access a non-static data member or non-static member function, the reference is ill-formed if the left operand (considered as a pointer in the `..` operator case) cannot be implicitly converted to a pointer to the naming class of the right operand. [ *Note:* This requirement is in addition to the requirement that the member be accessible as named. — end note ]

### 14.3 Friends

[**class.friend**]

- <sup>1</sup> A friend of a class is a function or class that is given permission to use the private and protected member names from the class. A class specifies its friends, if any, by way of friend declarations. Such declarations give special access rights to the friends, but they do not make the nominated friends members of the befriended class. [*Example:* The following example illustrates the differences between members and friends:

```
class X {
    int a;
    friend void friend_set(X*, int);
public:
    void member_set(int);
};

void friend_set(X* p, int i) { p->a = i; }
void X::member_set(int i) { a = i; }

void f() {
    X obj;
    friend_set(&obj, 10);
    obj.member_set(10);
}

— end example]
```

- <sup>2</sup> Declaring a class to be a friend implies that the names of private and protected members from the class granting friendship can be accessed in the *base-specifiers* and member declarations of the befriended class. [*Example:*

```

class A {
    class B { };
    friend class X;
};

struct X : A::B { // OK: A::B accessible to friend
    A::B mx; // OK: A::B accessible to member of friend
    class Y {
        A::B my; // OK: A::B accessible to nested member of friend
    };
};

— end example] [Example:

class X {
    enum { a=100 };
    friend class Y;
};

class Y {
    int v[X::a]; // OK, Y is a friend of X
};

class Z {
    int v[X::a]; // error: X::a is private
};

— end example]

```

A class shall not be defined in a friend declaration. [Example:

```

class A {
    friend class B { }; // error: cannot define class in friend declaration
};

— end example]

```

- 3 A friend declaration that does not declare a function shall have one of the following forms:

```

friend elaborated-type-specifier ;
friend simple-type-specifier ;
friend typename-specifier ;

```

[Note: A friend declaration may be the *declaration* in a *template-declaration* (??, ??). — end note] If the type specifier in a **friend** declaration designates a (possibly cv-qualified) class type, that class is declared as a friend; otherwise, the friend declaration is ignored. [Example:

```

class C;
typedef C Ct;

class X1 {
    friend C; // OK: class C is a friend
};

class X2 {
    friend Ct; // OK: class C is a friend
};

```

```

friend D;                                // error: no type-name D in scope
friend class D;                          // OK: elaborated-type-specifier declares new class
};

template <typename T> class R {
    friend T;
};

R<C> rc;                                // class C is a friend of R<C>
R<int> Ri;                               // OK: "friend int;" is ignored
— end example]

```

- <sup>4</sup> A function first declared in a friend declaration has the linkage of the namespace of which it is a member (??). Otherwise, the function retains its previous linkage (??).
- <sup>5</sup> When a friend declaration refers to an overloaded name or operator, only the function specified by the parameter types becomes a friend. A member function of a class X can be a friend of a class Y. [Example:

```

class Y {
    friend char* X::foo(int);           // constructors can be friends
    friend X::X(char);                // destructors can be friends
    friend X::~X();                  // friends can be friends
};
— end example]

```

- <sup>6</sup> A function can be defined in a friend declaration of a class if and only if the class is a non-local class (??), the function name is unqualified, and the function has namespace scope. [Example:

```

class M {
    friend void f() { }               // definition of global f, a friend of M,
                                      // not the definition of a member function
};
— end example]

```

- <sup>7</sup> Such a function is implicitly an inline function (??). A friend function defined in a class is in the (lexical) scope of the class in which it is defined. A friend function defined outside the class is not (??).
- <sup>8</sup> No *storage-class-specifier* shall appear in the *decl-specifier-seq* of a friend declaration.
- <sup>9</sup> A name nominated by a friend declaration shall be accessible in the scope of the class containing the friend declaration. The meaning of the friend declaration is the same whether the friend declaration appears in the private, protected, or public (??) portion of the class *member-specification*.
- <sup>10</sup> Friendship is neither inherited nor transitive. [Example:

```

class A {
    friend class B;
    int a;
};

class B {
    friend class C;
};

```

```

class C {
    void f(A* p) {
        p->a++;
        // error: C is not a friend of A despite being a friend of a friend
    }
};

class D : public B {
    void f(A* p) {
        p->a++;
        // error: D is not a friend of A despite being derived from a friend
    }
};

— end example]

```

- <sup>11</sup> If a friend declaration appears in a local class (??) and the name specified is an unqualified name, a prior declaration is looked up without considering scopes that are outside the innermost enclosing non-class scope. For a friend function declaration, if there is no prior declaration, the program is ill-formed. For a friend class declaration, if there is no prior declaration, the class that is specified belongs to the innermost enclosing non-class scope, but if it is subsequently referenced, its name is not found by name lookup until a matching declaration is provided in the innermost enclosing non-class scope. [Example:

```

class X;
void a();
void f() {
    class Y;
    extern void b();
    class A {
        friend class X; // OK, but X is a local class, not ::X
        friend class Y; // OK
        friend class Z; // OK, introduces local class Z
        friend void a(); // error, ::a is not considered
        friend void b(); // OK
        friend void c(); // error
    };
    X* px; // OK, but ::X is found
    Z* pz; // error, no Z is found
}

```

— end example]

#### 14.4 Protected member access

[class.protected]

- <sup>1</sup> An additional access check beyond those described earlier in ?? is applied when a non-static data member or non-static member function is a protected member of its naming class (??).<sup>116</sup> As described earlier, access to a protected member is granted because the reference occurs in a friend or member of some class C. If the access is to form a pointer to member (??), the *nested-name-specifier* shall denote C or a class derived from C. All other accesses involve a (possibly implicit) object expression (??). In this case, the class of the object expression shall be C or a class derived from C. [Example:

---

<sup>116</sup> This additional check does not apply to other members, e.g., static data members or enumerator member constants.

```

class B {
protected:
    int i;
    static int j;
};

class D1 : public B {
};

class D2 : public B {
    friend void fr(B*,D1*,D2*);
    void mem(B*,D1*);
};

void fr(B* pb, D1* p1, D2* p2) {
    pb->i = 1;                                // ill-formed
    p1->i = 2;                                // ill-formed
    p2->i = 3;                                // OK (access through a D2)
    p2->B::i = 4;                            // OK (access through a D2, even though naming class is B)
    int B::* pmi_B = &B::i;                    // ill-formed
    int B::* pmi_B2 = &D2::i;                  // OK (type of &D2::i is int B::*)
    B::j = 5;                                 // ill-formed (not a friend of naming class B)
    D2::j = 6;                                // OK (because refers to static member)
}

void D2::mem(B* pb, D1* p1) {
    pb->i = 1;                                // ill-formed
    p1->i = 2;                                // ill-formed
    i = 3;                                    // OK (access through this)
    B::i = 4;                                // OK (access through this, qualification ignored)
    int B::* pmi_B = &B::i;                    // ill-formed
    int B::* pmi_B2 = &D2::i;                  // OK
    j = 5;                                    // OK (because j refers to static member)
    B::j = 6;                                // OK (because B::j refers to static member)
}

void g(B* pb, D1* p1, D2* p2) {
    pb->i = 1;                                // ill-formed
    p1->i = 2;                                // ill-formed
    p2->i = 3;                                // ill-formed
}

— end example ]

```

## 14.5 Access to virtual functions

[class.access.virt]

<sup>1</sup> The access rules (??) for a virtual function are determined by its declaration and are not affected by the rules for a function that later overrides it. [ *Example:*

```

class B {
public:
    virtual int f();

```

```

};

class D : public B {
private:
    int f();
};

void f() {
    D d;
    B* pb = &d;
    D* pd = &d;

    pb->f();           // OK: B::f() is public, D::f() is invoked
    pd->f();           // error: D::f() is private
}
— end example]

```

- <sup>2</sup> Access is checked at the call point using the type of the expression used to denote the object for which the member function is called (B\* in the example above). The access of the member function in the class in which it was defined (D in the example above) is in general not known.

## 14.6 Multiple access

[class.paths]

- <sup>1</sup> If a name can be reached by several paths through a multiple inheritance graph, the access is that of the path that gives most access. [Example:

```

class W { public: void f(); };
class A : private virtual W {};
class B : public virtual W {};
class C : public A, public B {
    void f() { W::f(); }           // OK
};

```

Since W::f() is available to C::f() along the public path through B, access is allowed. — end example]

## 14.7 Nested classes

[class.access.nest]

- <sup>1</sup> A nested class is a member and as such has the same access rights as any other member. The members of an enclosing class have no special access to members of a nested class; the usual access rules (??) shall be obeyed. [Example:

```

class E {
    int x;
    class B {};
}

class I {
    B b;                  // OK: E::I can access E::B
    int y;
    void f(E* p, int i) {
        p->x = i;          // OK: E::I can access E::x
    }
};

```

```
int g(I* p) {
    return p->y;           // error: I::y is private
}
};

— end example ]
```

# 15 Special member functions [special]

- <sup>1</sup> The default constructor (??), copy constructor and copy assignment operator (??), move constructor and move assignment operator (??), and destructor (??) are *special member functions*. [ *Note*: The implementation will implicitly declare these member functions for some class types when the program does not explicitly declare them. The implementation will implicitly define them if they are odr-used (??) or needed for constant evaluation (??). See ??, ?? and ??-. — *end note*] An implicitly-declared special member function is declared at the closing } of the *class-specifier*. Programs shall not define implicitly-declared special member functions.
- <sup>2</sup> Programs may explicitly refer to implicitly-declared special member functions. [ *Example*: A program may explicitly call, take the address of, or form a pointer to member to an implicitly-declared special member function.

```

struct A { };                                // implicitly declared A::operator=
struct B : A {
    B& operator=(const B &);
};
B& B::operator=(const B& s) {
    this->A::operator=(s);                  // well-formed
    return *this;
}

```

— *end example* ]

- <sup>3</sup> [ *Note*: The special member functions affect the way objects of class type are created, copied, moved, and destroyed, and how values can be converted to values of other types. Often such special member functions are called implicitly. — *end note* ]
- <sup>4</sup> Special member functions obey the usual access rules (??). [ *Example*: Declaring a constructor protected ensures that only derived classes and friends can create objects using it. — *end example* ]
- <sup>5</sup> For a class, its non-static data members, its non-virtual direct base classes, and, if the class is not abstract (??), its virtual base classes are called its *potentially constructed subobjects*.

## 15.1 Constructors

[class.ctor]

- <sup>1</sup> Constructors do not have names. In a declaration of a constructor, the *declarator* is a function declarator (??) of the form

*ptr-declarator ( parameter-declaration-clause ) noexcept-specifier<sub>opt</sub> attribute-specifier-seq<sub>opt</sub>*

where the *ptr-declarator* consists solely of an *id-expression*, an optional *attribute-specifier-seq*, and optional surrounding parentheses, and the *id-expression* has one of the following forms:

- (1.1) — in a *member-declaration* that belongs to the *member-specification* of a class but is not a friend declaration (??), the *id-expression* is the injected-class-name (??) of the immediately-enclosing class;
- (1.2) — in a *member-declaration* that belongs to the *member-specification* of a class template but is not a friend declaration, the *id-expression* is a *class-name* that names the current instantiation (??) of the immediately-enclosing class template; or

- (1.3) — in a declaration at namespace scope or in a friend declaration, the *id-expression* is a *qualified-id* that names a constructor (??).

The *class-name* shall not be a *typedef-name*. In a constructor declaration, each *decl-specifier* in the optional *decl-specifier-seq* shall be **friend**, **inline**, **explicit**, or **constexpr**. [ *Example*:

```
struct S {
    S();           // declares the constructor
};

S::S() {}        // defines the constructor
— end example ]
```

- 2 A constructor is used to initialize objects of its class type. Because constructors do not have names, they are never found during name lookup; however an explicit type conversion using the functional notation (??) will cause a constructor to be called to initialize an object. [ *Note*: For initialization of objects of class type see ???. — *end note* ]
- 3 A constructor can be invoked for a **const**, **volatile** or **const volatile** object. **const** and **volatile** semantics (??) are not applied on an object under construction. They come into effect when the constructor for the most derived object (??) ends.
- 4 A *default* constructor for a class **X** is a constructor of class **X** for which each parameter that is not a function parameter pack has a default argument (including the case of a constructor with no parameters). If there is no user-declared constructor for class **X**, a non-explicit constructor having no parameters is implicitly declared as defaulted (??). An implicitly-declared default constructor is an **inline** **public** member of its class.
- 5 A defaulted default constructor for class **X** is defined as deleted if:

- (5.1) — **X** is a union that has a variant member with a non-trivial default constructor and no variant member of **X** has a default member initializer,
- (5.2) — **X** is a non-union class that has a variant member **M** with a non-trivial default constructor and no variant member of the anonymous union containing **M** has a default member initializer,
- (5.3) — any non-static data member with no default member initializer (??) is of reference type,
- (5.4) — any non-variant non-static data member of const-qualified type (or array thereof) with no *brace-or-equal-initializer* does not have a user-provided default constructor,
- (5.5) — **X** is a union and all of its variant members are of const-qualified type (or array thereof),
- (5.6) — **X** is a non-union class and all members of any anonymous union member are of const-qualified type (or array thereof),
- (5.7) — any potentially constructed subobject, except for a non-static data member with a *brace-or-equal-initializer*, has class type **M** (or array thereof) and either **M** has no default constructor or overload resolution (??) as applied to find **M**'s corresponding constructor results in an ambiguity or in a function that is deleted or inaccessible from the defaulted default constructor, or
- (5.8) — any potentially constructed subobject has a type with a destructor that is deleted or inaccessible from the defaulted default constructor.

- 6 A default constructor is *trivial* if it is not user-provided and if:

- (6.1) — its class has no virtual functions (??) and no virtual base classes (??), and
- (6.2) — no non-static data member of its class has a default member initializer (??), and

- (6.3) — all the direct base classes of its class have trivial default constructors, and
- (6.4) — for all the non-static data members of its class that are of class type (or array thereof), each such class has a trivial default constructor.

Otherwise, the default constructor is *non-trivial*.

- 7 A default constructor that is defaulted and not defined as deleted is *implicitly defined* when it is odr-used (??) to create an object of its class type (??), when it is needed for constant evaluation (??), or when it is explicitly defaulted after its first declaration. The implicitly-defined default constructor performs the set of initializations of the class that would be performed by a user-written default constructor for that class with no *ctor-initializer* (??) and an empty *compound-statement*. If that user-written default constructor would be ill-formed, the program is ill-formed. If that user-written default constructor would satisfy the requirements of a *constexpr* constructor (??), the implicitly-defined default constructor is *constexpr*. Before the defaulted default constructor for a class is implicitly defined, all the non-user-provided default constructors for its base classes and its non-static data members shall have been implicitly defined. [ *Note*: An implicitly-declared default constructor has an exception specification (??). An explicitly-defaulted definition might have an implicit exception specification, see ?? . — *end note* ]
- 8 Default constructors are called implicitly to create class objects of static, thread, or automatic storage duration (??, ??, ??) defined without an initializer (??), are called to create class objects of dynamic storage duration (??) created by a *new-expression* in which the *new-initializer* is omitted (??), or are called when the explicit type conversion syntax (??) is used. A program is ill-formed if the default constructor for an object is implicitly used and the constructor is not accessible (??).
- 9 [ *Note*: ?? describes the order in which constructors for base classes and non-static data members are called and describes how arguments can be specified for the calls to these constructors. — *end note* ]
- 10 A **return** statement in the body of a constructor shall not specify a return value. The address of a constructor shall not be taken.
- 11 A functional notation type conversion (??) can be used to create new objects of its type. [ *Note*: The syntax looks like an explicit call of the constructor. — *end note* ] [ *Example*:

```
complex zz = complex(1,2.3);
cprint( complex(7.8,1.2) );
— end example ]
```

- 12 An object created in this way is unnamed. [ *Note*: ?? describes the lifetime of temporary objects. — *end note* ] [ *Note*: Explicit constructor calls do not yield lvalues, see ?? . — *end note* ]
- 13 [ *Note*: Some language constructs have special semantics when used during construction; see ?? and ?? . — *end note* ]
- 14 During the construction of an object, if the value of the object or any of its subobjects is accessed through a glvalue that is not obtained, directly or indirectly, from the constructor's **this** pointer, the value of the object or subobject thus obtained is unspecified. [ *Example*:

```
struct C;
void no_opt(C*);

struct C {
    int c;
    C() : c(0) { no_opt(this); }
};
```

```

const C cobj;

void no_opt(C* cptr) {
    int i = cobj.c * 100;           // value of cobj.c is unspecified
    cptr->c = 1;
    cout << cobj.c * 100           // value of cobj.c is unspecified
        << '\n';
}

extern struct D d;
struct D {
    D(int a) : a(a), b(d.a) {}
    int a, b;
};
D d = D(1);                   // value of d.b is unspecified
— end example]

```

## 15.2 Temporary objects

[class.temporary]

- <sup>1</sup> Temporary objects are created

- (1.1) — when a prvalue is materialized so that it can be used as a glvalue (??),
- (1.2) — when needed by the implementation to pass or return an object of trivially-copyable type (see below), and
- (1.3) — when throwing an exception (??). [Note: The lifetime of exception objects is described in ??.. — end note]

Even when the creation of the temporary object is unevaluated (??), all the semantic restrictions shall be respected as if the temporary object had been created and later destroyed. [Note: This includes accessibility (??) and whether it is deleted, for the constructor selected and for the destructor. However, in the special case of the operand of a *decltype-specifier* (??), no temporary is introduced, so the foregoing does not apply to such a prvalue. — end note]

- <sup>2</sup> The materialization of a temporary object is generally delayed as long as possible in order to avoid creating unnecessary temporary objects. [Note: Temporary objects are materialized:

- (2.1) — when binding a reference to a prvalue (??, ??, ??, ??, ??, ??),
- (2.2) — when performing member access on a class prvalue (??, ??),
- (2.3) — when performing an array-to-pointer conversion or subscripting on an array prvalue (??, ??),
- (2.4) — when initializing an object of type `std::initializer_list<T>` from a *braced-init-list* (??),
- (2.5) — for certain unevaluated operands (??, ??), and
- (2.6) — when a prvalue appears as a discarded-value expression (??).

— end note] [Example: Consider the following code:

```

class X {
public:
    X(int);
    X(const X&);
    X& operator=(const X&);

```

```

~X();
};

class Y {
public:
    Y(int);
    Y(Y&&);

    ~Y();
};

X f(X);
Y g(Y);

void h() {
    X a(1);
    X b = f(X(2));
    Y c = g(Y(3));
    a = f(a);
}

```

`X(2)` is constructed in the space used to hold `f()`'s argument and `Y(3)` is constructed in the space used to hold `g()`'s argument. Likewise, `f()`'s result is constructed directly in `b` and `g()`'s result is constructed directly in `c`. On the other hand, the expression `a = f(a)` requires a temporary for the result of `f(a)`, which is materialized so that the reference parameter of `A::operator=(const A&)` can bind to it. — *end example* ]

- <sup>3</sup> When an object of class type `X` is passed to or returned from a function, if each copy constructor, move constructor, and destructor of `X` is either trivial or deleted, and `X` has at least one non-deleted copy or move constructor, implementations are permitted to create a temporary object to hold the function parameter or result object. The temporary object is constructed from the function argument or return value, respectively, and the function's parameter or return object is initialized as if by using the non-deleted trivial constructor to copy the temporary (even if that constructor is inaccessible or would not be selected by overload resolution to perform a copy or move of the object). [ *Note:* This latitude is granted to allow objects of class type to be passed to or returned from functions in registers. — *end note* ]
- <sup>4</sup> When an implementation introduces a temporary object of a class that has a non-trivial constructor (??, ??), it shall ensure that a constructor is called for the temporary object. Similarly, the destructor shall be called for a temporary with a non-trivial destructor (??). Temporary objects are destroyed as the last step in evaluating the full-expression (??) that (lexically) contains the point where they were created. This is true even if that evaluation ends in throwing an exception. The value computations and side effects of destroying a temporary object are associated only with the full-expression, not with any specific subexpression.
- <sup>5</sup> There are three contexts in which temporaries are destroyed at a different point than the end of the full-expression. The first context is when a default constructor is called to initialize an element of an array with no corresponding initializer (??). The second context is when a copy constructor is called to copy an element of an array while the entire array is copied (??, ??). In either case, if the constructor has one or more default arguments, the destruction of every temporary created in a default argument is sequenced before the construction of the next array element, if any.
- <sup>6</sup> The third context is when a reference is bound to a temporary object.<sup>117</sup> The temporary object to which the

---

<sup>117</sup>) The same rules apply to initialization of an `initializer_list` object (??) with its underlying temporary array.

reference is bound or the temporary object that is the complete object of a subobject to which the reference is bound persists for the lifetime of the reference if the glvalue to which the reference is bound was obtained through one of the following:

- (6.1) — a temporary materialization conversion (??),
- (6.2) — ( *expression* ), where *expression* is one of these expressions,
- (6.3) — subscripting (??) of an array operand, where that operand is one of these expressions,
- (6.4) — a class member access (??) using the . operator where the left operand is one of these expressions and the right operand designates a non-static data member of non-reference type,
- (6.5) — a pointer-to-member operation (??) using the .\* operator where the left operand is one of these expressions and the right operand is a pointer to data member of non-reference type,
- (6.6) — a
  - (6.6.1) — `const_cast` (??),
  - (6.6.2) — `static_cast` (??),
  - (6.6.3) — `dynamic_cast` (??), or
  - (6.6.4) — `reinterpret_cast` (??)

converting, without a user-defined conversion, a glvalue operand that is one of these expressions to a glvalue that refers to the object designated by the operand, or to its complete object or a subobject thereof,

- (6.7) — a conditional expression (??) that is a glvalue where the second or third operand is one of these expressions, or
- (6.8) — a comma expression (??) that is a glvalue where the right operand is one of these expressions.

[ *Example*:

```
template<typename T> using id = T;

int&& a = id<int[3]>{1, 2, 3}[i];           // temporary array has same lifetime as a
const int& b = static_cast<const int&>(0); // temporary int has same lifetime as b
int&& c = cond ? id<int[3]>{1, 2, 3}[i] : static_cast<int&&>(0);
                                                // exactly one of the two temporaries is lifetime-extended
```

— end example] [ *Note*: An explicit type conversion (??, ??) is interpreted as a sequence of elementary casts, covered above. [ *Example*:

```
const int& x = (const int&)1; // temporary for value 1 has same lifetime as x
```

— end example] — end note] [ *Note*: If a temporary object has a reference member initialized by another temporary object, lifetime extension applies recursively to such a member's initializer. [ *Example*:

```
struct S {
    const int& m;
};

const S& s = S{1}; // both S and int temporaries have lifetime of s
```

— end example] — end note]

The exceptions to this lifetime rule are:

- (6.9) — A temporary object bound to a reference parameter in a function call (??) persists until the completion of the full-expression containing the call.
- (6.10) — The lifetime of a temporary bound to the returned value in a function return statement (??) is not extended; the temporary is destroyed at the end of the full-expression in the return statement.
- (6.11) — A temporary bound to a reference in a *new-initializer* (??) persists until the completion of the full-expression containing the *new-initializer*. [Note: This may introduce a dangling reference. —end note] [Example:

```
struct S { int mi; const std::pair<int,int>& mp; };
S a { 1, {2,3} };
S* p = new S{ 1, {2,3} };      // creates dangling reference
— end example]
```

- <sup>7</sup> The destruction of a temporary whose lifetime is not extended by being bound to a reference is sequenced before the destruction of every temporary which is constructed earlier in the same full-expression. If the lifetime of two or more temporaries to which references are bound ends at the same point, these temporaries are destroyed at that point in the reverse order of the completion of their construction. In addition, the destruction of temporaries bound to references shall take into account the ordering of destruction of objects with static, thread, or automatic storage duration (??, ??, ??); that is, if `obj1` is an object with the same storage duration as the temporary and created before the temporary is created the temporary shall be destroyed before `obj1` is destroyed; if `obj2` is an object with the same storage duration as the temporary and created after the temporary is created the temporary shall be destroyed after `obj2` is destroyed.

- <sup>8</sup> [Example:

```
struct S {
    S();
    S(int);
    friend S operator+(const S&, const S&);
    ~S();
};

S obj1;
const S& cr = S(16)+S(23);
S obj2;
```

the expression `S(16) + S(23)` creates three temporaries: a first temporary `T1` to hold the result of the expression `S(16)`, a second temporary `T2` to hold the result of the expression `S(23)`, and a third temporary `T3` to hold the result of the addition of these two expressions. The temporary `T3` is then bound to the reference `cr`. It is unspecified whether `T1` or `T2` is created first. On an implementation where `T1` is created before `T2`, `T2` shall be destroyed before `T1`. The temporaries `T1` and `T2` are bound to the reference parameters of `operator+`; these temporaries are destroyed at the end of the full-expression containing the call to `operator+`. The temporary `T3` bound to the reference `cr` is destroyed at the end of `cr`'s lifetime, that is, at the end of the program. In addition, the order in which `T3` is destroyed takes into account the destruction order of other objects with static storage duration. That is, because `obj1` is constructed before `T3`, and `T3` is constructed before `obj2`, `obj2` shall be destroyed before `T3`, and `T3` shall be destroyed before `obj1`. — end example]

### 15.3 Conversions

[class.conv]

- <sup>1</sup> Type conversions of class objects can be specified by constructors and by conversion functions. These conversions are called *user-defined conversions* and are used for implicit type conversions (??), for initialization

(??), and for explicit type conversions (??, ??).

- 2 User-defined conversions are applied only where they are unambiguous (??, ??). Conversions obey the access control rules (??). Access control is applied after ambiguity resolution (??).
- 3 [ *Note*: See ?? for a discussion of the use of conversions in function calls as well as examples below. — *end note* ]
- 4 At most one user-defined conversion (constructor or conversion function) is implicitly applied to a single value. [ *Example*:

```
struct X {
    operator int();
};

struct Y {
    operator X();
};

Y a;
int b = a;           // error, a.operator X().operator int() not tried
int c = X(a);       // OK: a.operator X().operator int()

— end example ]
```

- 5 User-defined conversions are used implicitly only if they are unambiguous. A conversion function in a derived class does not hide a conversion function in a base class unless the two functions convert to the same type. Function overload resolution (??) selects the best conversion function to perform the conversion. [ *Example*:

```
struct X {
    operator int();
};

struct Y : X {
    operator char();
};

void f(Y& a) {
    if (a) {           // ill-formed: X::operator int() or Y::operator char()
    }
}

— end example ]
```

### 15.3.1 Conversion by constructor

[class.conv.ctor]

- 1 A constructor declared without the *function-specifier* `explicit` specifies a conversion from the types of its parameters (if any) to the type of its class. Such a constructor is called a *converting constructor*. [ *Example*:

```
struct X {
    X(int);
    X(const char*, int =0);
    X(int, int);
};
```

```

void f(X arg) {
    X a = 1;           // a = X(1)
    X b = "Jessie";   // b = X("Jessie",0)
    a = 2;           // a = X(2)
    f(3);           // f(X(3))
    f({1, 2});       // f(X(1,2))
}

```

— end example ]

- <sup>2</sup> [ *Note*: An explicit constructor constructs objects just like non-explicit constructors, but does so only where the direct-initialization syntax (??) or where casts (??, ??) are explicitly used; see also ???. A default constructor may be an explicit constructor; such a constructor will be used to perform default-initialization or value-initialization (??). [ *Example*:

```

struct Z {
    explicit Z();
    explicit Z(int);
    explicit Z(int, int);
};

Z a;                                // OK: default-initialization performed
Z b{};                               // OK: direct initialization syntax used
Z c = {};;                           // error: copy-list-initialization
Z a1 = 1;                            // error: no implicit conversion
Z a3 = Z(1);                          // OK: direct initialization syntax used
Z a2(1);                            // OK: direct initialization syntax used
Z* p = new Z(1);                     // OK: direct initialization syntax used
Z a4 = (Z)1;                           // OK: explicit cast used
Z a5 = static_cast<Z>(1);           // OK: explicit cast used
Z a6 = { 3, 4 };                      // error: no implicit conversion

```

— end example ] — end note ]

- <sup>3</sup> A non-explicit copy/move constructor (??) is a converting constructor. [ *Note*: An implicitly-declared copy/move constructor is not an explicit constructor; it may be called for implicit type conversions. — end note ]

### 15.3.2 Conversion functions

[class.conv.fct]

- <sup>1</sup> A member function of a class X having no parameters with a name of the form

```

conversion-function-id:
operator conversion-type-id

conversion-type-id:
type-specifier-seq conversion-declaratoropt

conversion-declarator:
ptr-operator conversion-declaratoropt

```

specifies a conversion from X to the type specified by the *conversion-type-id*. Such functions are called *conversion functions*. A *decl-specifier* in the *decl-specifier-seq* of a conversion function (if any) shall be neither a *defining-type-specifier* nor **static**. The type of the conversion function (??) is “function taking no parameter returning *conversion-type-id*”. A conversion function is never used to convert a (possibly cv-qualified) object

to the (possibly cv-qualified) same object type (or a reference to it), to a (possibly cv-qualified) base class of that type (or a reference to it), or to (possibly cv-qualified) void.<sup>118</sup> [Example:

```
struct X {
    operator int();
    operator auto() -> short;      // error: trailing return type
};

void f(X a) {
    int i = int(a);
    i = (int)a;
    i = a;
}
```

In all three cases the value assigned will be converted by `X::operator int()`. —end example]

- <sup>2</sup> A conversion function may be explicit (??), in which case it is only considered as a user-defined conversion for direct-initialization (??). Otherwise, user-defined conversions are not restricted to use in assignments and initializations. [Example:

```
class Y {};
struct Z {
    explicit operator Y() const;
};

void h(Z z) {
    Y y1(z);           // OK: direct-initialization
    Y y2 = z;          // ill-formed: copy-initialization
    Y y3 = (Y)z;       // OK: cast notation
}

void g(X a, X b) {
    int i = (a) ? 1+a : 0;
    int j = (a&&b) ? a+b : i;
    if (a) {
    }
}
```

—end example]

- <sup>3</sup> The *conversion-type-id* shall not represent a function type nor an array type. The *conversion-type-id* in a *conversion-function-id* is the longest sequence of tokens that could possibly form a *conversion-type-id*. [Note: This prevents ambiguities between the declarator operator \* and its expression counterparts. [Example:

```
&ac.operator int*i; // syntax error:
                     // parsed as: &(ac.operator int *)i
                     // not as: &(ac.operator int)*i
```

The \* is the pointer declarator and not the multiplication operator. —end example] This rule also prevents ambiguities for attributes. [Example:

```
operator int [[noreturn]] (); // error: noreturn attribute applied to a type
```

<sup>118</sup>) These conversions are considered as standard conversions for the purposes of overload resolution (??, ??) and therefore initialization (??) and explicit casts (??). A conversion to void does not invoke any conversion function (??). Even though never directly called to perform a conversion, such conversion functions can be declared and can potentially be reached through a call to a virtual conversion function in a base class.

— end example] — end note]

- 4 Conversion functions are inherited.
- 5 Conversion functions can be virtual.
- 6 A conversion function template shall not have a deduced return type (??). [Example:

```
struct S {
    operator auto() const { return 10; }           // OK
    template<class T>
    operator auto() const { return 1.2; }          // error: conversion function template
};

— end example]
```

## 15.4    Destructors

[class.dtor]

- 1 In a declaration of a destructor, the *declarator* is a function declarator (??) of the form

*ptr-declarator* ( *parameter-declaration-clause* ) *noexcept-specifier<sub>opt</sub>* *attribute-specifier-seq<sub>opt</sub>*

where the *ptr-declarator* consists solely of an *id-expression*, an optional *attribute-specifier-seq*, and optional surrounding parentheses, and the *id-expression* has one of the following forms:

- (1.1) — in a *member-declaration* that belongs to the *member-specification* of a class but is not a friend declaration (??), the *id-expression* is  $\sim$  *class-name* and the *class-name* is the injected-class-name (??) of the immediately-enclosing class;
- (1.2) — in a *member-declaration* that belongs to the *member-specification* of a class template but is not a friend declaration, the *id-expression* is  $\sim$  *class-name* and the *class-name* names the current instantiation (??) of the immediately-enclosing class template; or
- (1.3) — in a declaration at namespace scope or in a friend declaration, the *id-expression* is *nested-name-specifier*  $\sim$  *class-name* and the *class-name* names the same class as the *nested-name-specifier*.

The *class-name* shall not be a *typedef-name*. A destructor shall take no arguments (??). Each *decl-specifier* of the *decl-specifier-seq* of a destructor declaration (if any) shall be **friend**, **inline**, or **virtual**.

- 2 A destructor is used to destroy objects of its class type. The address of a destructor shall not be taken. A destructor can be invoked for a **const**, **volatile** or **const volatile** object. **const** and **volatile** semantics (??) are not applied on an object under destruction. They stop being in effect when the destructor for the most derived object (??) starts.
- 3 [Note: A declaration of a destructor that does not have a *noexcept-specifier* has the same exception specification as if had been implicitly declared (??). — end note]
- 4 If a class has no user-declared destructor, a destructor is implicitly declared as defaulted (??). An implicitly-declared destructor is an inline public member of its class.
- 5 A defaulted destructor for a class **X** is defined as deleted if:
  - (5.1) — **X** is a union-like class that has a variant member with a non-trivial destructor,
  - (5.2) — any potentially constructed subobject has class type **M** (or array thereof) and **M** has a deleted destructor or a destructor that is inaccessible from the defaulted destructor,
  - (5.3) — or, for a virtual destructor, lookup of the non-array deallocation function results in an ambiguity or in a function that is deleted or inaccessible from the defaulted destructor.
- 6 A destructor is trivial if it is not user-provided and if:

- (6.1) — the destructor is not **virtual**,
- (6.2) — all of the direct base classes of its class have trivial destructors, and
- (6.3) — for all of the non-static data members of its class that are of class type (or array thereof), each such class has a trivial destructor.

Otherwise, the destructor is *non-trivial*.

- <sup>7</sup> A destructor that is defaulted and not defined as deleted is *implicitly defined* when it is odr-used (??) or when it is explicitly defaulted after its first declaration.
- <sup>8</sup> Before the defaulted destructor for a class is implicitly defined, all the non-user-provided destructors for its base classes and its non-static data members shall have been implicitly defined.
- <sup>9</sup> After executing the body of the destructor and destroying any automatic objects allocated within the body, a destructor for class X calls the destructors for X's direct non-variant non-static data members, the destructors for X's non-virtual direct base classes and, if X is the type of the most derived class (??), its destructor calls the destructors for X's virtual base classes. All destructors are called as if they were referenced with a qualified name, that is, ignoring any possible virtual overriding destructors in more derived classes. Bases and members are destroyed in the reverse order of the completion of their constructor (see ??). A **return** statement (??) in a destructor might not directly return to the caller; before transferring control to the caller, the destructors for the members and bases are called. Destructors for elements of an array are called in reverse order of their construction (see ??).
- <sup>10</sup> A destructor can be declared **virtual** (??) or pure **virtual** (??); if any objects of that class or any derived class are created in the program, the destructor shall be defined. If a class has a base class with a virtual destructor, its destructor (whether user- or implicitly-declared) is virtual.

<sup>11</sup> [ *Note*: Some language constructs have special semantics when used during destruction; see ?? . — *end note* ]

<sup>12</sup> A destructor is invoked implicitly

- (12.1) — for a constructed object with static storage duration (??) at program termination (??),
- (12.2) — for a constructed object with thread storage duration (??) at thread exit,
- (12.3) — for a constructed object with automatic storage duration (??) when the block in which an object is created exits (??),
- (12.4) — for a constructed temporary object when its lifetime ends (??, ??).

In each case, the context of the invocation is the context of the construction of the object. A destructor is also invoked implicitly through use of a *delete-expression* (??) for a constructed object allocated by a *new-expression* (??); the context of the invocation is the *delete-expression*. [ *Note*: An array of class type contains several subobjects for each of which the destructor is invoked. — *end note* ] A destructor can also be invoked explicitly. A destructor is *potentially invoked* if it is invoked or as specified in ??, ??, and ?? . A program is ill-formed if a destructor that is potentially invoked is deleted or not accessible from the context of the invocation.

- <sup>13</sup> At the point of definition of a virtual destructor (including an implicit definition (??)), the non-array deallocation function is determined as if for the expression **delete this** appearing in a non-virtual destructor of the destructor's class (see ??). If the lookup fails or if the deallocation function has a deleted definition (??), the program is ill-formed. [ *Note*: This assures that a deallocation function corresponding to the dynamic type of an object is available for the *delete-expression* (??). — *end note* ]

- <sup>14</sup> In an explicit destructor call, the destructor is specified by a `~` followed by a *type-name* or *decltype-specifier* that denotes the destructor's class type. The invocation of a destructor is subject to the usual rules for member functions (??); that is, if the object is not of the destructor's class type and not of a class derived from the destructor's class type (including when the destructor is invoked via a null pointer value), the program has undefined behavior. [ *Note:* Invoking `delete` on a null pointer does not call the destructor; see ??-. — *end note*] [ *Example:*

```

struct B {
    virtual ~B() { }
};

struct D : B {
    ~D() { }
};

D D_object;
typedef B B_alias;
B* B_ptr = &D_object;

void f() {
    D_object.B::~B();           // calls B's destructor
    B_ptr->~B();              // calls D's destructor
    B_ptr->~B_alias();        // calls D's destructor
    B_ptr->B_alias::~B();     // calls B's destructor
    B_ptr->B_alias::~B_alias(); // calls B's destructor
}

```

— *end example*] [ *Note:* An explicit destructor call must always be written using a member access operator (??) or a *qualified-id* (??); in particular, the *unary-expression* `~X()` in a member function is not an explicit destructor call (??). — *end note*]

- <sup>15</sup> [ *Note:* Explicit calls of destructors are rarely needed. One use of such calls is for objects placed at specific addresses using a placement *new-expression*. Such use of explicit placement and destruction of objects can be necessary to cope with dedicated hardware resources and for writing memory management facilities. For example,

```

void* operator new(std::size_t, void* p) { return p; }

struct X {
    X(int);
    ~X();
};

void f(X* p);

void g() {                                     // rare, specialized use:
    char* buf = new char[sizeof(X)];
    X* p = new(buf) X(222);                  // use buf[] and initialize
    f(p);
    p->X::~X();                            // cleanup
}

```

— *end note*]

- <sup>16</sup> Once a destructor is invoked for an object, the object no longer exists; the behavior is undefined if the destructor is invoked for an object whose lifetime has ended (??). [Example: If the destructor for an automatic object is explicitly invoked, and the block is subsequently left in a manner that would ordinarily invoke implicit destruction of the object, the behavior is undefined. —end example]
- <sup>17</sup> [Note: The notation for explicit call of a destructor can be used for any scalar type name (??). Allowing this makes it possible to write code without having to know if a destructor exists for a given type. For example:

```
typedef int I;
I* p;
p->I::~I();
```

—end note]

## 15.5 Free store

[class.free]

- <sup>1</sup> Any allocation function for a class T is a static member (even if not explicitly declared **static**).  
<sup>2</sup> [Example:

```
class Arena;
struct B {
    void* operator new(std::size_t, Arena*);
};
struct D1 : B {
};

Arena* ap;
void foo(int i) {
    new (ap) D1;      // calls B::operator new(std::size_t, Arena*)
    new D1[i];        // calls ::operator new[](std::size_t)
    new D1;            // ill-formed: ::operator new(std::size_t) hidden
}
```

—end example]

- <sup>3</sup> When an object is deleted with a *delete-expression* (??), a deallocation function (**operator delete()** for non-array objects or **operator delete[]()** for arrays) is (implicitly) called to reclaim the storage occupied by the object (??).
- <sup>4</sup> Class-specific deallocation function lookup is a part of general deallocation function lookup (??) and occurs as follows. If the *delete-expression* is used to deallocate a class object whose static type has a virtual destructor, the deallocation function is the one selected at the point of definition of the dynamic type's virtual destructor (??).<sup>119</sup> Otherwise, if the *delete-expression* is used to deallocate an object of class T or array thereof, the static and dynamic types of the object shall be identical and the deallocation function's name is looked up in the scope of T. If this lookup fails to find the name, general deallocation function lookup (??) continues. If the result of the lookup is ambiguous or inaccessible, or if the lookup selects a placement deallocation function, the program is ill-formed.
- <sup>5</sup> Any deallocation function for a class X is a static member (even if not explicitly declared **static**). [Example:

```
class X {
    void operator delete(void*);
```

<sup>119</sup>) A similar provision is not needed for the array version of **operator delete** because ?? requires that in this situation, the static type of the object to be deleted be the same as its dynamic type.

```

    void operator delete[](void*, std::size_t);
};

class Y {
    void operator delete(void*, std::size_t);
    void operator delete[](void*);
};

— end example ]

```

- <sup>6</sup> Since member allocation and deallocation functions are `static` they cannot be virtual. [ *Note:* However, when the *cast-expression* of a *delete-expression* refers to an object of class type, because the deallocation function actually called is looked up in the scope of the class that is the dynamic type of the object, if the destructor is virtual, the effect is the same. For example,

```

struct B {
    virtual ~B();
    void operator delete(void*, std::size_t);
};

struct D : B {
    void operator delete(void*);
};

void f() {
    B* bp = new D;
    delete bp;           // 1: uses D::operator delete(void*)
}

```

Here, storage for the non-array object of class D is deallocated by `D::operator delete()`, due to the virtual destructor. — *end note* ] [ *Note:* Virtual destructors have no effect on the deallocation function actually called when the *cast-expression* of a *delete-expression* refers to an array of objects of class type. For example,

```

struct B {
    virtual ~B();
    void operator delete[](void*, std::size_t);
};

struct D : B {
    void operator delete[](void*, std::size_t);
};

void f(int i) {
    D* dp = new D[i];
    delete [] dp;        // uses D::operator delete[](void*, std::size_t)
    B* bp = new D[i];
    delete[] bp;         // undefined behavior
}

— end note ]

```

- <sup>7</sup> Access to the deallocation function is checked statically. Hence, even though a different one might actually be executed, the statically visible deallocation function is required to be accessible. [ *Example:* For the call

on line “// 1” above, if `B::operator delete()` had been private, the delete expression would have been ill-formed. — end example]

- <sup>8</sup> [ Note: If a deallocation function has no explicit *noexcept-specifier*, it has a non-throwing exception specification (??). — end note]

## 15.6 Initialization

[class.init]

- <sup>1</sup> When no initializer is specified for an object of (possibly cv-qualified) class type (or array thereof), or the initializer has the form `()`, the object is initialized as specified in ??.
- <sup>2</sup> An object of class type (or array thereof) can be explicitly initialized; see ?? and ??.
- <sup>3</sup> When an array of class objects is initialized (either explicitly or implicitly) and the elements are initialized by constructor, the constructor shall be called for each element of the array, following the subscript order; see ???. [ Note: Destructors for the array elements are called in reverse order of their construction. — end note]

### 15.6.1 Explicit initialization

[class.expl.init]

- <sup>1</sup> An object of class type can be initialized with a parenthesized *expression-list*, where the *expression-list* is construed as an argument list for a constructor that is called to initialize the object. Alternatively, a single *assignment-expression* can be specified as an *initializer* using the = form of initialization. Either direct-initialization semantics or copy-initialization semantics apply; see ???. [ Example:

```
struct complex {
    complex();
    complex(double);
    complex(double,double);
};

complex sqrt(complex,complex);

complex a(1);           // initialize by a call of complex(double)
complex b = a;          // initialize by a copy of a
complex c = complex(1,2); // construct complex(1,2) using complex(double,double),
                        // copy/move it into c
complex d = sqrt(b,c); // call sqrt(complex,complex) and copy/move the result into d
complex e;              // initialize by a call of complex()
complex f = 3;          // construct complex(3) using complex(double), copy/move it into f
complex g = { 1, 2 };    // initialize by a call of complex(double, double)
```

— end example] [ Note: Overloading of the assignment operator (??) has no effect on initialization. — end note]

- <sup>2</sup> An object of class type can also be initialized by a *braced-init-list*. List-initialization semantics apply; see ?? and ???. [ Example:

```
complex v[6] = { 1, complex(1,2), complex(), 2 };
```

Here, `complex::complex(double)` is called for the initialization of `v[0]` and `v[3]`, `complex::complex(double, double)` is called for the initialization of `v[1]`, `complex::complex()` is called for the initialization `v[2]`, `v[4]`, and `v[5]`. For another example,

```
struct X {
    int i;
    float f;
```

```
complex c;
} x = { 99, 88.8, 77.7 };
```

Here, `x.i` is initialized with 99, `x.f` is initialized with 88.8, and `complex::complex(double)` is called for the initialization of `x.c`. — end example] [ Note: Braces can be elided in the *initializer-list* for any aggregate, even if the aggregate has members of a class type with user-defined type conversions; see ???. — end note]

- <sup>3</sup> [ Note: If `T` is a class type with no default constructor, any declaration of an object of type `T` (or array thereof) is ill-formed if no *initializer* is explicitly specified (see ?? and ??). — end note]
- <sup>4</sup> [ Note: The order in which objects with static or thread storage duration are initialized is described in ?? and ???. — end note]

### 15.6.2 Initializing bases and members

[class.base.init]

- <sup>1</sup> In the definition of a constructor for a class, initializers for direct and virtual base class subobjects and non-static data members can be specified by a *ctor-initializer*, which has the form

```
ctor-initializer:
  : mem-initializer-list

mem-initializer-list:
  mem-initializer ...opt
  mem-initializer-list , mem-initializer ...opt

mem-initializer:
  mem-initializer-id ( expression-listopt )
  mem-initializer-id braced-init-list

mem-initializer-id:
  class-or-decltype
  identifier
```

- <sup>2</sup> In a *mem-initializer-id* an initial unqualified *identifier* is looked up in the scope of the constructor's class and, if not found in that scope, it is looked up in the scope containing the constructor's definition. [ Note: If the constructor's class contains a member with the same name as a direct or virtual base class of the class, a *mem-initializer-id* naming the member or base class and composed of a single identifier refers to the class member. A *mem-initializer-id* for the hidden base class may be specified using a qualified name. — end note] Unless the *mem-initializer-id* names the constructor's class, a non-static data member of the constructor's class, or a direct or virtual base of that class, the *mem-initializer* is ill-formed.
- <sup>3</sup> A *mem-initializer-list* can initialize a base class using any *class-or-decltype* that denotes that base class type. [ Example:

```
struct A { A(); };
typedef A global_A;
struct B { };
struct C: public A, public B { C(); };
C::C(): global_A() {}           // mem-initializer for base A
— end example]
```

- <sup>4</sup> If a *mem-initializer-id* is ambiguous because it designates both a direct non-virtual base class and an inherited virtual base class, the *mem-initializer* is ill-formed. [ Example:

```
struct A { A(); };
struct B: public virtual A { };
struct C: public A, public B { C(); };
```

```
C::C(): A() { }           // ill-formed: which A?  
— end example ]
```

- 5 A *ctor-initializer* may initialize a variant member of the constructor's class. If a *ctor-initializer* specifies more than one *mem-initializer* for the same member or for the same base class, the *ctor-initializer* is ill-formed.
- 6 A *mem-initializer-list* can delegate to another constructor of the constructor's class using any *class-or-decltype* that denotes the constructor's class itself. If a *mem-initializer-id* designates the constructor's class, it shall be the only *mem-initializer*; the constructor is a *delegating constructor*, and the constructor selected by the *mem-initializer* is the *target constructor*. The target constructor is selected by overload resolution. Once the target constructor returns, the body of the delegating constructor is executed. If a constructor delegates to itself directly or indirectly, the program is ill-formed, no diagnostic required. [ *Example*:

```
struct C {  
    C( int ) { }           // #1: non-delegating constructor  
    C(): C(42) { }        // #2: delegates to #1  
    C( char c ) : C(42.0) { } // #3: ill-formed due to recursion with #4  
    C( double d ) : C('a') { } // #4: ill-formed due to recursion with #3  
};
```

— end example ]

- 7 The *expression-list* or *braced-init-list* in a *mem-initializer* is used to initialize the designated subobject (or, in the case of a delegating constructor, the complete class object) according to the initialization rules of ?? for direct-initialization. [ *Example*:

```
struct B1 { B1(int); /* ... */ };  
struct B2 { B2(int); /* ... */ };  
struct D : B1, B2 {  
    D(int);  
    B1 b;  
    const int c;  
};  
  
D::D(int a) : B2(a+1), B1(a+2), c(a+3), b(a+4) { /* ... */ }  
D d(10);
```

— end example ] [ *Note*: The initialization performed by each *mem-initializer* constitutes a full-expression (??). Any expression in a *mem-initializer* is evaluated as part of the full-expression that performs the initialization.  
— end note ] A *mem-initializer* where the *mem-initializer-id* denotes a virtual base class is ignored during execution of a constructor of any class that is not the most derived class.

- 8 A temporary expression bound to a reference member in a *mem-initializer* is ill-formed. [ *Example*:

```
struct A {  
    A() : v(42) { } // error  
    const int& v;  
};
```

— end example ]

- 9 In a non-delegating constructor, if a given potentially constructed subobject is not designated by a *mem-initializer-id* (including the case where there is no *mem-initializer-list* because the constructor has no *ctor-initializer*), then

- (9.1) — if the entity is a non-static data member that has a default member initializer (??) and either

- (9.1.1) — the constructor's class is a union (??), and no other variant member of that union is designated by a *mem-initializer-id* or
- (9.1.2) — the constructor's class is not a union, and, if the entity is a member of an anonymous union, no other member of that union is designated by a *mem-initializer-id*,  
the entity is initialized from its default member initializer as specified in ??;
- (9.2) — otherwise, if the entity is an anonymous union or a variant member (??), no initialization is performed;
- (9.3) — otherwise, the entity is default-initialized (??).

[*Note*: An abstract class (??) is never a most derived class, thus its constructors never initialize virtual base classes, therefore the corresponding *mem-initializers* may be omitted. — *end note*] An attempt to initialize more than one non-static data member of a union renders the program ill-formed. [ *Note*: After the call to a constructor for class X for an object with automatic or dynamic storage duration has completed, if the constructor was not invoked as part of value-initialization and a member of X is neither initialized nor given a value during execution of the *compound-statement* of the body of the constructor, the member has an indeterminate value. — *end note*] [*Example*:

```
struct A {
    A();
};

struct B {
    B(int);
};

struct C {
    C() { }           // initializes members as follows:
    A a;              // OK: calls A::A()
    const B b;         // error: B has no default constructor
    int i;             // OK: i has indeterminate value
    int j = 5;          // OK: j has the value 5
};

— end example]
```

- <sup>10</sup> If a given non-static data member has both a default member initializer and a *mem-initializer*, the initialization specified by the *mem-initializer* is performed, and the non-static data member's default member initializer is ignored. [*Example*: Given

```
struct A {
    int i = /* some integer expression with side effects */ ;
    A(int arg) : i(arg) { }
    // ...
};
```

the A(int) constructor will simply initialize i to the value of arg, and the side effects in i's default member initializer will not take place. — *end example*]

- <sup>11</sup> A temporary expression bound to a reference member from a default member initializer is ill-formed. [*Example*:

```
struct A {
    A() = default;      // OK
```

```

A(int v) : v(v) {} // OK
const int& v = 42; // OK
};

A a1; // error: ill-formed binding of temporary to reference
A a2(1); // OK, unfortunately

— end example]

```

- <sup>12</sup> In a non-delegating constructor, the destructor for each potentially constructed subobject of class type is potentially invoked (??). [Note: This provision ensures that destructors can be called for fully-constructed subobjects in case an exception is thrown (??). — end note]

- <sup>13</sup> In a non-delegating constructor, initialization proceeds in the following order:

- (13.1) — First, and only for the constructor of the most derived class (??), virtual base classes are initialized in the order they appear on a depth-first left-to-right traversal of the directed acyclic graph of base classes, where “left-to-right” is the order of appearance of the base classes in the derived class *base-specifier-list*.
- (13.2) — Then, direct base classes are initialized in declaration order as they appear in the *base-specifier-list* (regardless of the order of the *mem-initializers*).
- (13.3) — Then, non-static data members are initialized in the order they were declared in the class definition (again regardless of the order of the *mem-initializers*).
- (13.4) — Finally, the *compound-statement* of the constructor body is executed.

[Note: The declaration order is mandated to ensure that base and member subobjects are destroyed in the reverse order of initialization. — end note]

- <sup>14</sup> [Example:

```

struct V {
    V();
    V(int);
};

struct A : virtual V {
    A();
    A(int);
};

struct B : virtual V {
    B();
    B(int);
};

struct C : A, B, virtual V {
    C();
    C(int);
};

A::A(int i) : V(i) { /* ... */ }
B::B(int i) { /* ... */ }
C::C(int i) { /* ... */ }

```

```
V v(1);           // use V(int)
A a(2);           // use V(int)
B b(3);           // use V()
C c(4);           // use V()

— end example ]
```

- 15 Names in the *expression-list* or *braced-init-list* of a *mem-initializer* are evaluated in the scope of the constructor for which the *mem-initializer* is specified. [ *Example*:

```
class X {
    int a;
    int b;
    int i;
    int j;
public:
    const int& r;
    X(int i): r(a), b(i), i(i), j(this->i) { }
};
```

initializes `X::r` to refer to `X::a`, initializes `X::b` with the value of the constructor parameter `i`, initializes `X::i` with the value of the constructor parameter `i`, and initializes `X::j` with the value of `X::i`; this takes place each time an object of class `X` is created. — *end example*] [ *Note*: Because the *mem-initializer* are evaluated in the scope of the constructor, the `this` pointer can be used in the *expression-list* of a *mem-initializer* to refer to the object being initialized. — *end note*]

- 16 Member functions (including virtual member functions, ??) can be called for an object under construction. Similarly, an object under construction can be the operand of the `typeid` operator (??) or of a `dynamic_cast` (??). However, if these operations are performed in a *ctor-initializer* (or in a function called directly or indirectly from a *ctor-initializer*) before all the *mem-initializers* for base classes have completed, the program has undefined behavior. [ *Example*:

```
class A {
public:
    A(int);
};

class B : public A {
    int j;
public:
    int f();
    B() : A(f()),      // undefined: calls member function but base A not yet initialized
          j(f()) { }      // well-defined: bases are all initialized
};

class C {
public:
    C(int);
};

class D : public B, C {
    int i;
```

```

public:
    D() : C(f()),      // undefined: calls member function but base C not yet initialized
          i(f()) { }   // well-defined: bases are all initialized
};

— end example]

```

- 17 [Note: ?? describes the result of virtual function calls, typeid and dynamic\_casts during construction for the well-defined cases; that is, describes the *polymorphic behavior* of an object under construction. — end note]

- 18 A *mem-initializer* followed by an ellipsis is a pack expansion (??) that initializes the base classes specified by a pack expansion in the *base-specifier-list* for the class. [Example:

```

template<class... Mixins>
class X : public Mixins... {
public:
    X(const Mixins&... mixins) : Mixins(mixins)... { }
};

— end example]

```

### 15.6.3 Initialization by inherited constructor

[class.inhctor.init]

- <sup>1</sup> When a constructor for type B is invoked to initialize an object of a different type D (that is, when the constructor was inherited (??)), initialization proceeds as if a defaulted default constructor were used to initialize the D object and each base class subobject from which the constructor was inherited, except that the B subobject is initialized by the invocation of the inherited constructor. The complete initialization is considered to be a single function call; in particular, the initialization of the inherited constructor's parameters is sequenced before the initialization of any part of the D object. [Example:

```

struct B1 {
    B1(int, ...) { }
};

struct B2 {
    B2(double) { }
};

int get();

struct D1 : B1 {
    using B1::B1;      // inherits B1(int, ...)
    int x;
    int y = get();
};

void test() {
    D1 d(2, 3, 4);   // OK: B1 is initialized by calling B1(2, 3, 4),
                      // then d.x is default-initialized (no initialization is performed),
                      // then d.y is initialized by calling get()
    D1 e;             // error: D1 has a deleted default constructor
}

```

```

struct D2 : B2 {
    using B2::B2;
    B1 b;
};

D2 f(1.0);           // error: B1 has a deleted default constructor

struct W { W(int); };
struct X : virtual W { using W::W; X() = delete; };
struct Y : X { using X::X; };
struct Z : Y, virtual W { using Y::Y; };
Z z(0);           // OK: initialization of Y does not invoke default constructor of X

template<class T> struct Log : T {
    using T::T;           // inherits all constructors from class T
    ~Log() { std::clog << "Destroying wrapper" << std::endl; }
};

```

Class template Log wraps any class and forwards all of its constructors, while writing a message to the standard log whenever an object of class Log is destroyed. — end example]

- 2 If the constructor was inherited from multiple base class subobjects of type B, the program is ill-formed.  
[Example:

```

struct A { A(int); };
struct B : A { using A::A; };

struct C1 : B { using B::B; };
struct C2 : B { using B::B; };

struct D1 : C1, C2 {
    using C1::C1;
    using C2::C2;
};

struct V1 : virtual B { using B::B; };
struct V2 : virtual B { using B::B; };

struct D2 : V1, V2 {
    using V1::V1;
    using V2::V2;
};

D1 d1(0);           // ill-formed: ambiguous
D2 d2(0);           // OK: initializes virtual B base class, which initializes the A base class
                      // then initializes the V1 and V2 base classes as if by a defaulted default constructor

struct M { M(); M(int); };
struct N : M { using M::M; };
struct O : M {};
struct P : N, O { using N::N; using O::O; };

```

```
P p(0);           // OK: use M(0) to initialize N's base class,
                  // use M() to initialize O's base class
— end example]
```

- 3 When an object is initialized by an inherited constructor, initialization of the object is complete when the initialization of all subobjects is complete.

## 15.7 Construction and destruction

[class.cdtor]

- <sup>1</sup> For an object with a non-trivial constructor, referring to any non-static member or base class of the object before the constructor begins execution results in undefined behavior. For an object with a non-trivial destructor, referring to any non-static member or base class of the object after the destructor finishes execution results in undefined behavior. [ *Example*:

```
struct X { int i; };
struct Y : X { Y(); };           // non-trivial
struct A { int a; };
struct B : public A { int j; Y y; }; // non-trivial

extern B bobj;
B* pb = &bobj;                 // OK
int* p1 = &bobj.a;             // undefined, refers to base class member
int* p2 = &bobj.y.i;            // undefined, refers to member's member

A* pa = &bobj;                 // undefined, upcast to a base class type
B bobj;                         // definition of bobj

extern X xobj;
int* p3 = &xobj.i;              // OK, X is a trivial class
X xobj;
```

For another example,

```
struct W { int j; };
struct X : public virtual W {};
struct Y {
    int* p;
    X x;
    Y() : p(&x.j) {} // undefined, x is not yet constructed
};
};
```

— end example]

- 2 To explicitly or implicitly convert a pointer (a glvalue) referring to an object of class X to a pointer (reference) to a direct or indirect base class B of X, the construction of X and the construction of all of its direct or indirect bases that directly or indirectly derive from B shall have started and the destruction of these classes shall not have completed, otherwise the conversion results in undefined behavior. To form a pointer to (or access the value of) a direct non-static member of an object obj, the construction of obj shall have started and its destruction shall not have completed, otherwise the computation of the pointer value (or accessing the member value) results in undefined behavior. [ *Example*:

```
struct A {};
struct B : virtual A {};
```

```

struct C : B { };
struct D : virtual A { D(A*); };
struct X { X(A*); };

struct E : C, D, X {
    E() : D(this),      // undefined: upcast from E* to A* might use path E* → D* → A*
    // but D is not constructed

    // "D((C*)this)" would be defined: E* → C* is defined because E() has started,
    // and C* → A* is defined because C is fully constructed

    X(this) {}          // defined: upon construction of X, C/B/D/A sublattice is fully constructed
};

— end example]

```

- <sup>3</sup> Member functions, including virtual functions (??), can be called during construction or destruction (??). When a virtual function is called directly or indirectly from a constructor or from a destructor, including during the construction or destruction of the class's non-static data members, and the object to which the call applies is the object (call it *x*) under construction or destruction, the function called is the final overrider in the constructor's or destructor's class and not one overriding it in a more-derived class. If the virtual function call uses an explicit class member access (??) and the object expression refers to the complete object of *x* or one of that object's base class subobjects but not *x* or one of its base class subobjects, the behavior is undefined. [Example:

```

struct V {
    virtual void f();
    virtual void g();
};

struct A : virtual V {
    virtual void f();
};

struct B : virtual V {
    virtual void g();
    B(V*, A*);
};

struct D : A, B {
    virtual void f();
    virtual void g();
    D() : B((A*)this, this) {}
};

B::B(V* v, A* a) {
    f();                  // calls V::f, not A::f
    g();                  // calls B::g, not D::g
    v->g();              // v is base of B, the call is well-defined, calls B::g
    a->f();              // undefined behavior, a's type not a base of B
}

```

— end example ]

- <sup>4</sup> The `typeid` operator (??) can be used during construction or destruction (??). When `typeid` is used in a constructor (including the *mem-initializer* or default member initializer (??) for a non-static data member) or in a destructor, or used in a function called (directly or indirectly) from a constructor or destructor, if the operand of `typeid` refers to the object under construction or destruction, `typeid` yields the `std::type_info` object representing the constructor or destructor's class. If the operand of `typeid` refers to the object under construction or destruction and the static type of the operand is neither the constructor or destructor's class nor one of its bases, the behavior is undefined.
- <sup>5</sup> `dynamic_casts` (??) can be used during construction or destruction (??). When a `dynamic_cast` is used in a constructor (including the *mem-initializer* or default member initializer for a non-static data member) or in a destructor, or used in a function called (directly or indirectly) from a constructor or destructor, if the operand of the `dynamic_cast` refers to the object under construction or destruction, this object is considered to be a most derived object that has the type of the constructor or destructor's class. If the operand of the `dynamic_cast` refers to the object under construction or destruction and the static type of the operand is not a pointer to or object of the constructor or destructor's own class or one of its bases, the `dynamic_cast` results in undefined behavior. [ *Example*:

```

struct V {
    virtual void f();
};

struct A : virtual V { };

struct B : virtual V {
    B(V*, A*);
};

struct D : A, B {
    D() : B((A*)this, this) { }
};

B::B(V* v, A* a) {
    typeid(*this);                                // type_info for B
    typeid(*v);                                // well-defined: *v has type V, a base of B yields type_info for B
    typeid(*a);                                // undefined behavior: type A not a base of B
    dynamic_cast<B*>(v);                      // well-defined: v of type V*, V base of B results in B*
    dynamic_cast<B*>(a);                      // undefined behavior, a has type A*, A not a base of B
}

```

— end example ]

## 15.8 Copying and moving class objects

[`class.copy`]

- <sup>1</sup> A class object can be copied or moved in two ways: by initialization (??, ??), including for function argument passing (??) and for function value return (??); and by assignment (??). Conceptually, these two operations are implemented by a copy/move constructor (??) and copy/move assignment operator (??).
- <sup>2</sup> A program is ill-formed if the copy/move constructor or the copy/move assignment operator for an object is implicitly odr-used and the special member function is not accessible (??). [ *Note*: Copying/moving one

object into another using the copy/move constructor or the copy/move assignment operator does not change the layout or size of either object. — *end note*]

### 15.8.1 Copy/move constructors

[**class.copy.ctor**]

- <sup>1</sup> A non-template constructor for class X is a copy constructor if its first parameter is of type `X&`, `const X&`, `volatile X&` or `const volatile X&`, and either there are no other parameters or else all other parameters have default arguments (??). [Example: `X::X(const X&)` and `X::X(X&, int=1)` are copy constructors.

```
struct X {
    X(int);
    X(const X&, int = 1);
};

X a(1);           // calls X(int);
X b(a, 0);       // calls X(const X&, int);
X c = b;          // calls X(const X&, int);
```

— *end example*]

- <sup>2</sup> A non-template constructor for class X is a move constructor if its first parameter is of type `X&&`, `const X&&`, `volatile X&&`, or `const volatile X&&`, and either there are no other parameters or else all other parameters have default arguments (??). [Example: `Y::Y(Y&&)` is a move constructor.

```
struct Y {
    Y(const Y&);
    Y(Y&&);

};

extern Y f(int);
Y d(f(1));        // calls Y(Y&&)
Y e = d;          // calls Y(const Y&)

— end example]
```

- <sup>3</sup> [*Note*: All forms of copy/move constructor may be declared for a class. [Example:

```
struct X {
    X(const X&);
    X(X&);           // OK
    X(X&&);
    X(const X&&);   // OK, but possibly not sensible
};

— end example] — end note]
```

- <sup>4</sup> [*Note*: If a class X only has a copy constructor with a parameter of type `X&`, an initializer of type `const X` or `volatile X` cannot initialize an object of type (possibly cv-qualified) X. [Example:

```
struct X {
    X();                // default constructor
    X(X&);             // copy constructor with a non-const parameter
};

const X cx;
X x = cx;            // error: X::X(X&) cannot copy cx into x

— end example] — end note]
```

- <sup>5</sup> A declaration of a constructor for a class X is ill-formed if its first parameter is of type (optionally cv-qualified) X and either there are no other parameters or else all other parameters have default arguments. A member function template is never instantiated to produce such a constructor signature. [ *Example*:

```
struct S {
    template<typename T> S(T);
    S();
};

S g;

void h() {
    S a(g);           // does not instantiate the member template to produce S::S<S>(S);
                      // uses the implicitly declared copy constructor
}
```

— *end example*]

- <sup>6</sup> If the class definition does not explicitly declare a copy constructor, a non-explicit one is declared *implicitly*. If the class definition declares a move constructor or move assignment operator, the implicitly declared copy constructor is defined as deleted; otherwise, it is defined as defaulted (??). The latter case is deprecated if the class has a user-declared copy assignment operator or a user-declared destructor.

- <sup>7</sup> The implicitly-declared copy constructor for a class X will have the form

`X::X(const X&)`

if each potentially constructed subobject of a class type M (or array thereof) has a copy constructor whose first parameter is of type `const M&` or `const volatile M&`.<sup>120</sup> Otherwise, the implicitly-declared copy constructor will have the form

`X::X(X&)`

- <sup>8</sup> If the definition of a class X does not explicitly declare a move constructor, a non-explicit one will be implicitly declared as defaulted if and only if

- (8.1) — X does not have a user-declared copy constructor,
- (8.2) — X does not have a user-declared copy assignment operator,
- (8.3) — X does not have a user-declared move assignment operator, and
- (8.4) — X does not have a user-declared destructor.

[ *Note*: When the move constructor is not implicitly declared or explicitly supplied, expressions that otherwise would have invoked the move constructor may instead invoke a copy constructor. — *end note* ]

- <sup>9</sup> The implicitly-declared move constructor for class X will have the form

`X::X(X&&)`

- <sup>10</sup> An implicitly-declared copy/move constructor is an inline public member of its class. A defaulted copy/move constructor for a class X is defined as deleted (??) if X has:

- (10.1) — a potentially constructed subobject type M (or array thereof) that cannot be copied/moved because overload resolution (??), as applied to find M's corresponding constructor, results in an ambiguity or a function that is deleted or inaccessible from the defaulted constructor,

---

<sup>120</sup>) This implies that the reference parameter of the implicitly-declared copy constructor cannot bind to a `volatile` lvalue; see ??.

- (10.2) — a variant member whose corresponding constructor as selected by overload resolution is non-trivial,
- (10.3) — any potentially constructed subobject of a type with a destructor that is deleted or inaccessible from the defaulted constructor, or,
- (10.4) — for the copy constructor, a non-static data member of rvalue reference type.

A defaulted move constructor that is defined as deleted is ignored by overload resolution (??, ??). [Note: A deleted move constructor would otherwise interfere with initialization from an rvalue which can use the copy constructor instead. —end note]

- <sup>11</sup> A copy/move constructor for class X is trivial if it is not user-provided and if:
  - (11.1) — class X has no virtual functions (??) and no virtual base classes (??), and
  - (11.2) — the constructor selected to copy/move each direct base class subobject is trivial, and
  - (11.3) — for each non-static data member of X that is of class type (or array thereof), the constructor selected to copy/move that member is trivial;
 otherwise the copy/move constructor is *non-trivial*.
- <sup>12</sup> A copy/move constructor that is defaulted and not defined as deleted is *implicitly defined* when it is odr-used (??), when it is needed for constant evaluation (??), or when it is explicitly defaulted after its first declaration. [Note: The copy/move constructor is implicitly defined even if the implementation elided its odr-use (??, ??). —end note] If the implicitly-defined constructor would satisfy the requirements of a constexpr constructor (??), the implicitly-defined constructor is **constexpr**.
- <sup>13</sup> Before the defaulted copy/move constructor for a class is implicitly defined, all non-user-provided copy/move constructors for its potentially constructed subobjects shall have been implicitly defined. [Note: An implicitly-declared copy/move constructor has an implied exception specification (??). —end note]
- <sup>14</sup> The implicitly-defined copy/move constructor for a non-union class X performs a memberwise copy/move of its bases and members. [Note: Default member initializers of non-static data members are ignored. See also the example in ??, —end note] The order of initialization is the same as the order of initialization of bases and members in a user-defined constructor (see ??). Let x be either the parameter of the constructor or, for the move constructor, an xvalue referring to the parameter. Each base or non-static data member is copied/moved in the manner appropriate to its type:
  - (14.1) — if the member is an array, each element is direct-initialized with the corresponding subobject of x;
  - (14.2) — if a member m has rvalue reference type T&&, it is direct-initialized with `static_cast<T&&>(x.m);`
  - (14.3) — otherwise, the base or member is direct-initialized with the corresponding base or member of x.
 Virtual base class subobjects shall be initialized only once by the implicitly-defined copy/move constructor (see ??).
- <sup>15</sup> The implicitly-defined copy/move constructor for a union X copies the object representation (??) of X.

### 15.8.2 Copy/move assignment operator

[**class.copy.assign**]

- <sup>1</sup> A user-declared copy assignment operator X::operator= is a non-static non-template member function of class X with exactly one parameter of type X, X&, const X&, volatile X& or const volatile X&. <sup>121</sup> [Note: An overloaded assignment operator must be declared to have only one parameter; see ??, —end note]

<sup>121</sup>) Because a template assignment operator or an assignment operator taking an rvalue reference parameter is never a copy assignment operator, the presence of such an assignment operator does not suppress the implicit declaration of a copy assignment operator. Such assignment operators participate in overload resolution with other assignment operators, including copy assignment operators, and, if selected, will be used to assign an object.

[*Note*: More than one form of copy assignment operator may be declared for a class. — *end note*] [*Note*: If a class X only has a copy assignment operator with a parameter of type X&, an expression of type const X cannot be assigned to an object of type X. [*Example*:

```
struct X {
    X();
    X& operator=(X&);
};

const X cx;
X x;
void f() {
    x = cx;           // error: X::operator=(X&) cannot assign cx into x
}
```

— *end example*] — *end note*]

- 2 If the class definition does not explicitly declare a copy assignment operator, one is declared *implicitly*. If the class definition declares a move constructor or move assignment operator, the implicitly declared copy assignment operator is defined as deleted; otherwise, it is defined as defaulted (??). The latter case is deprecated if the class has a user-declared copy constructor or a user-declared destructor. The implicitly-declared copy assignment operator for a class X will have the form

`X& X::operator=(const X&)`

if

- (2.1) — each direct base class B of X has a copy assignment operator whose parameter is of type `const B&`, `const volatile B&` or `B`, and
- (2.2) — for all the non-static data members of X that are of a class type M (or array thereof), each such class type has a copy assignment operator whose parameter is of type `const M&`, `const volatile M&` or `M`.<sup>122</sup>

Otherwise, the implicitly-declared copy assignment operator will have the form

`X& X::operator=(X&)`

- 3 A user-declared move assignment operator `X::operator=` is a non-static non-template member function of class X with exactly one parameter of type `X&&`, `const X&&`, `volatile X&&`, or `const volatile X&&`. [*Note*: An overloaded assignment operator must be declared to have only one parameter; see ??.. — *end note*] [*Note*: More than one form of move assignment operator may be declared for a class. — *end note*]

- 4 If the definition of a class X does not explicitly declare a move assignment operator, one will be implicitly declared as defaulted if and only if

- (4.1) — X does not have a user-declared copy constructor,
- (4.2) — X does not have a user-declared move constructor,
- (4.3) — X does not have a user-declared copy assignment operator, and
- (4.4) — X does not have a user-declared destructor.

[*Example*: The class definition

```
struct S {
    int a;
```

---

<sup>122</sup>) This implies that the reference parameter of the implicitly-declared copy assignment operator cannot bind to a `volatile` value; see ??.

```
S& operator=(const S&) = default;
};
```

will not have a default move assignment operator implicitly declared because the copy assignment operator has been user-declared. The move assignment operator may be explicitly defaulted.

```
struct S {
    int a;
    S& operator=(const S&) = default;
    S& operator=(S&&) = default;
};

— end example ]
```

- <sup>5</sup> The implicitly-declared move assignment operator for a class X will have the form

```
X& X::operator=(X&&);
```

- <sup>6</sup> The implicitly-declared copy/move assignment operator for class X has the return type X&; it returns the object for which the assignment operator is invoked, that is, the object assigned to. An implicitly-declared copy/move assignment operator is an inline public member of its class.

- <sup>7</sup> A defaulted copy/move assignment operator for class X is defined as deleted if X has:

- (7.1) — a variant member with a non-trivial corresponding assignment operator and X is a union-like class, or
- (7.2) — a non-static data member of const non-class type (or array thereof), or
- (7.3) — a non-static data member of reference type, or
- (7.4) — a direct non-static data member of class type M (or array thereof) or a direct base class M that cannot be copied/moved because overload resolution (??), as applied to find M's corresponding assignment operator, results in an ambiguity or a function that is deleted or inaccessible from the defaulted assignment operator.

A defaulted move assignment operator that is defined as deleted is ignored by overload resolution (??, ??).

- <sup>8</sup> Because a copy/move assignment operator is implicitly declared for a class if not declared by the user, a base class copy/move assignment operator is always hidden by the corresponding assignment operator of a derived class (??). A *using-declaration* (??) that brings in from a base class an assignment operator with a parameter type that could be that of a copy/move assignment operator for the derived class is not considered an explicit declaration of such an operator and does not suppress the implicit declaration of the derived class operator; the operator introduced by the *using-declaration* is hidden by the implicitly-declared operator in the derived class.

- <sup>9</sup> A copy/move assignment operator for class X is trivial if it is not user-provided and if:

- (9.1) — class X has no virtual functions (??) and no virtual base classes (??), and
- (9.2) — the assignment operator selected to copy/move each direct base class subobject is trivial, and
- (9.3) — for each non-static data member of X that is of class type (or array thereof), the assignment operator selected to copy/move that member is trivial;

otherwise the copy/move assignment operator is *non-trivial*.

- <sup>10</sup> A copy/move assignment operator for a class X that is defaulted and not defined as deleted is *implicitly defined* when it is odr-used (??) (e.g., when it is selected by overload resolution to assign to an object of its class type), when it is needed for constant evaluation (??), or when it is explicitly defaulted after its first declaration. The implicitly-defined copy/move assignment operator is constexpr if

- (10.1) —  $X$  is a literal type, and
- (10.2) — the assignment operator selected to copy/move each direct base class subobject is a `constexpr` function, and
- (10.3) — for each non-static data member of  $X$  that is of class type (or array thereof), the assignment operator selected to copy/move that member is a `constexpr` function.

- <sup>11</sup> Before the defaulted copy/move assignment operator for a class is implicitly defined, all non-user-provided copy/move assignment operators for its direct base classes and its non-static data members shall have been implicitly defined. [Note: An implicitly-declared copy/move assignment operator has an implied exception specification (??). —end note]
- <sup>12</sup> The implicitly-defined copy/move assignment operator for a non-union class  $X$  performs memberwise copy/move assignment of its subobjects. The direct base classes of  $X$  are assigned first, in the order of their declaration in the *base-specifier-list*, and then the immediate non-static data members of  $X$  are assigned, in the order in which they were declared in the class definition. Let  $x$  be either the parameter of the function or, for the move operator, an *xvalue* referring to the parameter. Each subobject is assigned in the manner appropriate to its type:

- (12.1) — if the subobject is of class type, as if by a call to `operator=` with the subobject as the object expression and the corresponding subobject of  $x$  as a single function argument (as if by explicit qualification; that is, ignoring any possible virtual overriding functions in more derived classes);
- (12.2) — if the subobject is an array, each element is assigned, in the manner appropriate to the element type;
- (12.3) — if the subobject is of scalar type, the built-in assignment operator is used.

It is unspecified whether subobjects representing virtual base classes are assigned more than once by the implicitly-defined copy/move assignment operator. [Example:

```
struct V { };
struct A : virtual V { };
struct B : virtual V { };
struct C : B, A { };
```

It is unspecified whether the virtual base class subobject  $V$  is assigned twice by the implicitly-defined copy/move assignment operator for  $C$ . —end example]

- <sup>13</sup> The implicitly-defined copy assignment operator for a union  $X$  copies the object representation (??) of  $X$ .

### 15.8.3 Copy/move elision

[`class.copy.elision`]

- <sup>1</sup> When certain criteria are met, an implementation is allowed to omit the copy/move construction of a class object, even if the constructor selected for the copy/move operation and/or the destructor for the object have side effects. In such cases, the implementation treats the source and target of the omitted copy/move operation as simply two different ways of referring to the same object. If the first parameter of the selected constructor is an *rvalue* reference to the object's type, the destruction of that object occurs when the target would have been destroyed; otherwise, the destruction occurs at the later of the times when the two objects would have been destroyed without the optimization.<sup>123</sup> This elision of copy/move operations, called *copy elision*, is permitted in the following circumstances (which may be combined to eliminate multiple copies):

- (1.1) — in a `return` statement in a function with a class return type, when the *expression* is the name of a non-volatile automatic object (other than a function parameter or a variable introduced by the

---

<sup>123</sup> Because only one object is destroyed instead of two, and one copy/move constructor is not executed, there is still one object destroyed for each one constructed.

*exception-declaration* of a *handler* (??) with the same type (ignoring cv-qualification) as the function return type, the copy/move operation can be omitted by constructing the automatic object directly into the function call's return object

- (1.2) — in a *throw-expression* (??), when the operand is the name of a non-volatile automatic object (other than a function or catch-clause parameter) whose scope does not extend beyond the end of the innermost enclosing *try-block* (if there is one), the copy/move operation from the operand to the exception object (??) can be omitted by constructing the automatic object directly into the exception object
- (1.3) — when the *exception-declaration* of an exception handler (??) declares an object of the same type (except for cv-qualification) as the exception object (??), the copy operation can be omitted by treating the *exception-declaration* as an alias for the exception object if the meaning of the program will be unchanged except for the execution of constructors and destructors for the object declared by the *exception-declaration*. [Note: There cannot be a move from the exception object because it is always an lvalue. —end note]

Copy elision is required where an expression is evaluated in a context requiring a constant expression (??) and in constant initialization (??). [Note: Copy elision might not be performed if the same expression is evaluated in another context. —end note]

<sup>2</sup> [Example:

```
class Thing {
public:
    Thing();
    ~Thing();
    Thing(const Thing&);
};

Thing f() {
    Thing t;
    return t;
}

Thing t2 = f();

struct A {
    void *p;
    constexpr A(): p(this) {}
};

constexpr A g() {
    A a;
    return a;
}

constexpr A a;           // well-formed, a.p points to a
constexpr A b = g();    // well-formed, b.p points to b

void g() {
    A c = g();          // well-formed, c.p may point to c or to an ephemeral temporary
}
```

Here the criteria for elision can eliminate the copying of the local automatic object `t` into the result object for the function call `f()`, which is the global object `t2`. Effectively, the construction of the local object `t` can be viewed as directly initializing the global object `t2`, and that object's destruction will occur at program exit. Adding a move constructor to `Thing` has the same effect, but it is the move construction from the local automatic object to `t2` that is elided. — *end example*]

- 3 In the following copy-initialization contexts, a move operation might be used instead of a copy operation:
  - (3.1) — If the *expression* in a `return` statement (??) is a (possibly parenthesized) *id-expression* that names an object with automatic storage duration declared in the body or *parameter-declaration-clause* of the innermost enclosing function or *lambda-expression*, or
  - (3.2) — if the operand of a *throw-expression* (??) is the name of a non-volatile automatic object (other than a function or catch-clause parameter) whose scope does not extend beyond the end of the innermost enclosing *try-block* (if there is one),

overload resolution to select the constructor for the copy is first performed as if the object were designated by an rvalue. If the first overload resolution fails or was not performed, or if the type of the first parameter of the selected constructor is not an rvalue reference to the object's type (possibly cv-qualified), overload resolution is performed again, considering the object as an lvalue. [ *Note:* This two-stage overload resolution must be performed regardless of whether copy elision will occur. It determines the constructor to be called if elision is not performed, and the selected constructor must be accessible even if the call is elided. — *end note* ]

- 4 [ *Example:*

```
class Thing {
public:
    Thing();
    ~Thing();
    Thing(Thing&&);

private:
    Thing(const Thing&);

};

Thing f(bool b) {
    Thing t;
    if (b)
        throw t;           // OK: Thing(Thing&&) used (or elided) to throw t
    return t;               // OK: Thing(Thing&&) used (or elided) to return t
}

Thing t2 = f(false);    // OK: no extra copy/move performed, t2 constructed by call to f

struct Weird {
    Weird();
    Weird(Weird&);

};

Weird g() {
    Weird w;
```

```

    return w;           // OK: first overload resolution fails, second overload resolution selects Weird(Weird&)
}
— end example]

```

## 15.9 Comparisons

[class.compare]

### 15.9.1 Defaulted comparison operator functions

[class.compare.default]

- <sup>1</sup> A defaulted comparison operator function (??, ??, ??) for some class C shall be a non-template function declared in the *member-specification* of C that is

- (1.1) — a non-static member of C having one parameter of type const C&, or
- (1.2) — a friend of C having two parameters of type const C&.

### 15.9.2 Three-way comparison

[class.spaceship]

- <sup>1</sup> The direct base class subobjects of C, in the order of their declaration in the *base-specifier-list* of C, followed by the non-static data members of C, in the order of their declaration in the *member-specification* of C, form a list of subobjects. In that list, any subobject of array type is recursively expanded to the sequence of its elements, in the order of increasing subscript. Let  $x_i$  be an lvalue denoting the  $i^{\text{th}}$  element in the expanded list of subobjects for an object x (of length n), where  $x_i$  is formed by a sequence of derived-to-base conversions (??), class member access expressions (??), and array subscript expressions (??) applied to x. The type of the expression  $x_i \leqslant x_i$  is denoted by  $R_i$ . It is unspecified whether virtual base class subobjects are compared more than once.
- <sup>2</sup> If the declared return type of a defaulted three-way comparison operator function is auto, then the return type is deduced as the common comparison type (see below) of  $R_0, R_1, \dots, R_{n-1}$ . [Note: Otherwise, the program will be ill-formed if the expression  $x_i \leqslant x_i$  is not implicitly convertible to the declared return type for any i. — end note] If the return type is deduced as void, the operator function is defined as deleted.
- <sup>3</sup> The return value V of type R of the defaulted three-way comparison operator function with parameters x and y of the same type is determined by comparing corresponding elements  $x_i$  and  $y_i$  in the expanded lists of subobjects for x and y until the first index i where  $x_i \leqslant y_i$  yields a result value  $v_i$  where  $v_i \neq 0$ , contextually converted to bool, yields true; V is  $v_i$  converted to R. If no such index exists, V is std::strong\_ordering::equal converted to R.
- <sup>4</sup> The common comparison type U of a possibly-empty list of n types  $T_0, T_1, \dots, T_{n-1}$  is defined as follows:
- (4.1) — If any  $T_i$  is not a comparison category type (??), U is void.
  - (4.2) — Otherwise, if at least one  $T_i$  is std::weak\_equality, or at least one  $T_i$  is std::strong\_equality and at least one  $T_j$  is std::partial\_ordering or std::weak\_ordering, U is std::weak\_equality (??).
  - (4.3) — Otherwise, if at least one  $T_i$  is std::strong\_equality, U is std::strong\_equality (??).
  - (4.4) — Otherwise, if at least one  $T_i$  is std::partial\_ordering, U is std::partial\_ordering (??).
  - (4.5) — Otherwise, if at least one  $T_i$  is std::weak\_ordering, U is std::weak\_ordering (??).
  - (4.6) — Otherwise, U is std::strong\_ordering (??). [Note: In particular, this is the result when n is 0. — end note]

### 15.9.3 Other comparison operators

[class.rel.eq]

- <sup>1</sup> A defaulted relational (??) or equality (??) operator function for some operator @ shall have a declared return type bool.

<sup>2</sup> The operator function with parameters  $x$  and  $y$  is defined as deleted if

- (2.1) — overload resolution (??), as applied to  $x \leqslant y$  (also considering synthesized candidates with reversed order of parameters (??)), results in an ambiguity or a function that is deleted or inaccessible from the operator function, or
- (2.2) — the operator @ cannot be applied to the return type of  $x \leqslant y$  or  $y \leqslant x$ .

Otherwise, the operator function yields  $x \leqslant y @ 0$  if an `operator<=` with the original order of parameters was selected, or  $0 @ y \leqslant x$  otherwise.

<sup>3</sup> [*Example:*

```
struct C {
    friend std::strong_equality operator<=(const C&, const C&);
    friend bool operator==(const C& x, const C& y) = default; // OK, returns x <= y == 0
    bool operator<(const C&) = default;                      // OK, function is deleted
};
```

— end example]

# 16 Overloading [over]

- <sup>1</sup> When two or more different declarations are specified for a single name in the same scope, that name is said to be *overloaded*, and the declarations are called *overloaded declarations*. Only function and function template declarations can be overloaded; variable and type declarations cannot be overloaded.
- <sup>2</sup> When an overloaded function name is used in a call, which overloaded function declaration is being referenced is determined by comparing the types of the arguments at the point of use with the types of the parameters in the overloaded declarations that are visible at the point of use. This function selection process is called *overload resolution* and is defined in ???. [Example:

```
double abs(double);
int abs(int);

abs(1);           // calls abs(int);
abs(1.0);        // calls abs(double);

— end example]
```

## 16.1 Overloadable declarations

[over.load]

- 1 Not all function declarations can be overloaded. Those that cannot be overloaded are specified here. A program is ill-formed if it contains two such non-overloadable declarations in the same scope. [Note: This restriction applies to explicit declarations in a scope, and between such declarations and declarations made through a *using-declaration* (??). It does not apply to sets of functions fabricated as a result of name lookup (e.g., because of *using-directives*) or overload resolution (e.g., for operator functions). — end note]

- 2 Certain function declarations cannot be overloaded:

- (2.1) — Function declarations that differ only in the return type, the exception specification (??), or both cannot be overloaded.
- (2.2) — Member function declarations with the same name and the same parameter-type-list (??) cannot be overloaded if any of them is a **static** member function declaration (??). Likewise, member function template declarations with the same name, the same parameter-type-list, and the same template parameter lists cannot be overloaded if any of them is a **static** member function template declaration. The types of the implicit object parameters constructed for the member functions for the purpose of overload resolution (??) are not considered when comparing parameter-type-lists for enforcement of this rule. In contrast, if there is no **static** member function declaration among a set of member function declarations with the same name and the same parameter-type-list, then these member function declarations can be overloaded if they differ in the type of their implicit object parameter. [Example: The following illustrates this distinction:

```
class X {
    static void f();
    void f();           // ill-formed
    void f() const;    // ill-formed
    void f() const volatile; // ill-formed
    void g();
    void g() const;   // OK: no static g
```

```

    void g() const volatile;      // OK: no static g
};

— end example]
```

- (2.3) — Member function declarations with the same name and the same parameter-type-list (??) as well as member function template declarations with the same name, the same parameter-type-list, and the same template parameter lists cannot be overloaded if any of them, but not all, have a *ref-qualifier* (??). [Example:

```

class Y {
    void h() &;                      // OK
    void h() const &;                // OK, all declarations have a ref-qualifier
    void h() &&;                   // ill-formed, prior declaration of h
    void i() &;                     // ill-formed, prior declaration of i
    void i() const;                 // has a ref-qualifier
};
```

— end example]

- 3 [Note: As specified in ??, function declarations that have equivalent parameter declarations and *requires-clauses*, if any (??), declare the same function and therefore cannot be overloaded:

- (3.1) — Parameter declarations that differ only in the use of equivalent *typedef “types”* are equivalent. A *typedef* is not a separate type, but only a synonym for another type (??). [Example:

```

typedef int Int;

void f(int i);
void f(Int i);                  // OK: redeclaration of f(int)
void f(int i) { /* ... */ }
void f(Int i) { /* ... */ }     // error: redefinition of f(int)
```

— end example]

Enumerations, on the other hand, are distinct types and can be used to distinguish overloaded function declarations. [Example:

```

enum E { a };

void f(int i) { /* ... */ }
void f(E i) { /* ... */ }

— end example]
```

- (3.2) — Parameter declarations that differ only in a pointer \* versus an array [] are equivalent. That is, the array declaration is adjusted to become a pointer declaration (??). Only the second and subsequent array dimensions are significant in parameter types (??). [Example:

```

int f(char*);
int f(char[]);
int f(char[7]);
int f(char[9]);                 // same as f(char*);

int g(char(*)[10]);
int g(char[5][10]);             // same as g(char(*)[10]);
```

```

int g(char[7][10]);           // same as g(char(*)[10]);
int g(char(*)[20]);           // different from g(char(*)[10]);
— end example]

```

- (3.3) — Parameter declarations that differ only in that one is a function type and the other is a pointer to the same function type are equivalent. That is, the function type is adjusted to become a pointer to function type (??). [Example:

```

void h(int());
void h(int (*)());           // redeclaration of h(int())
void h(int x()) { }          // definition of h(int())
void h(int (*x)()) { }        // ill-formed: redefinition of h(int())

```

— end example]

- (3.4) — Parameter declarations that differ only in the presence or absence of `const` and/or `volatile` are equivalent. That is, the `const` and `volatile` type-specifiers for each parameter type are ignored when determining which function is being declared, defined, or called. [Example:

```

typedef const int cInt;

int f (int);
int f (const int);           // redeclaration of f(int)
int f (int) { /* ... */ }     // definition of f(int)
int f (cInt) { /* ... */ }    // error: redefinition of f(int)

```

— end example]

Only the `const` and `volatile` type-specifiers at the outermost level of the parameter type specification are ignored in this fashion; `const` and `volatile` type-specifiers buried within a parameter type specification are significant and can be used to distinguish overloaded function declarations.<sup>124</sup> In particular, for any type `T`, “pointer to `T`”, “pointer to `const T`”, and “pointer to `volatile T`” are considered distinct parameter types, as are “reference to `T`”, “reference to `const T`”, and “reference to `volatile T`”.

- (3.5) — Two parameter declarations that differ only in their default arguments are equivalent. [Example:  
Consider the following:

```

void f (int i, int j);
void f (int i, int j = 99);    // OK: redeclaration of f(int, int)
void f (int i = 88, int j);    // OK: redeclaration of f(int, int)
void f ();                     // OK: overloaded declaration of f

void prog () {
    f (1, 2);                 // OK: call f(int, int)
    f (1);                    // OK: call f(int, int)
    f ();                      // error: f(int, int) or f()?
}

— end example]

```

— end note]

---

<sup>124)</sup> When a parameter type includes a function type, such as in the case of a parameter type that is a pointer to function, the `const` and `volatile` type-specifiers at the outermost level of the parameter type specifications for the inner function type are also ignored.

## 16.2 Declaration matching

[over.dcl]

- <sup>1</sup> Two function declarations of the same name refer to the same function if they are in the same scope and have equivalent parameter declarations (??) and equivalent trailing *requires-clauses*, if any (??). A function member of a derived class is *not* in the same scope as a function member of the same name in a base class. [Example:

```
struct B {
    int f(int);
};

struct D : B {
    int f(const char*);
};
```

Here D::f(const char\*) hides B::f(int) rather than overloading it.

```
void h(D* pd) {
    pd->f(1);           // error:
                        // D::f(const char*) hides B::f(int)
    pd->B::f(1);       // OK
    pd->f("Ben");     // OK, calls D::f
}
```

— end example]

- <sup>2</sup> A locally declared function is not in the same scope as a function in a containing scope. [Example:

```
void f(const char*);
void g() {
    extern void f(int);
    f("asdf");          // error: f(int) hides f(const char*)
                        // so there is no f(const char*) in this scope
}
```

```
void caller () {
    extern void callee(int, int);
    {
        extern void callee(int);   // hides callee(int, int)
        callee(88, 99);          // error: only callee(int) in scope
    }
}
```

— end example]

- <sup>3</sup> Different versions of an overloaded member function can be given different access rules. [Example:

```
class buffer {
private:
    char* p;
    int size;
protected:
    buffer(int s, char* store) { size = s; p = store; }
public:
    buffer(int s) { p = new char[size = s]; }
};
```

— end example]

## 16.3 Overload resolution

[**over.match**]

- <sup>1</sup> Overload resolution is a mechanism for selecting the best function to call given a list of expressions that are to be the arguments of the call and a set of *candidate functions* that can be called based on the context of the call. The selection criteria for the best function are the number of arguments, how well the arguments match the parameter-type-list of the candidate function, how well (for non-static member functions) the object matches the implicit object parameter, and certain other properties of the candidate function. [ *Note:* The function selected by overload resolution is not guaranteed to be appropriate for the context. Other restrictions, such as the accessibility of the function, can make its use in the calling context ill-formed. — *end note* ]

- <sup>2</sup> Overload resolution selects the function to call in seven distinct contexts within the language:

- (2.1) — invocation of a function named in the function call syntax (??);
- (2.2) — invocation of a function call operator, a pointer-to-function conversion function, a reference-to-pointer-to-function conversion function, or a reference-to-function conversion function on a class object named in the function call syntax (??);
- (2.3) — invocation of the operator referenced in an expression (??);
- (2.4) — invocation of a constructor for default- or direct-initialization (??) of a class object (??);
- (2.5) — invocation of a user-defined conversion for copy-initialization (??) of a class object (??);
- (2.6) — invocation of a conversion function for initialization of an object of a non-class type from an expression of class type (??); and
- (2.7) — invocation of a conversion function for conversion to a glvalue or class prvalue to which a reference (??) will be directly bound (??).

Each of these contexts defines the set of candidate functions and the list of arguments in its own unique way. But, once the candidate functions and argument lists have been identified, the selection of the best function is the same in all cases:

- (2.8) — First, a subset of the candidate functions (those that have the proper number of arguments and meet certain other conditions) is selected to form a set of viable functions (??).
  - (2.9) — Then the best viable function is selected based on the implicit conversion sequences (??) needed to match each argument to the corresponding parameter of each viable function.
- <sup>3</sup> If a best viable function exists and is unique, overload resolution succeeds and produces it as the result. Otherwise overload resolution fails and the invocation is ill-formed. When overload resolution succeeds, and the best viable function is not accessible (??) in the context in which it is used, the program is ill-formed.

### 16.3.1 Candidate functions and argument lists

[**over.match.funcs**]

- <sup>1</sup> The subclauses of ?? describe the set of candidate functions and the argument list submitted to overload resolution in each context in which overload resolution is used. The source transformations and constructions defined in these subclauses are only for the purpose of describing the overload resolution process. An implementation is not required to use such transformations and constructions.
- <sup>2</sup> The set of candidate functions can contain both member and non-member functions to be resolved against the same argument list. So that argument and parameter lists are comparable within this heterogeneous set, a member function is considered to have an extra parameter, called the *implicit object parameter*, which

represents the object for which the member function has been called. For the purposes of overload resolution, both static and non-static member functions have an implicit object parameter, but constructors do not.

- <sup>3</sup> Similarly, when appropriate, the context can construct an argument list that contains an *implied object argument* to denote the object to be operated on. Since arguments and parameters are associated by position within their respective lists, the convention is that the implicit object parameter, if present, is always the first parameter and the implied object argument, if present, is always the first argument.

- <sup>4</sup> For non-static member functions, the type of the implicit object parameter is

- (4.1) — “lvalue reference to *cv X*” for functions declared without a *ref-qualifier* or with the `&` *ref-qualifier*
- (4.2) — “rvalue reference to *cv X*” for functions declared with the `&&` *ref-qualifier*

where *X* is the class of which the function is a member and *cv* is the *cv-qualification* on the member function declaration. [ *Example*: For a `const` member function of class *X*, the extra parameter is assumed to have type “reference to `const X`”. — *end example* ] For conversion functions, the function is considered to be a member of the class of the implied object argument for the purpose of defining the type of the implicit object parameter. For non-conversion functions introduced by a *using-declaration* into a derived class, the function is considered to be a member of the derived class for the purpose of defining the type of the implicit object parameter. For static member functions, the implicit object parameter is considered to match any object (since if the function is selected, the object is discarded). [ *Note*: No actual type is established for the implicit object parameter of a static member function, and no attempt will be made to determine a conversion sequence for that parameter (??). — *end note* ]

- <sup>5</sup> During overload resolution, the implied object argument is indistinguishable from other arguments. The implicit object parameter, however, retains its identity since no user-defined conversions can be applied to achieve a type match with it. For non-static member functions declared without a *ref-qualifier*, an additional rule applies:

- (5.1) — even if the implicit object parameter is not `const`-qualified, an rvalue can be bound to the parameter as long as in all other respects the argument can be converted to the type of the implicit object parameter. [ *Note*: The fact that such an argument is an rvalue does not affect the ranking of implicit conversion sequences (??). — *end note* ]

- <sup>6</sup> Because other than in list-initialization only one user-defined conversion is allowed in an implicit conversion sequence, special rules apply when selecting the best user-defined conversion (??, ??). [ *Example*:

```
class T {
public:
    T();
};

class C : T {
public:
    C(int);
};
T a = 1;           // ill-formed: T(C(1)) not tried
— end example ]
```

- <sup>7</sup> In each case where a candidate is a function template, candidate function template specializations are generated using template argument deduction (??, ??). Those candidates are then handled as candidate

functions in the usual way.<sup>125</sup> A given name can refer to one or more function templates and also to a set of overloaded non-template functions. In such a case, the candidate functions generated from each function template are combined with the set of non-template candidate functions.

- 8 A defaulted move special function (??) that is defined as deleted is excluded from the set of candidate functions in all contexts.

### 16.3.1.1 Function call syntax

[over.match.call]

- <sup>1</sup> In a function call (??)

*postfix-expression* ( *expression-list<sub>opt</sub>* )

if the *postfix-expression* denotes a set of overloaded functions and/or function templates, overload resolution is applied as specified in ???. If the *postfix-expression* denotes an object of class type, overload resolution is applied as specified in ???.

- 2 If the *postfix-expression* denotes the address of a set of overloaded functions and/or function templates, overload resolution is applied using that set as described above. If the function selected by overload resolution is a non-static member function, the program is ill-formed. [ *Note:* The resolution of the address of an overload set in other contexts is described in ???. — *end note* ]

#### 16.3.1.1.1 Call to named function

[over.call.func]

- <sup>1</sup> Of interest in ?? are only those function calls in which the *postfix-expression* ultimately contains a name that denotes one or more functions that might be called. Such a *postfix-expression*, perhaps nested arbitrarily deep in parentheses, has one of the following forms:

*postfix-expression*:

*postfix-expression* . *id-expression*  
*postfix-expression* -> *id-expression*  
*primary-expression*

These represent two syntactic subcategories of function calls: qualified function calls and unqualified function calls.

- 2 In qualified function calls, the name to be resolved is an *id-expression* and is preceded by an -> or . operator. Since the construct A->B is generally equivalent to (\*A).B, the rest of ?? assumes, without loss of generality, that all member function calls have been normalized to the form that uses an object and the . operator. Furthermore, ?? assumes that the *postfix-expression* that is the left operand of the . operator has type “cv T” where T denotes a class.<sup>126</sup> Under this assumption, the *id-expression* in the call is looked up as a member function of T following the rules for looking up names in classes (??). The function declarations found by that lookup constitute the set of candidate functions. The argument list is the *expression-list* in the call augmented by the addition of the left operand of the . operator in the normalized member function call as the implied object argument (??).
- 3 In unqualified function calls, the name is not qualified by an -> or . operator and has the more general form of a *primary-expression*. The name is looked up in the context of the function call following the normal rules for name lookup in function calls (??). The function declarations found by that lookup constitute the set of candidate functions. Because of the rules for name lookup, the set of candidate functions consists

<sup>125</sup>) The process of argument deduction fully determines the parameter types of the function template specializations, i.e., the parameters of function template specializations contain no template parameter types. Therefore, except where specified otherwise, function template specializations and non-template functions (??) are treated equivalently for the remainder of overload resolution.

<sup>126</sup>) Note that cv-qualifiers on the type of objects are significant in overload resolution for both glvalue and class prvalue objects.

(1) entirely of non-member functions or (2) entirely of member functions of some class T. In case (1), the argument list is the same as the *expression-list* in the call. In case (2), the argument list is the *expression-list* in the call augmented by the addition of an implied object argument as in a qualified function call. If the keyword `this` (??) is in scope and refers to class T, or a derived class of T, then the implied object argument is (`*this`). If the keyword `this` is not in scope or refers to another class, then a contrived object of type T becomes the implied object argument.<sup>127</sup> If the argument list is augmented by a contrived object and overload resolution selects one of the non-static member functions of T, the call is ill-formed.

### 16.3.1.1.2 Call to object of class type

[`over.call.object`]

- <sup>1</sup> If the *postfix-expression* E in the function call syntax evaluates to a class object of type “cv T”, then the set of candidate functions includes at least the function call operators of T. The function call operators of T are obtained by ordinary lookup of the name `operator()` in the context of (E).`operator()`.
- <sup>2</sup> In addition, for each non-explicit conversion function declared in T of the form

```
operator conversion-type-id () cv-qualifier ref-qualifieropt noexcept-specifieropt attribute-specifier-seqopt ;
```

where *cv-qualifier* is the same cv-qualification as, or a greater cv-qualification than, *cv*, and where *conversion-type-id* denotes the type “pointer to function of (P<sub>1</sub>, …, P<sub>n</sub>) returning R”, or the type “reference to pointer to function of (P<sub>1</sub>, …, P<sub>n</sub>) returning R”, or the type “reference to function of (P<sub>1</sub>, …, P<sub>n</sub>) returning R”, a *surrogate call function* with the unique name *call-function* and having the form

```
R call-function ( conversion-type-id F, P1 a1, …, Pn an) { return F (a1, …, an); }
```

is also considered as a candidate function. Similarly, surrogate call functions are added to the set of candidate functions for each non-explicit conversion function declared in a base class of T provided the function is not hidden within T by another intervening declaration.<sup>128</sup>

- <sup>3</sup> If such a surrogate call function is selected by overload resolution, the corresponding conversion function will be called to convert E to the appropriate function pointer or reference, and the function will then be invoked with the arguments of the call. If the conversion function cannot be called (e.g., because of an ambiguity), the program is ill-formed.
- <sup>4</sup> The argument list submitted to overload resolution consists of the argument expressions present in the function call syntax preceded by the implied object argument (E). [Note: When comparing the call against the function call operators, the implied object argument is compared against the implicit object parameter of the function call operator. When comparing the call against a surrogate call function, the implied object argument is compared against the first parameter of the surrogate call function. The conversion function from which the surrogate call function was derived will be used in the conversion sequence for that parameter since it converts the implied object argument to the appropriate function pointer or reference required by that first parameter. — end note] [Example:

```
int f1(int);
int f2(float);
typedef int (*fp1)(int);
typedef int (*fp2)(float);
struct A {
    operator fp1() { return f1; }
```

<sup>127</sup>) An implied object argument must be contrived to correspond to the implicit object parameter attributed to member functions during overload resolution. It is not used in the call to the selected function. Since the member functions all have the same implicit object parameter, the contrived object will not be the cause to select or reject a function.

<sup>128</sup>) Note that this construction can yield candidate call functions that cannot be differentiated one from the other by overload resolution because they have identical declarations or differ only in their return type. The call will be ambiguous if overload resolution cannot select a match to the call that is uniquely better than such undifferentiable functions.

```

operator fp2() { return f2; }
} a;
int i = a(1);           // calls f1 via pointer returned from conversion function
— end example]

```

### 16.3.1.2 Operators in expressions

[over.match.oper]

- 1 If no operand of an operator in an expression has a type that is a class or an enumeration, the operator is assumed to be a built-in operator and interpreted according to ?? [Note: Because ., .\*, and :: cannot be overloaded, these operators are always built-in operators interpreted according to ??]. ?: cannot be overloaded, but the rules in this subclause are used to determine the conversions to be applied to the second and third operands when they have class or enumeration type (??). — end note] [Example:

```

struct String {
    String (const String&);
    String (const char*);
    operator const char* () ;
};

String operator + (const String&, const String&);

void f() {
    const char* p= "one" + "two"; // ill-formed because neither operand has class or enumeration type
    int I = 1 + 1;             // always evaluates to 2 even if class or enumeration types exist
                               // that would perform the operation.
}

— end example]

```

- 2 If either operand has a type that is a class or an enumeration, a user-defined operator function might be declared that implements this operator or a user-defined conversion can be necessary to convert the operand to a type that is appropriate for a built-in operator. In this case, overload resolution is used to determine which operator function or built-in operator is to be invoked to implement the operator. Therefore, the operator notation is first transformed to the equivalent function-call notation as summarized in Table ?? (where @ denotes one of the operators covered in the specified subclause). However, the operands are sequenced in the order prescribed for the built-in operator (??).

Table 12 — Relationship between operator and function call notation

Subclause	Expression	As member function	As non-member function
??	@a	(a).operator@ ()	operator@(a)
??	a@b	(a).operator@ (b)	operator@(a, b)
??	a=b	(a).operator= (b)	
??	a[b]	(a).operator[] (b)	
??	a->	(a).operator->()	
??	a@	(a).operator@ (0)	operator@(a, 0)

- 3 For a unary operator @ with an operand of a type whose cv-unqualified version is T1, and for a binary operator @ with a left operand of a type whose cv-unqualified version is T1 and a right operand of a type whose cv-unqualified version is T2, three sets of candidate functions, designated *member candidates*, *non-member candidates* and *built-in candidates*, are constructed as follows:

- (3.1) — If T1 is a complete class type or a class currently being defined, the set of member candidates is the result of the qualified lookup of T1::operator@ (??); otherwise, the set of member candidates is empty.

- (3.2) — The set of non-member candidates is the result of the unqualified lookup of `operator@` in the context of the expression according to the usual rules for name lookup in unqualified function calls (??) except that all member functions are ignored. However, if no operand has a class type, only those non-member functions in the lookup set that have a first parameter of type T1 or “reference to cv T1”, when T1 is an enumeration type, or (if there is a right operand) a second parameter of type T2 or “reference to cv T2”, when T2 is an enumeration type, are candidate functions.
- (3.3) — For the operator `,`, the unary operator `&`, or the operator `->`, the built-in candidates set is empty. For all other operators, the built-in candidates include all of the candidate operator functions defined in ?? that, compared to the given operator,
  - (3.3.1) — have the same operator name, and
  - (3.3.2) — accept the same number of operands, and
  - (3.3.3) — accept operand types to which the given operand or operands can be converted according to ??, and
  - (3.3.4) — do not have the same parameter-type-list as any non-member candidate that is not a function template specialization.

<sup>4</sup> For the built-in assignment operators, conversions of the left operand are restricted as follows:

- (4.1) — no temporaries are introduced to hold the left operand, and
- (4.2) — no user-defined conversions are applied to the left operand to achieve a type match with the left-most parameter of a built-in candidate.

<sup>5</sup> For all other operators, no such restrictions apply.

<sup>6</sup> The set of candidate functions for overload resolution for some operator `@` is the union of the member candidates, the non-member candidates, and the built-in candidates for that operator `@`. If that operator is a relational (??) or equality (??) operator with operands `x` and `y`, then for each member, non-member, or built-in candidate for the operator `<=>`:

- (6.1) — that operator is added to the set of candidate functions for overload resolution if `x <=> y @ 0` is well-formed using that `operator<=>`; and
- (6.2) — a synthesized candidate is added to the candidate set where the order of the two parameters is reversed if `0 @ y <=> x` is well-formed using that `operator<=>`;

where in each case `operator<=>` candidates are not considered for the recursive lookup of operator `@`.

<sup>7</sup> The argument list contains all of the operands of the operator. The best function from the set of candidate functions is selected according to ?? and ??.<sup>129</sup> [Example:

```
struct A {
    operator int();
};

A operator+(const A&, const A&);

void m() {
    A a, b;
    a + b; // operator+(a, b) chosen over int(a) + int(b)
}
```

— end example]

---

<sup>129</sup>) If the set of candidate functions is empty, overload resolution is unsuccessful.

- <sup>8</sup> If an `operator<=>` candidate is selected by overload resolution for an operator `@`, but `@` is not `<=>`, `x @ y` is interpreted as `0 @ y <=> x` if the selected candidate is a synthesized candidate with reversed order of parameters, or `x <=> y @ 0` otherwise, using the selected `operator<=>` candidate.
- <sup>9</sup> If a built-in candidate is selected by overload resolution, the operands of class type are converted to the types of the corresponding parameters of the selected operation function, except that the second standard conversion sequence of a user-defined conversion sequence (??) is not applied. Then the operator is treated as the corresponding built-in operator and interpreted according to ??.
- [*Example:*

```
struct X {
    operator double();
};

struct Y {
    operator int*();
};

int *a = Y() + 100.0;           // error: pointer arithmetic requires integral operand
int *b = Y() + X();            // error: pointer arithmetic requires integral operand
— end example]
```

- <sup>10</sup> The second operand of operator `->` is ignored in selecting an `operator->` function, and is not an argument when the `operator->` function is called. When `operator->` returns, the operator `->` is applied to the value returned, with the original second operand.<sup>130</sup>
- <sup>11</sup> If the operator is the operator `,`, the unary operator `&`, or the operator `->`, and there are no viable functions, then the operator is assumed to be the built-in operator and interpreted according to ??.
- <sup>12</sup> [*Note:* The lookup rules for operators in expressions are different than the lookup rules for operator function names in a function call, as shown in the following example:

```
struct A { };
void operator + (A, A);

struct B {
    void operator + (B);
    void f ();
};

A a;

void B::f() {
    operator+ (a,a);           // error: global operator hidden by member
    a + a;                    // OK: calls global operator+
}

— end note]
```

### 16.3.1.3 Initialization by constructor

[`over.match.ctor`]

- <sup>1</sup> When objects of class type are direct-initialized (??), copy-initialized from an expression of the same or a derived class type (??), or default-initialized (??), overload resolution selects the constructor. For direct-

<sup>130</sup> If the value returned by the `operator->` function has class type, this may result in selecting and calling another `operator->` function. The process repeats until an `operator->` function returns a value of non-class type.

initialization or default-initialization that is not in the context of copy-initialization, the candidate functions are all the constructors of the class of the object being initialized. For copy-initialization, the candidate functions are all the converting constructors (??) of that class. The argument list is the *expression-list* or *assignment-expression* of the *initializer*.

#### 16.3.1.4 Copy-initialization of class by user-defined conversion

[**over.match.copy**]

- <sup>1</sup> Under the conditions specified in ??, as part of a copy-initialization of an object of class type, a user-defined conversion can be invoked to convert an initializer expression to the type of the object being initialized. Overload resolution is used to select the user-defined conversion to be invoked. [ *Note:* The conversion performed for indirect binding to a reference to a possibly cv-qualified class type is determined in terms of a corresponding non-reference copy-initialization. — *end note* ] Assuming that “cv1 T” is the type of the object being initialized, with T a class type, the candidate functions are selected as follows:
  - (1.1) — The converting constructors (??) of T are candidate functions.
  - (1.2) — When the type of the initializer expression is a class type “cv S”, the non-explicit conversion functions of S and its base classes are considered. When initializing a temporary object (??) to be bound to the first parameter of a constructor where the parameter is of type “reference to possibly cv-qualified T” and the constructor is called with a single argument in the context of direct-initialization of an object of type “cv2 T”, explicit conversion functions are also considered. Those that are not hidden within S and yield a type whose cv-unqualified version is the same type as T or is a derived class thereof are candidate functions. Conversion functions that return “reference to X” return lvalues or xvalues, depending on the type of reference, of type X and are therefore considered to yield X for this process of selecting candidate functions.
- <sup>2</sup> In both cases, the argument list has one argument, which is the initializer expression. [ *Note:* This argument will be compared against the first parameter of the constructors and against the implicit object parameter of the conversion functions. — *end note* ]

#### 16.3.1.5 Initialization by conversion function

[**over.match.conv**]

- <sup>1</sup> Under the conditions specified in ??, as part of an initialization of an object of non-class type, a conversion function can be invoked to convert an initializer expression of class type to the type of the object being initialized. Overload resolution is used to select the conversion function to be invoked. Assuming that “cv1 T” is the type of the object being initialized, and “cv S” is the type of the initializer expression, with S a class type, the candidate functions are selected as follows:
  - (1.1) — The conversion functions of S and its base classes are considered. Those non-explicit conversion functions that are not hidden within S and yield type T or a type that can be converted to type T via a standard conversion sequence (??) are candidate functions. For direct-initialization, those explicit conversion functions that are not hidden within S and yield type T or a type that can be converted to type T with a qualification conversion (??) are also candidate functions. Conversion functions that return a cv-qualified type are considered to yield the cv-unqualified version of that type for this process of selecting candidate functions. Conversion functions that return “reference to cv2 X” return lvalues or xvalues, depending on the type of reference, of type “cv2 X” and are therefore considered to yield X for this process of selecting candidate functions.
- <sup>2</sup> The argument list has one argument, which is the initializer expression. [ *Note:* This argument will be compared against the implicit object parameter of the conversion functions. — *end note* ]

### 16.3.1.6 Initialization by conversion function for direct reference binding [over.match.ref]

- <sup>1</sup> Under the conditions specified in ??, a reference can be bound directly to a glvalue or class prvalue that is the result of applying a conversion function to an initializer expression. Overload resolution is used to select the conversion function to be invoked. Assuming that “reference to *cv1 T*” is the type of the reference being initialized, and “*cv S*” is the type of the initializer expression, with *S* a class type, the candidate functions are selected as follows:
  - (1.1) — The conversion functions of *S* and its base classes are considered. Those non-explicit conversion functions that are not hidden within *S* and yield type “lvalue reference to *cv2 T2*” (when initializing an lvalue reference or an rvalue reference to function) or “*cv2 T2*” or “rvalue reference to *cv2 T2*” (when initializing an rvalue reference or an lvalue reference to function), where “*cv1 T*” is reference-compatible (??) with “*cv2 T2*”, are candidate functions. For direct-initialization, those explicit conversion functions that are not hidden within *S* and yield type “lvalue reference to *cv2 T2*” or “*cv2 T2*” or “rvalue reference to *cv2 T2*”, respectively, where *T2* is the same type as *T* or can be converted to type *T* with a qualification conversion (??), are also candidate functions.
- 2 The argument list has one argument, which is the initializer expression. [ *Note:* This argument will be compared against the implicit object parameter of the conversion functions. — end note ]

### 16.3.1.7 Initialization by list-initialization

[over.match.list]

- <sup>1</sup> When objects of non-aggregate class type *T* are list-initialized such that ?? specifies that overload resolution is performed according to the rules in this subclause, overload resolution selects the constructor in two phases:
  - (1.1) — Initially, the candidate functions are the initializer-list constructors (??) of the class *T* and the argument list consists of the initializer list as a single argument.
  - (1.2) — If no viable initializer-list constructor is found, overload resolution is performed again, where the candidate functions are all the constructors of the class *T* and the argument list consists of the elements of the initializer list.

If the initializer list has no elements and *T* has a default constructor, the first phase is omitted. In copy-list-initialization, if an explicit constructor is chosen, the initialization is ill-formed. [ *Note:* This differs from other situations (??, ??), where only converting constructors are considered for copy-initialization. This restriction only applies if this initialization is part of the final result of overload resolution. — end note ]

### 16.3.1.8 Class template argument deduction

[over.match.class.deduct]

- <sup>1</sup> When resolving a placeholder for a deduced class type (??) where the *template-name* names a primary class template *C*, a set of functions and function templates is formed comprising:
  - (1.1) — If *C* is defined, for each constructor of *C*, a function template with the following properties:
    - (1.1.1) — The template parameters are the template parameters of *C* followed by the template parameters (including default template arguments) of the constructor, if any.
    - (1.1.2) — The types of the function parameters are those of the constructor.
    - (1.1.3) — The return type is the class template specialization designated by *C* and template arguments corresponding to the template parameters of *C*.
  - (1.2) — If *C* is not defined or does not declare any constructors, an additional function template derived as above from a hypothetical constructor *C()*.
  - (1.3) — An additional function template derived as above from a hypothetical constructor *C(C)*, called the *copy deduction candidate*.

- (1.4) — For each *deduction-guide*, a function or function template with the following properties:
- (1.4.1) — The template parameters, if any, and function parameters are those of the *deduction-guide*.
- (1.4.2) — The return type is the *simple-template-id* of the *deduction-guide*.
- 2 Initialization and overload resolution are performed as described in ?? and ??, ??, or ?? (as appropriate for the type of initialization performed) for an object of a hypothetical class type, where the selected functions and function templates are considered to be the constructors of that class type for the purpose of forming an overload set, and the initializer is provided by the context in which class template argument deduction was performed. As an exception, the first phase in ?? (considering initializer-list constructors) is omitted if the initializer list consists of a single expression of type *cv U*, where *U* is a specialization of *C* or a class derived from a specialization of *C*. Each such notional constructor is considered to be explicit if the function or function template was generated from a constructor or *deduction-guide* that was declared **explicit**. All such notional constructors are considered to be public members of the hypothetical class type.

3 [Example:

```
template <class T> struct A {
    explicit A(const T&, ...) noexcept;                                // #1
    A(T&&, ...);                                                       // #2
};

int i;
A a1 = { i, i };      // error: explicit constructor #1 selected in copy-list-initialization during deduction,
                      // cannot deduce from non-forwarding rvalue reference in #2

A a2{i, i};          // OK, #1 deduces to A<int> and also initializes
A a3{0, i};           // OK, #2 deduces to A<int> and also initializes
A a4 = {0, i};         // OK, #2 deduces to A<int> and also initializes

template <class T> A(const T&, const T&) -> A<T&>; // #3
template <class T> explicit A(T&&, T&&) -> A<T>;     // #4

A a5 = {0, 1};        // error: explicit deduction guide #4 selected in copy-list-initialization during deduction
A a6{0,1};            // OK, #4 deduces to A<int> and #2 initializes
A a7 = {0, i};         // error: #3 deduces to A<int&>, #1 and #2 declare same constructor
A a8{0,i};             // error: #3 deduces to A<int&>, #1 and #2 declare same constructor

template <class T> struct B {
    template <class U> using TA = T;
    template <class U> B(U, TA<U>);
};

B b{(int*)0, (char*)0}; // OK, deduces B<char*>

— end example]
```

### 16.3.2 Viable functions

[**over.match.viable**]

- <sup>1</sup> From the set of candidate functions constructed for a given context (??), a set of viable functions is chosen, from which the best function will be selected by comparing argument conversion sequences and associated constraints (??) for the best fit (??). The selection of viable functions considers associated constraints, if

any, and relationships between arguments and function parameters other than the ranking of conversion sequences.

- 2 First, to be a viable function, a candidate function shall have enough parameters to agree in number with the arguments in the list.
  - (2.1) — If there are  $m$  arguments in the list, all candidate functions having exactly  $m$  parameters are viable.
  - (2.2) — A candidate function having fewer than  $m$  parameters is viable only if it has an ellipsis in its parameter list (??). For the purposes of overload resolution, any argument for which there is no corresponding parameter is considered to “match the ellipsis” (??).
  - (2.3) — A candidate function having more than  $m$  parameters is viable only if the  $(m+1)$ -st parameter has a default argument (??).<sup>131</sup> For the purposes of overload resolution, the parameter list is truncated on the right, so that there are exactly  $m$  parameters.
- 3 Second, for a function to be viable, if it has associated constraints, those constraints shall be satisfied (??).
- 4 Third, for  $F$  to be a viable function, there shall exist for each argument an *implicit conversion sequence* (??) that converts that argument to the corresponding parameter of  $F$ . If the parameter has reference type, the implicit conversion sequence includes the operation of binding the reference, and the fact that an lvalue reference to non-const cannot be bound to an rvalue and that an rvalue reference cannot be bound to an lvalue can affect the viability of the function (see ??).

### 16.3.3 Best viable function

[over.match.best]

- 1 Define  $\text{ICS}_i(F)$  as follows:

- (1.1) — If  $F$  is a static member function,  $\text{ICS}_1(F)$  is defined such that  $\text{ICS}_1(F)$  is neither better nor worse than  $\text{ICS}_1(G)$  for any function  $G$ , and, symmetrically,  $\text{ICS}_1(G)$  is neither better nor worse than  $\text{ICS}_1(F)$ ;<sup>132</sup> otherwise,
- (1.2) — let  $\text{ICS}_i(F)$  denote the implicit conversion sequence that converts the  $i$ -th argument in the list to the type of the  $i$ -th parameter of viable function  $F$ . ?? defines the implicit conversion sequences and ?? defines what it means for one implicit conversion sequence to be a better conversion sequence or worse conversion sequence than another.

Given these definitions, a viable function  $F_1$  is defined to be a *better* function than another viable function  $F_2$  if for all arguments  $i$ ,  $\text{ICS}_i(F_1)$  is not a worse conversion sequence than  $\text{ICS}_i(F_2)$ , and then

- (1.3) — for some argument  $j$ ,  $\text{ICS}_j(F_1)$  is a better conversion sequence than  $\text{ICS}_j(F_2)$ , or, if not that,
- (1.4) — the context is an initialization by user-defined conversion (see ??, ??, and ??) and the standard conversion sequence from the return type of  $F_1$  to the destination type (i.e., the type of the entity being initialized) is a better conversion sequence than the standard conversion sequence from the return type of  $F_2$  to the destination type [*Example*:

```
struct A {
    A();
    operator int();
    operator double();
} a;
int i = a;           // a.operator int() followed by no conversion is better than
```

<sup>131</sup>) According to ??, parameters following the  $(m+1)$ -st parameter must also have default arguments.

<sup>132</sup>) If a function is a static member function, this definition means that the first argument, the implied object argument, has no effect in the determination of whether the function is better or worse than any other function.

```
// a.operator double() followed by a conversion to int
float x = a;           // ambiguous: both possibilities require conversions,
                       // and neither is better than the other
```

— end example] or, if not that,

- (1.5) — the context is an initialization by conversion function for direct reference binding (??) of a reference to function type, the return type of F1 is the same kind of reference (lvalue or rvalue) as the reference being initialized, and the return type of F2 is not [ Example:

```
template <class T> struct A {
    operator T&();      // #1
    operator T&&();     // #2
};

typedef int Fn();
A<Fn> a;
Fn& lf = a;           // calls #1
Fn&& rf = a;         // calls #2
```

— end example] or, if not that,

- (1.6) — F1 is not a function template specialization and F2 is a function template specialization, or, if not that,

- (1.7) — F1 and F2 are function template specializations, and the function template for F1 is more specialized than the template for F2 according to the partial ordering rules described in ??, or, if not that,

- (1.8) — F1 and F2 are non-template functions with the same parameter-type-lists, and F1 is more constrained than F2 according to the partial ordering of constraints described in ??, or if not that,

- (1.9) — F1 is a constructor for a class D, F2 is a constructor for a base class B of D, and for all arguments the corresponding parameters of F1 and F2 have the same type. [ Example:

```
struct A {
    A(int = 0);
};

struct B: A {
    using A::A;
    B();
};

int main() {
    B b;           // OK, B::B()
}
```

— end example] or, if not that,

- (1.10) — F1 is an operator function for a relational (??) or equality (??) operator and F2 is an operator function for a three-way comparison operator (??) [ Example:

```
struct S {
    auto operator<=(const S&, const S&) = default; // #1
    bool operator<(const S&, const S&);             // #2
};

bool b = S() < S();           // calls #2
```

— end example] or, if not that,

- (1.11) — F1 and F2 are operator functions for `operator<=>` and F2 is a synthesized candidate with reversed order of parameters and F1 is not [ *Example*:

```
struct S {
    std::weak_ordering operator<=>(const S&, int); // #1
    std::weak_ordering operator<=>(int, const S&); // #2
};

bool b = 1 < S(); // calls #2
```

— *end example*] or, if not that

- (1.12) — F1 is generated from a *deduction-guide* (??) and F2 is not, or, if not that,

- (1.13) — F1 is the copy deduction candidate (??) and F2 is not, or, if not that,

- (1.14) — F1 is generated from a non-template constructor and F2 is generated from a constructor template.

[ *Example*:

```
template <class T> struct A {
    using value_type = T;
    A(value_type); // #1
    A(const A&); // #2
    A(T, T, int); // #3
    template<class U>
        A(int, T, U); // #4
    // #5 is the copy deduction candidate, A(A)
};

A x(1, 2, 3); // uses #3, generated from a non-template constructor

template <class T>
A(T) -> A<T>; // #6, less specialized than #5

A a(42); // uses #6 to deduce A<int> and #1 to initialize
A b = a; // uses #5 to deduce A<int> and #2 to initialize

template <class T>
A(A<T>) -> A<A<T>>; // #7, as specialized as #5

A b2 = a; // uses #7 to deduce A<A<int>> and #1 to initialize
```

— *end example*]

- <sup>2</sup> If there is exactly one viable function that is a better function than all other viable functions, then it is the one selected by overload resolution; otherwise the call is ill-formed.<sup>133</sup> [ *Example*:

```
void Fcn(const int*, short);
void Fcn(int*, int);

int i;
short s = 0;
```

<sup>133</sup>) The algorithm for selecting the best viable function is linear in the number of viable functions. Run a simple tournament to find a function W that is not worse than any opponent it faced. Although another function F that W did not face might be at least as good as W, F cannot be the best function because at some point in the tournament F encountered another function G such that F was not better than G. Hence, W is either the best function or there is no best function. So, make a second pass over the viable functions to verify that W is better than all other functions.

```

void f() {
    Fcn(&i, s);           // is ambiguous because &i → int* is better than &i → const int*
                           // but s → short is also better than s → int

    Fcn(&i, 1L);          // calls Fcn(int*, int), because &i → int* is better than &i → const int*
                           // and 1L → short and 1L → int are indistinguishable

    Fcn(&i, 'c');         // calls Fcn(int*, int), because &i → int* is better than &i → const int*
                           // and c → int is better than c → short
}

— end example]

```

- <sup>3</sup> If the best viable function resolves to a function for which multiple declarations were found, and if at least two of these declarations — or the declarations they refer to in the case of *using-declarations* — specify a default argument that made the function viable, the program is ill-formed. [Example:

```

namespace A {
    extern "C" void f(int = 5);
}

namespace B {
    extern "C" void f(int = 5);
}

using A::f;
using B::f;

void use() {
    f(3);                // OK, default argument was not used for viability
    f();                 // error: found default argument twice
}

```

— end example]

### 16.3.3.1 Implicit conversion sequences

[over.best.ics]

- <sup>1</sup> An *implicit conversion sequence* is a sequence of conversions used to convert an argument in a function call to the type of the corresponding parameter of the function being called. The sequence of conversions is an implicit conversion as defined in ??, which means it is governed by the rules for initialization of an object or reference by a single expression (??, ??).
- <sup>2</sup> Implicit conversion sequences are concerned only with the type, cv-qualification, and value category of the argument and how these are converted to match the corresponding properties of the parameter. Other properties, such as the lifetime, storage class, alignment, accessibility of the argument, whether the argument is a bit-field, and whether a function is deleted (??), are ignored. So, although an implicit conversion sequence can be defined for a given argument-parameter pair, the conversion from the argument to the parameter might still be ill-formed in the final analysis.
- <sup>3</sup> A well-formed implicit conversion sequence is one of the following forms:

- (3.1) — a *standard conversion sequence* (??),
- (3.2) — a *user-defined conversion sequence* (??), or
- (3.3) — an *ellipsis conversion sequence* (??).

<sup>4</sup> However, if the target is

- (4.1) — the first parameter of a constructor or
- (4.2) — the implicit object parameter of a user-defined conversion function

and the constructor or user-defined conversion function is a candidate by

- (4.3) — ??, when the argument is the temporary in the second step of a class copy-initialization,
- (4.4) — ??, ??, or ?? (in all cases), or
- (4.5) — the second phase of ?? when the initializer list has exactly one element that is itself an initializer list, and the target is the first parameter of a constructor of class X, and the conversion is to X or reference to cv X,

user-defined conversion sequences are not considered. [ *Note:* These rules prevent more than one user-defined conversion from being applied during overload resolution, thereby avoiding infinite recursion. — *end note* ]

[ *Example:*

```
struct Y { Y(int); };
struct A { operator int(); };
Y y1 = A();           // error: A::operator int() is not a candidate

struct X {};
struct B { operator X(); };
B b;
X x({b});           // error: B::operator X() is not a candidate
```

— *end example* ]

<sup>5</sup> For the case where the parameter type is a reference, see ??.

<sup>6</sup> When the parameter type is not a reference, the implicit conversion sequence models a copy-initialization of the parameter from the argument expression. The implicit conversion sequence is the one required to convert the argument expression to a prvalue of the type of the parameter. [ *Note:* When the parameter has a class type, this is a conceptual conversion defined for the purposes of ??; the actual initialization is defined in terms of constructors and is not a conversion. — *end note* ] Any difference in top-level cv-qualification is subsumed by the initialization itself and does not constitute a conversion. [ *Example:* A parameter of type A can be initialized from an argument of type const A. The implicit conversion sequence for that case is the identity sequence; it contains no “conversion” from const A to A. — *end example* ] When the parameter has a class type and the argument expression has the same type, the implicit conversion sequence is an identity conversion. When the parameter has a class type and the argument expression has a derived class type, the implicit conversion sequence is a derived-to-base Conversion from the derived class to the base class. [ *Note:* There is no such standard conversion; this derived-to-base Conversion exists only in the description of implicit conversion sequences. — *end note* ] A derived-to-base Conversion has Conversion rank (??).

- <sup>7</sup> In all contexts, when converting to the implicit object parameter or when converting to the left operand of an assignment operation only standard conversion sequences are allowed.
- <sup>8</sup> If no conversions are required to match an argument to a parameter type, the implicit conversion sequence is the standard conversion sequence consisting of the identity conversion (??).
- <sup>9</sup> If no sequence of conversions can be found to convert an argument to a parameter type, an implicit conversion sequence cannot be formed.

- <sup>10</sup> If several different sequences of conversions exist that each convert the argument to the parameter type, the implicit conversion sequence associated with the parameter is defined to be the unique conversion sequence designated the *ambiguous conversion sequence*. For the purpose of ranking implicit conversion sequences as described in ??, the ambiguous conversion sequence is treated as a user-defined conversion sequence that is indistinguishable from any other user-defined conversion sequence. [ *Note:* This rule prevents a function from becoming non-viable because of an ambiguous conversion sequence for one of its parameters. [ *Example:*

```

class B;
class A { A (B&); };
class B { operator A () ; };
class C { C (B&); };
void f(A) { }
void f(C) { }
B b;
f(b);           // ill-formed: ambiguous because there is a conversion b → C (via constructor)
                // and an (ambiguous) conversion b → A (via constructor or conversion function)
void f(B) { }
f(b);           // OK, unambiguous

```

— end example] — end note] If a function that uses the ambiguous conversion sequence is selected as the best viable function, the call will be ill-formed because the conversion of one of the arguments in the call is ambiguous.

- <sup>11</sup> The three forms of implicit conversion sequences mentioned above are defined in the following subclauses.

#### 16.3.3.1.1 Standard conversion sequences

[over.ics.scs]

- <sup>1</sup> Table ?? summarizes the conversions defined in ?? and partitions them into four disjoint categories: Lvalue Transformation, Qualification Adjustment, Promotion, and Conversion. [ *Note:* These categories are orthogonal with respect to value category, cv-qualification, and data representation: the Lvalue Transformations do not change the cv-qualification or data representation of the type; the Qualification Adjustments do not change the value category or data representation of the type; and the Promotions and Conversions do not change the value category or cv-qualification of the type. — end note]
- <sup>2</sup> [ *Note:* As described in ??, a standard conversion sequence is either the Identity conversion by itself (that is, no conversion) or consists of one to three conversions from the other four categories. If there are two or more conversions in the sequence, the conversions are applied in the canonical order: **Lvalue Transformation, Promotion or Conversion, Qualification Adjustment.** — end note]
- <sup>3</sup> Each conversion in Table ?? also has an associated rank (Exact Match, Promotion, or Conversion). These are used to rank standard conversion sequences (??). The rank of a conversion sequence is determined by considering the rank of each conversion in the sequence and the rank of any reference binding (??). If any of those has Conversion rank, the sequence has Conversion rank; otherwise, if any of those has Promotion rank, the sequence has Promotion rank; otherwise, the sequence has Exact Match rank.

#### 16.3.3.1.2 User-defined conversion sequences

[over.ics.user]

- A user-defined conversion sequence consists of an initial standard conversion sequence followed by a user-defined conversion (??) followed by a second standard conversion sequence. If the user-defined conversion is specified by a constructor (??), the initial standard conversion sequence converts the source type to the type required by the argument of the constructor. If the user-defined conversion is specified by a conversion function (??), the initial standard conversion sequence converts the source type to the implicit object parameter of the conversion function.

Table 13 — Conversions

Conversion	Category	Rank	Subclause	
No conversions required	Identity	Exact Match	??	
Lvalue-to-rvalue conversion	Lvalue Transformation		??	
Array-to-pointer conversion			??	
Function-to-pointer conversion			??	
Qualification conversions	Qualification Adjustment		??	
Function pointer conversion			??	
Integral promotions	Promotion	Promotion	??	
Floating-point promotion			??	
Integral conversions	Conversion	Conversion	??	
Floating-point conversions			??	
Floating-integral conversions			??	
Pointer conversions			??	
Pointer-to-member conversions			??	
Boolean conversions			??	

- 2 The second standard conversion sequence converts the result of the user-defined conversion to the target type for the sequence. Since an implicit conversion sequence is an initialization, the special rules for initialization by user-defined conversion apply when selecting the best user-defined conversion for a user-defined conversion sequence (see ?? and ??).
- 3 If the user-defined conversion is specified by a specialization of a conversion function template, the second standard conversion sequence shall have exact match rank.
- 4 A conversion of an expression of class type to the same class type is given Exact Match rank, and a conversion of an expression of class type to a base class of that type is given Conversion rank, in spite of the fact that a constructor (i.e., a user-defined conversion function) is called for those cases.

**16.3.3.1.3 Ellipsis conversion sequences**

[over.ics.ellipsis]

- 1 An ellipsis conversion sequence occurs when an argument in a function call is matched with the ellipsis parameter specification of the function called (see ??).

**16.3.3.1.4 Reference binding**

[over.ics.ref]

- 1 When a parameter of reference type binds directly (??) to an argument expression, the implicit conversion sequence is the identity conversion, unless the argument expression has a type that is a derived class of the parameter type, in which case the implicit conversion sequence is a derived-to-base Conversion (??).  
[Example:

```
struct A {};
struct B : public A {} b;
int f(A&);
int f(B&);
int i = f(b);      // calls f(B&), an exact match, rather than f(A&), a conversion
```

—end example] If the parameter binds directly to the result of applying a conversion function to the argument expression, the implicit conversion sequence is a user-defined conversion sequence (??), with the second standard conversion sequence either an identity conversion or, if the conversion function returns an entity of a type that is a derived class of the parameter type, a derived-to-base Conversion.

- 2 When a parameter of reference type is not bound directly to an argument expression, the conversion sequence is the one required to convert the argument expression to the referenced type according to ?. Conceptually,

this conversion sequence corresponds to copy-initializing a temporary of the referenced type with the argument expression. Any difference in top-level cv-qualification is subsumed by the initialization itself and does not constitute a conversion.

- <sup>3</sup> Except for an implicit object parameter, for which see ??, a standard conversion sequence cannot be formed if it requires binding an lvalue reference other than a reference to a non-volatile **const** type to an rvalue or binding an rvalue reference to an lvalue other than a function lvalue. [ *Note:* This means, for example, that a candidate function cannot be a viable function if it has a non-**const** lvalue reference parameter (other than the implicit object parameter) and the corresponding argument would require a temporary to be created to initialize the lvalue reference (see ??). — *end note* ]
- <sup>4</sup> Other restrictions on binding a reference to a particular argument that are not based on the types of the reference and the argument do not affect the formation of a standard conversion sequence, however. [ *Example:* A function with an “lvalue reference to **int**” parameter can be a viable candidate even if the corresponding argument is an **int** bit-field. The formation of implicit conversion sequences treats the **int** bit-field as an **int** lvalue and finds an exact match with the parameter. If the function is selected by overload resolution, the call will nonetheless be ill-formed because of the prohibition on binding a non-**const** lvalue reference to a bit-field (??). — *end example* ]

#### 16.3.3.1.5 List-initialization sequence

[over.ics.list]

- <sup>1</sup> When an argument is an initializer list (??), it is not an expression and special rules apply for converting it to a parameter type.
- <sup>2</sup> If the initializer list is a *designated-initializer-list*, a conversion is only possible if the parameter has an aggregate type that can be initialized from the initializer list according to the rules for aggregate initialization (??), in which case the implicit conversion sequence is a user-defined conversion sequence whose second standard conversion sequence is an identity conversion. [ *Note:* Aggregate initialization does not require that the members are declared in designation order. If, after overload resolution, the order does not match for the selected overload, the initialization of the parameter will be ill-formed (??). [ *Example:*

```

struct A { int x, y; };
struct B { int y, x; };

void f(A a, int);           // #1
void f(B b, ...);          // #2
void g(A a);               // #3
void g(B b);               // #4
void h() {
    f({.x = 1, .y = 2}, 0); // OK; calls #1
    f({.y = 2, .x = 1}, 0); // error: selects #1, initialization of a fails
                           // due to non-matching member order (??)
    g({.x = 1, .y = 2});   // error: ambiguous between #3 and #4
}

```

— *end example*] — *end note* ]

- <sup>3</sup> Otherwise, if the parameter type is an aggregate class **X** and the initializer list has a single element of type *cv U*, where **U** is **X** or a class derived from **X**, the implicit conversion sequence is the one required to convert the element to the parameter type.
- <sup>4</sup> Otherwise, if the parameter type is a character array<sup>134</sup> and the initializer list has a single element that is an appropriately-typed string literal (??), the implicit conversion sequence is the identity conversion.

<sup>134)</sup> Since there are no parameters of array type, this will only occur as the referenced type of a reference parameter.

- <sup>5</sup> Otherwise, if the parameter type is `std::initializer_list<X>` and all the elements of the initializer list can be implicitly converted to X, the implicit conversion sequence is the worst conversion necessary to convert an element of the list to X, or if the initializer list has no elements, the identity conversion. This conversion can be a user-defined conversion even in the context of a call to an initializer-list constructor. [ *Example*:

```

void f(std::initializer_list<int>);

f( {} );                                // OK: f(initializer_list<int>) identity conversion
f( {1,2,3} );                            // OK: f(initializer_list<int>) identity conversion
f( {'a','b'} );                           // OK: f(initializer_list<int>) integral promotion
f( {1.0} );                              // error: narrowing

struct A {
    A(std::initializer_list<double>);      // #1
    A(std::initializer_list<complex<double>>); // #2
    A(std::initializer_list<std::string>);   // #3
};

A a{ 1.0,2.0 };                         // OK, uses #1

void g(A);
g( { "foo", "bar" } );                  // OK, uses #3

typedef int IA[3];
void h(const IA&);
h( { 1, 2, 3 } );                      // OK: identity conversion
— end example ]

```

- <sup>6</sup> Otherwise, if the parameter type is “array of N X”, if there exists an implicit conversion sequence for each element of the array from the corresponding element of the initializer list (or from {} if there is no such element), the implicit conversion sequence is the worst such implicit conversion sequence.

- <sup>7</sup> Otherwise, if the parameter is a non-aggregate class X and overload resolution per ?? chooses a single best constructor C of X to perform the initialization of an object of type X from the argument initializer list:

- (7.1) — If C is not an initializer-list constructor and the initializer list has a single element of type cv U, where U is X or a class derived from X, the implicit conversion sequence has Exact Match rank if U is X, or Conversion rank if U is derived from X.
- (7.2) — Otherwise, the implicit conversion sequence is a user-defined conversion sequence with the second standard conversion sequence an identity conversion.

If multiple constructors are viable but none is better than the others, the implicit conversion sequence is the ambiguous conversion sequence. User-defined conversions are allowed for conversion of the initializer list elements to the constructor parameter types except as noted in ???. [ *Example*:

```

struct A {
    A(std::initializer_list<int>);
};

void f(A);
f( {'a', 'b'} );                        // OK: f(A(std::initializer_list<int>)) user-defined conversion

struct B {
    B(int, double);
};

§ 16.3.3.1.5

```

```

void g(B);
g( {'a', 'b'} );           // OK: g(B(int, double)) user-defined conversion
g( {1.0, 1.0} );          // error: narrowing

void f(B);
f( {'a', 'b'} );          // error: ambiguous f(A) or f(B)

struct C {
    C(std::string);
};

void h(C);
h({"foo"});               // OK: h(C(std::string("foo")))

struct D {
    D(A, C);
};

void i(D);
i({ {1,2}, {"bar"} });    // OK: i(D(A(std::initializer_list<int>{1,2}), C(std::string("bar"))))

— end example]

```

- <sup>8</sup> Otherwise, if the parameter has an aggregate type which can be initialized from the initializer list according to the rules for aggregate initialization (??), the implicit conversion sequence is a user-defined conversion sequence with the second standard conversion sequence an identity conversion. [ *Example:*

```

struct A {
    int m1;
    double m2;
};

void f(A);
f( {'a', 'b'} );           // OK: f(A(int,double)) user-defined conversion
f( {1.0} );                // error: narrowing

— end example]

```

- <sup>9</sup> Otherwise, if the parameter is a reference, see ???. [ *Note:* The rules in this subclause will apply for initializing the underlying temporary for the reference. — *end note*] [ *Example:*

```

struct A {
    int m1;
    double m2;
};

void f(const A&);
f( {'a', 'b'} );           // OK: f(A(int,double)) user-defined conversion
f( {1.0} );                // error: narrowing

void g(const double &);
g({1});                   // same conversion as int to double

— end example]

```

- <sup>10</sup> Otherwise, if the parameter type is not a class:

- (10.1) — if the initializer list has one element that is not itself an initializer list, the implicit conversion sequence is the one required to convert the element to the parameter type; [ *Example*:

```
void f(int);
f( {'a'} );           // OK: same conversion as char to int
f( {1.0} );          // error: narrowing
— end example]
```

- (10.2) — if the initializer list has no elements, the implicit conversion sequence is the identity conversion. [ *Example*:

```
void f(int);
f( {} );            // OK: identity conversion
— end example]
```

<sup>11</sup> In all cases other than those enumerated above, no conversion is possible.

### 16.3.3.2 Ranking implicit conversion sequences

[over.ics.rank]

- 1 This subclause defines a partial ordering of implicit conversion sequences based on the relationships *better conversion sequence* and *better conversion*. If an implicit conversion sequence S1 is defined by these rules to be a better conversion sequence than S2, then it is also the case that S2 is a *worse conversion sequence* than S1. If conversion sequence S1 is neither better than nor worse than conversion sequence S2, S1 and S2 are said to be *indistinguishable conversion sequences*.

- 2 When comparing the basic forms of implicit conversion sequences (as defined in ??)

- (2.1) — a standard conversion sequence (??) is a better conversion sequence than a user-defined conversion sequence or an ellipsis conversion sequence, and
- (2.2) — a user-defined conversion sequence (??) is a better conversion sequence than an ellipsis conversion sequence (??).

- 3 Two implicit conversion sequences of the same form are indistinguishable conversion sequences unless one of the following rules applies:

- (3.1) — List-initialization sequence L1 is a better conversion sequence than list-initialization sequence L2 if
  - (3.1.1) — L1 converts to `std::initializer_list<X>` for some X and L2 does not, or, if not that,
  - (3.1.2) — L1 converts to type “array of N1 T”, L2 converts to type “array of N2 T”, and N1 is smaller than N2, even if one of the other rules in this paragraph would otherwise apply. [ *Example*:

```
void f1(int);                      // #1
void f1(std::initializer_list<long>); // #2
void g1() { f1({42}); }             // chooses #2

void f2(std::pair<const char*, const char*>); // #3
void f2(std::initializer_list<std::string>); // #4
void g2() { f2({"foo", "bar"}); }       // chooses #4

— end example]
```

- (3.2) — Standard conversion sequence S1 is a better conversion sequence than standard conversion sequence S2 if

- (3.2.1) —  $S_1$  is a proper subsequence of  $S_2$  (comparing the conversion sequences in the canonical form defined by ??, excluding any Lvalue Transformation; the identity conversion sequence is considered to be a subsequence of any non-identity conversion sequence) or, if not that,
- (3.2.2) — the rank of  $S_1$  is better than the rank of  $S_2$ , or  $S_1$  and  $S_2$  have the same rank and are distinguishable by the rules in the paragraph below, or, if not that,
- (3.2.3) —  $S_1$  and  $S_2$  are reference bindings (??) and neither refers to an implicit object parameter of a non-static member function declared without a *ref-qualifier*, and  $S_1$  binds an rvalue reference to an rvalue and  $S_2$  binds an lvalue reference [*Example*:

```

int i;
int f1();
int&& f2();
int g(const int&);
int g(const int&&);

int j = g(i);           // calls g(const int&)
int k = g(f1());        // calls g(const int&&)
int l = g(f2());        // calls g(const int&&)

struct A {
    A& operator<<(int);
    void p() &;
    void p() &&;
};

A& operator<<(A&&, char);
A() << 1;               // calls A::operator<<(int)
A() << 'c';             // calls operator<<(A&&, char)
A a;
a << 1;                 // calls A::operator<<(int)
a << 'c';               // calls A::operator<<(int)
A().p();                 // calls A::p()&&
a.p();                  // calls A::p()&

```

— *end example*] or, if not that,

- (3.2.4) —  $S_1$  and  $S_2$  are reference bindings (??) and  $S_1$  binds an lvalue reference to a function lvalue and  $S_2$  binds an rvalue reference to a function lvalue [*Example*:

```

int f(void(&)());
int f(void(&&)());
void g();
int i1 = f(g);          // calls #1

```

— *end example*] or, if not that,

- (3.2.5) —  $S_1$  and  $S_2$  differ only in their qualification conversion and yield similar types  $T_1$  and  $T_2$  (??), respectively, and the cv-qualification signature of type  $T_1$  is a proper subset of the cv-qualification signature of type  $T_2$  [*Example*:

```

int f(const volatile int *);
int f(const int *);
int i;
int j = f(&i);          // calls f(const int*)

```

— end example] or, if not that,

- (3.2.6) — S1 and S2 are reference bindings (??), and the types to which the references refer are the same type except for top-level cv-qualifiers, and the type to which the reference initialized by S2 refers is more cv-qualified than the type to which the reference initialized by S1 refers. [Example:

```

int f(const int &);
int f(int &);

int g(const int &);
int g(int);

int i;
int j = f(i);           // calls f(int &)
int k = g(i);           // ambiguous

struct X {
    void f() const;
    void f();
};

void g(const X& a, X b) {
    a.f();                // calls X::f() const
    b.f();                // calls X::f()
}

```

— end example]

- (3.3) — User-defined conversion sequence U1 is a better conversion sequence than another user-defined conversion sequence U2 if they contain the same user-defined conversion function or constructor or they initialize the same class in an aggregate initialization and in either case the second standard conversion sequence of U1 is better than the second standard conversion sequence of U2. [Example:

```

struct A {
    operator short();
} a;

int f(int);
int f(float);

int i = f(a);           // calls f(int), because short → int is
                        // better than short → float.

```

— end example]

<sup>4</sup> Standard conversion sequences are ordered by their ranks: an Exact Match is a better conversion than a Promotion, which is a better conversion than a Conversion. Two conversion sequences with the same rank are indistinguishable unless one of the following rules applies:

- (4.1) — A conversion that does not convert a pointer, a pointer to member, or `std::nullptr_t` to `bool` is better than one that does.
- (4.2) — A conversion that promotes an enumeration whose underlying type is fixed to its underlying type is better than one that promotes to the promoted underlying type, if the two are different.
- (4.3) — If class B is derived directly or indirectly from class A, conversion of `B*` to `A*` is better than conversion of `B*` to `void*`, and conversion of `A*` to `void*` is better than conversion of `B*` to `void*`.
- (4.4) — If class B is derived directly or indirectly from class A and class C is derived directly or indirectly from B,

(4.4.1) — conversion of C\* to B\* is better than conversion of C\* to A\*, [*Example*:

```
struct A {};
struct B : public A {};
struct C : public B {};
C* pc;
int f(A*);
int f(B*);
int i = f(pc); // calls f(B*)
— end example]
```

(4.4.2) — binding of an expression of type C to a reference to type B is better than binding an expression of type C to a reference to type A,

(4.4.3) — conversion of A::\* to B::\* is better than conversion of A::\* to C::\*,

(4.4.4) — conversion of C to B is better than conversion of C to A,

(4.4.5) — conversion of B\* to A\* is better than conversion of C\* to A\*,

(4.4.6) — binding of an expression of type B to a reference to type A is better than binding an expression of type C to a reference to type A,

(4.4.7) — conversion of B::\* to C::\* is better than conversion of A::\* to C::\*, and

(4.4.8) — conversion of B to A is better than conversion of C to A.

[*Note*: Compared conversion sequences will have different source types only in the context of comparing the second standard conversion sequence of an initialization by user-defined conversion (see ??); in all other contexts, the source types will be the same and the target types will be different. — *end note*]

## 16.4 Address of overloaded function

[over.over]

<sup>1</sup> A use of an overloaded function name without arguments is resolved in certain contexts to a function, a pointer to function or a pointer to member function for a specific function from the overload set. A function template name is considered to name a set of overloaded functions in such contexts. A function with type F is selected for the function type FT of the target type required in the context if F (after possibly applying the function pointer conversion (??)) is identical to FT. [*Note*: That is, the class of which the function is a member is ignored when matching a pointer-to-member-function type. — *end note*] The target can be

- (1.1) — an object or reference being initialized (??, ??, ??),
- (1.2) — the left side of an assignment (??),
- (1.3) — a parameter of a function (??),
- (1.4) — a parameter of a user-defined operator (??),
- (1.5) — the return value of a function, operator function, or conversion (??),
- (1.6) — an explicit type conversion (??, ??, ??), or
- (1.7) — a non-type *template-parameter* (??).

The overloaded function name can be preceded by the & operator. An overloaded function name shall not be used without arguments in contexts other than those listed. [*Note*: Any redundant set of parentheses surrounding the overloaded function name is ignored (??). — *end note*]

<sup>2</sup> If the name is a function template, template argument deduction is done (??), and if the argument deduction succeeds, the resulting template argument list is used to generate a single function template specialization,

which is added to the set of overloaded functions considered. [ *Note:* As described in ??, if deduction fails and the function template name is followed by an explicit template argument list, the *template-id* is then examined to see whether it identifies a single function template specialization. If it does, the *template-id* is considered to be an lvalue for that function template specialization. The target type is not used in that determination. — *end note* ]

- 3 Non-member functions and static member functions match targets of function pointer type or reference to function type. Non-static member functions match targets of pointer-to-member-function type. If a non-static member function is selected, the reference to the overloaded function name is required to have the form of a pointer to member as described in ??.
- 4 All functions with associated constraints that are not satisfied (??) are eliminated from the set of selected functions. If more than one function in the set remains, all function template specializations in the set are eliminated if the set also contains a function that is not a function template specialization. Any given non-template function F0 is eliminated if the set contains a second non-template function that is more constrained than F0 according to the partial ordering rules of ???. Any given function template specialization F1 is eliminated if the set contains a second function template specialization whose function template is more specialized than the function template of F1 according to the partial ordering rules of ???. After such eliminations, if any, there shall remain exactly one selected function.

- 5 [ *Example:*

```

int f(double);
int f(int);
int (*pf)(double) = &f;           // selects f(double)
int (*pfi)(int) = &f;           // selects f(int)
int (*pfe)(...) = &f;           // error: type mismatch
int (&rfi)(int) = f;            // selects f(int)
int (&rfd)(double) = f;           // selects f(double)
void g() {
    (int (*)(int))&f;           // cast expression as selector
}

```

The initialization of pfe is ill-formed because no f() with type int(...) has been declared, and not because of any ambiguity. For another example,

```

struct X {
    int f(int);
    static int f(long);
};

int (X::*p1)(int) = &X::f;        // OK
int     (*p2)(int) = &X::f;        // error: mismatch
int     (*p3)(long) = &X::f;       // OK
int (X::*p4)(long) = &X::f;       // error: mismatch
int (X::*p5)(int) = &(X::f);      // error: wrong syntax for
                                    // pointer to member
int     (*p6)(long) = &(X::f);     // OK

```

— *end example* ]

- 6 [ *Note:* If f() and g() are both overloaded functions, the cross product of possibilities must be considered to resolve f(&g), or the equivalent expression f(g). — *end note* ]

<sup>7</sup> [Note: Even if B is a public base of D, we have

```
D* f();
B* (*p1)() = &f; // error

void g(D*);
void (*p2)(B*) = &g; // error

— end note]
```

## 16.5 Overloaded operators

[over.oper]

- <sup>1</sup> A function declaration having one of the following *operator-function-ids* as its name declares an *operator function*. A function template declaration having one of the following *operator-function-ids* as its name declares an *operator function template*. A specialization of an operator function template is also an operator function. An operator function is said to *implement* the operator named in its *operator-function-id*.

*operator-function-id*:

operator operator

*operator*: one of

new	delete	new[]	delete[] ()	[]	->	->*	~
!	+	-	*	/	%	^	&
=	+=	-=	*=	/=	%=	^=	&=
==	!=	<	>	<=	>=	<=>	&&
<<	>>	<<=	>>=	++	--	,	

[Note: The last two operators are function call (??) and subscripting (??). The operators new[], delete[], (), and [] are formed from more than one token. — end note]

- <sup>2</sup> Both the unary and binary forms of

+ - \* &

can be overloaded.

- <sup>3</sup> The following operators cannot be overloaded:

. .\* :: ?:

nor can the preprocessing symbols # and ## (??).

- <sup>4</sup> Operator functions are usually not called directly; instead they are invoked to evaluate the operators they implement (?? – ??). They can be explicitly called, however, using the *operator-function-id* as the name of the function in the function call syntax (??). [Example:

```
complex z = a.operator+(b); // complex z = a+b;
void* p = operator new(sizeof(int)*n);
```

— end example]

- <sup>5</sup> The allocation and deallocation functions, operator new, operator new[], operator delete and operator delete[], are described completely in ???. The attributes and restrictions found in the rest of this subclause do not apply to them unless explicitly stated in ???.

- <sup>6</sup> An operator function shall either be a non-static member function or be a non-member function that has at least one parameter whose type is a class, a reference to a class, an enumeration, or a reference to an enumeration. It is not possible to change the precedence, grouping, or number of operands of operators. The meaning of the operators =, (unary) &, and , (comma), predefined for each type, can be changed for

specific class and enumeration types by defining operator functions that implement these operators. Operator functions are inherited in the same manner as other base class functions.

- <sup>7</sup> The identities among certain predefined operators applied to basic types (for example, `++a ≡ a+=1`) need not hold for operator functions. Some predefined operators, such as `+=`, require an operand to be an lvalue when applied to basic types; this is not required by operator functions.
- <sup>8</sup> An operator function cannot have default arguments (??), except where explicitly stated below. Operator functions cannot have more or fewer parameters than the number required for the corresponding operator, as described in the rest of this subclause.
- <sup>9</sup> Operators not mentioned explicitly in subclauses ?? through ?? act as ordinary unary and binary operators obeying the rules of ?? or ??.

### 16.5.1 Unary operators

[**over.unary**]

- <sup>1</sup> A prefix unary operator shall be implemented by a non-static member function (??) with no parameters or a non-member function with one parameter. Thus, for any prefix unary operator `@`, `@x` can be interpreted as either `x.operator@()` or `operator@(x)`. If both forms of the operator function have been declared, the rules in ?? determine which, if any, interpretation is used. See ?? for an explanation of the postfix unary operators `++` and `--`.
- <sup>2</sup> The unary and binary forms of the same operator are considered to have the same name. [ *Note:* Consequently, a unary operator can hide a binary operator from an enclosing scope, and vice versa. — *end note* ]

### 16.5.2 Binary operators

[**over.binary**]

- <sup>1</sup> A binary operator shall be implemented either by a non-static member function (??) with one parameter or by a non-member function with two parameters. Thus, for any binary operator `@`, `x@y` can be interpreted as either `x.operator@(y)` or `operator@(x,y)`. If both forms of the operator function have been declared, the rules in ?? determine which, if any, interpretation is used.

### 16.5.3 Assignment

[**over.ass**]

- <sup>1</sup> An assignment operator shall be implemented by a non-static member function with exactly one parameter. Because a copy assignment operator `operator=` is implicitly declared for a class if not declared by the user (??), a base class assignment operator is always hidden by the copy assignment operator of the derived class.
- <sup>2</sup> Any assignment operator, even the copy and move assignment operators, can be virtual. [ *Note:* For a derived class D with a base class B for which a virtual copy/move assignment has been declared, the copy/move assignment operator in D does not override B's virtual copy/move assignment operator. [ *Example:*

```
struct B {
    virtual int operator= (int);
    virtual B& operator= (const B&);
};

struct D : B {
    virtual int operator= (int);
    virtual D& operator= (const B&);
};

D dobj1;
D dobj2;
```

```
B* bptr = &dobj1;
void f() {
    bptr->operator=(99);           // calls D::operator=(int)
    *bptr = 99;                   // ditto
    bptr->operator=(dobj2);       // calls D::operator=(const B&)
    *bptr = dobj2;                // ditto
    dobj1 = dobj2;                // calls implicitly-declared D::operator=(const D&)
}
— end example] — end note]
```

#### 16.5.4 Function call

[over.call]

- <sup>1</sup> `operator()` shall be a non-static member function with an arbitrary number of parameters. It can have default arguments. It implements the function call syntax

*postfix-expression* ( *expression-list<sub>opt</sub>* )

where the *postfix-expression* evaluates to a class object and the possibly empty *expression-list* matches the parameter list of an `operator()` member function of the class. Thus, a call `x(arg1, ...)` is interpreted as `x.operator()(arg1, ...)` for a class object `x` of type `T` if `T::operator()(T1, T2, T3)` exists and if the operator is selected as the best match function by the overload resolution mechanism (??).

#### 16.5.5 Subscripting

[over.sub]

- <sup>1</sup> `operator[]` shall be a non-static member function with exactly one parameter. It implements the subscripting syntax

*postfix-expression* [ *expr-or-braced-init-list* ]

Thus, a subscripting expression `x[y]` is interpreted as `x.operator[](y)` for a class object `x` of type `T` if `T::operator[](T1)` exists and if the operator is selected as the best match function by the overload resolution mechanism (??). [ *Example*:

```
struct X {
    Z operator[](std::initializer_list<int>);
};

X x;
x[{1,2,3}] = 7;           // OK: meaning x.operator[]( {1,2,3} )
int a[10];
a[{1,2,3}] = 7;           // error: built-in subscript operator
— end example]
```

#### 16.5.6 Class member access

[over.ref]

- <sup>1</sup> `operator->` shall be a non-static member function taking no parameters. It implements the class member access syntax that uses `->`.

*postfix-expression* -> *template<sub>opt</sub>* *id-expression*

*postfix-expression* -> *pseudo-destructor-name*

An expression `x->m` is interpreted as `(x.operator->())->m` for a class object `x` of type `T` if `T::operator->()` exists and if the operator is selected as the best match function by the overload resolution mechanism (??).

### 16.5.7 Increment and decrement

[over.inc]

- <sup>1</sup> The user-defined function called `operator++` implements the prefix and postfix `++` operator. If this function is a non-static member function with no parameters, or a non-member function with one parameter, it defines the prefix increment operator `++` for objects of that type. If the function is a non-static member function with one parameter (which shall be of type `int`) or a non-member function with two parameters (the second of which shall be of type `int`), it defines the postfix increment operator `++` for objects of that type. When the postfix increment is called as a result of using the `++` operator, the `int` argument will have value zero.<sup>135</sup>

[*Example:*

```
struct X {
    X& operator++();           // prefix ++a
    X operator++(int);         // postfix a++
};

struct Y { };
Y& operator++(Y&);           // prefix ++b
Y operator++(Y&, int);        // postfix b++

void f(X a, Y b) {
    ++a;                      // a.operator++();
    a++;                      // a.operator++(0);
    ++b;                      // operator++(b);
    b++;                      // operator++(b, 0);

    a.operator++();            // explicit call: like ++a;
    a.operator++(0);           // explicit call: like a++;
    operator++(b);             // explicit call: like ++b;
    operator++(b, 0);          // explicit call: like b++;
}
```

— end example]

- <sup>2</sup> The prefix and postfix decrement operators `--` are handled analogously.

### 16.5.8 User-defined literals

[over.literal]

*literal-operator-id:*

```
operator string-literal identifier
operator user-defined-string-literal
```

- <sup>1</sup> The *string-literal* or *user-defined-string-literal* in a *literal-operator-id* shall have no *encoding-prefix* and shall contain no characters other than the implicit terminating '`\0`'. The *ud-suffix* of the *user-defined-string-literal* or the *identifier* in a *literal-operator-id* is called a *literal suffix identifier*. Some literal suffix identifiers are reserved for future standardization; see [??](#). A declaration whose *literal-operator-id* uses such a literal suffix identifier is ill-formed, no diagnostic required.
- <sup>2</sup> A declaration whose *declarator-id* is a *literal-operator-id* shall be a declaration of a namespace-scope function or function template (it could be a friend function [\(??\)](#)), an explicit instantiation or specialization of a function template, or a *using-declaration* [\(??\)](#). A function declared with a *literal-operator-id* is a *literal operator*. A function template declared with a *literal-operator-id* is a *literal operator template*.

---

<sup>135</sup>) Calling `operator++` explicitly, as in expressions like `a.operator++(2)`, has no special properties: The argument to `operator++` is 2.

- <sup>3</sup> The declaration of a literal operator shall have a *parameter-declaration-clause* equivalent to one of the following:

```
const char*
unsigned long long int
long double
char
wchar_t
char16_t
char32_t
const char*, std::size_t
const wchar_t*, std::size_t
const char16_t*, std::size_t
const char32_t*, std::size_t
```

If a parameter has a default argument (??), the program is ill-formed.

- <sup>4</sup> A *raw literal operator* is a literal operator with a single parameter whose type is `const char*`.
- <sup>5</sup> The declaration of a literal operator template shall have an empty *parameter-declaration-clause* and its *template-parameter-list* shall have a single *template-parameter* that is a non-type template parameter pack (??) with element type `char`.
- <sup>6</sup> Literal operators and literal operator templates shall not have C language linkage.
- <sup>7</sup> [ *Note*: Literal operators and literal operator templates are usually invoked implicitly through user-defined literals (??). However, except for the constraints described above, they are ordinary namespace-scope functions and function templates. In particular, they are looked up like ordinary functions and function templates and they follow the same overload resolution rules. Also, they can be declared `inline` or `constexpr`, they may have internal or external linkage, they can be called explicitly, their addresses can be taken, etc. — *end note* ]

- <sup>8</sup> [ *Example*:

```
void operator "" _km(long double);           // OK
string operator "" _i18n(const char*, std::size_t); // OK
template <char...> double operator "" _\u03c0();    // OK: UCN for lowercase pi
float operator "" _e(const char*);           // OK
float operator "" E(const char*);            // error: reserved literal suffix (??, ??)
double operator "" _Bq(long double);         // OK: does not use the reserved identifier _Bq (??)
double operator "" "" _Bq(long double);       // uses the reserved identifier _Bq (??)
float operator "" " B(const char*);          // error: non-empty string-literal
string operator "" 5X(const char*, std::size_t); // error: invalid literal suffix identifier
double operator "" _miles(double);            // error: invalid parameter-declaration-clause
template <char...> int operator "" _j(const char*); // error: invalid parameter-declaration-clause
extern "C" void operator "" _m(long double);   // error: C language linkage
```

— *end example* ]

## 16.6 Built-in operators

[**over.built**]

- <sup>1</sup> The candidate operator functions that represent the built-in operators defined in ?? are specified in this subclause. These candidate functions participate in the operator overload resolution process as described in ?? and are used for no other purpose. [ *Note*: Because built-in operators take only operands with non-class type, and operator overload resolution occurs only when an operand expression originally has class or enumeration

type, operator overload resolution can resolve to a built-in operator only when an operand has a class type that has a user-defined conversion to a non-class type appropriate for the operator, or when an operand has an enumeration type that can be converted to a type appropriate for the operator. Also note that some of the candidate operator functions given in this subclause are more permissive than the built-in operators themselves. As described in ??, after a built-in operator is selected by overload resolution the expression is subject to the requirements for the built-in operator given in ??, and therefore to any additional semantic constraints given there. If there is a user-written candidate with the same name and parameter types as a built-in candidate operator function, the built-in operator function is hidden and is not included in the set of candidate functions. — *end note*]

- 2 In this subclause, the term *promoted integral type* is used to refer to those integral types which are preserved by integral promotion (??) (including e.g. `int` and `long` but excluding e.g. `char`). Similarly, the term *promoted arithmetic type* refers to floating types plus promoted integral types. [ *Note:* In all cases where a promoted integral type or promoted arithmetic type is required, an operand of enumeration type will be acceptable by way of the integral promotions. — *end note* ]
- 3 In the remainder of this subclause, *vq* represents either `volatile` or no cv-qualifier.
- 4 For every pair (*T*, *vq*), where *T* is an arithmetic type other than `bool`, there exist candidate operator functions of the form

```
vq T& operator++(vq T&);
T operator++(vq T&, int);
```

- 5 For every pair (*T*, *vq*), where *T* is an arithmetic type other than `bool`, there exist candidate operator functions of the form

```
vq T& operator--(vq T&);
T operator--(vq T&, int);
```

- 6 For every pair (*T*, *vq*), where *T* is a cv-qualified or cv-unqualified object type, there exist candidate operator functions of the form

```
T*vq& operator++(T*vq&);
T*vq& operator--(T*vq&);
T* operator++(T*vq&, int);
T* operator--(T*vq&, int);
```

- 7 For every cv-qualified or cv-unqualified object type *T*, there exist candidate operator functions of the form

```
T& operator*(T*);
```

- 8 For every function type *T* that does not have cv-qualifiers or a *ref-qualifier*, there exist candidate operator functions of the form

```
T& operator*(T*);
```

- 9 For every type *T* there exist candidate operator functions of the form

```
T* operator+(T*);
```

- 10 For every promoted arithmetic type *T*, there exist candidate operator functions of the form

```
T operator+(T);
T operator-(T);
```

- 11 For every promoted integral type *T*, there exist candidate operator functions of the form

```
T operator~(T);
```

- <sup>12</sup> For every quintuple ( $C1$ ,  $C2$ ,  $T$ ,  $cv1$ ,  $cv2$ ), where  $C2$  is a class type,  $C1$  is the same type as  $C2$  or is a derived class of  $C2$ , and  $T$  is an object type or a function type, there exist candidate operator functions of the form

```
cv12 T& operator->*(cv1 C1*, cv2 T C2::*);
```

where  $cv12$  is the union of  $cv1$  and  $cv2$ . The return type is shown for exposition only; see ?? for the determination of the operator's result type.

- <sup>13</sup> For every pair of promoted arithmetic types  $L$  and  $R$ , there exist candidate operator functions of the form

```
LR      operator*(L, R);
LR      operator/(L, R);
LR      operator+(L, R);
LR      operator-(L, R);
bool   operator<(L, R);
bool   operator>(L, R);
bool   operator<=(L, R);
bool   operator>=(L, R);
bool   operator==(L, R);
bool   operator!=(L, R);
```

where  $LR$  is the result of the usual arithmetic conversions (??) between types  $L$  and  $R$ .

- <sup>14</sup> For every integral type  $T$  there exists a candidate operator function of the form

```
std::strong_ordering operator<=>(T, T);
```

- <sup>15</sup> For every pair of floating-point types  $L$  and  $R$ , there exists a candidate operator function of the form

```
std::partial_ordering operator<=>(L, R);
```

- <sup>16</sup> For every cv-qualified or cv-unqualified object type  $T$  there exist candidate operator functions of the form

```
T*      operator+(T*, std::ptrdiff_t);
T&      operator[](T*, std::ptrdiff_t);
T*      operator-(T*, std::ptrdiff_t);
T*      operator+(std::ptrdiff_t, T*);
T&      operator[](std::ptrdiff_t, T*);
```

- <sup>17</sup> For every  $T$ , where  $T$  is a pointer to object type, there exist candidate operator functions of the form

```
std::ptrdiff_t operator-(T, T);
```

- <sup>18</sup> For every  $T$ , where  $T$  is an enumeration type or a pointer type, there exist candidate operator functions of the form

```
bool   operator<(T, T);
bool   operator>(T, T);
bool   operator<=(T, T);
bool   operator>=(T, T);
bool   operator==(T, T);
bool   operator!=(T, T);
R      operator<=>(T, T);
```

where  $R$  is the result type specified in ??.

- <sup>19</sup> For every  $T$ , where  $T$  is a pointer-to-member type or `std::nullptr_t`, there exist candidate operator functions of the form

```
bool      operator==(T, T);
bool      operator!=(T, T);
```

```
std::strong_equality operator<=>(T, T);
```

- 20 For every pair of promoted integral types  $L$  and  $R$ , there exist candidate operator functions of the form

```
LR      operator%(L, R);
LR      operator&(L, R);
LR      operator^(L, R);
LR      operator|(L, R);
L       operator<<(L, R);
L       operator>>(L, R);
```

where  $LR$  is the result of the usual arithmetic conversions (??) between types  $L$  and  $R$ .

- 21 For every triple  $(L, vq, R)$ , where  $L$  is an arithmetic type, and  $R$  is a promoted arithmetic type, there exist candidate operator functions of the form

```
vq L&  operator=(vq L&, R);
vq L&  operator*=(vq L&, R);
vq L&  operator/=(vq L&, R);
vq L&  operator+=(vq L&, R);
vq L&  operator-=(vq L&, R);
```

- 22 For every pair  $(T, vq)$ , where  $T$  is any type, there exist candidate operator functions of the form

```
T*vq&  operator=(T*vq&, T*);
```

- 23 For every pair  $(T, vq)$ , where  $T$  is an enumeration or pointer-to-member type, there exist candidate operator functions of the form

```
vq T&  operator=(vq T&, T);
```

- 24 For every pair  $(T, vq)$ , where  $T$  is a cv-qualified or cv-unqualified object type, there exist candidate operator functions of the form

```
T*vq&  operator+=(T*vq&, std::ptrdiff_t);
T*vq&  operator-=(T*vq&, std::ptrdiff_t);
```

- 25 For every triple  $(L, vq, R)$ , where  $L$  is an integral type, and  $R$  is a promoted integral type, there exist candidate operator functions of the form

```
vq L&  operator%=(vq L&, R);
vq L&  operator<=(vq L&, R);
vq L&  operator>=(vq L&, R);
vq L&  operator&=(vq L&, R);
vq L&  operator^=(vq L&, R);
vq L&  operator|=(vq L&, R);
```

- 26 There also exist candidate operator functions of the form

```
bool    operator!(bool);
bool    operator&&(bool, bool);
bool    operator||(bool, bool);
```

- 27 For every pair of promoted arithmetic types  $L$  and  $R$ , there exist candidate operator functions of the form

```
LR      operator?:(bool, L, R);
```

where  $LR$  is the result of the usual arithmetic conversions (??) between types  $L$  and  $R$ . [Note: As with all these descriptions of candidate functions, this declaration serves only to describe the built-in operator for purposes of overload resolution. The operator “?:” cannot be overloaded. —end note]

<sup>28</sup> For every type  $T$ , where  $T$  is a pointer, pointer-to-member, or scoped enumeration type, there exist candidate operator functions of the form

$T$       `operator?:(bool, T, T);`

# 17 Templates

[temp]

- <sup>1</sup> A *template* defines a family of classes, functions, or variables, an alias for a family of types, or a concept.

```

template-declaration:
    template-head declaration
    template-head concept-definition

template-head:
    template < template-parameter-list > requires-clauseopt

template-parameter-list:
    template-parameter
    template-parameter-list , template-parameter

requires-clause:
    requires constraint-logical-or-expression

constraint-logical-or-expression:
    constraint-logical-and-expression
    constraint-logical-or-expression || constraint-logical-and-expression

constraint-logical-and-expression:
    primary-expression
    constraint-logical-and-expression && primary-expression

concept-definition:
    concept concept-name = constraint-expression ;

concept-name:
    identifier

```

[ Note: The > token following the *template-parameter-list* of a *template-declaration* may be the product of replacing a >> token by two consecutive > tokens (??). — end note ]

- <sup>2</sup> The *declaration* in a *template-declaration* (if any) shall

- (2.1) — declare or define a function, a class, or a variable, or
- (2.2) — define a member function, a member class, a member enumeration, or a static data member of a class template or of a class nested within a class template, or
- (2.3) — define a member template of a class or class template, or
- (2.4) — be a *deduction-guide*, or
- (2.5) — be an *alias-declaration*.

- <sup>3</sup> A *template-declaration* is a *declaration*. A *template-declaration* is also a definition if its *template-head* is followed by either a *concept-definition* or a *declaration* that defines a function, a class, a variable, or a static data member. A declaration introduced by a template declaration of a variable is a *variable template*. A variable template at class scope is a *static data member template*.

[ Example:

```

template<class T>
    constexpr T pi = T(3.1415926535897932385L);

```

```

template<class T>
T circular_area(T r) {
    return pi<T> * r * r;
}

struct matrix_constants {
    template<class T>
    using pauli = hermitian_matrix<T, 2>;
    template<class T>
    constexpr pauli<T> sigma1 = { { 0, 1 }, { 1, 0 } };
    template<class T>
    constexpr pauli<T> sigma2 = { { 0, -1i }, { 1i, 0 } };
    template<class T>
    constexpr pauli<T> sigma3 = { { 1, 0 }, { 0, -1 } };
};

— end example]

```

- <sup>4</sup> A *template-declaration* can appear only as a namespace scope or class scope declaration. In a function template declaration, the last component of the *declarator-id* shall not be a *template-id*. [Note: That last component may be an *identifier*, an *operator-function-id*, a *conversion-function-id*, or a *literal-operator-id*. In a class template declaration, if the class name is a *simple-template-id*, the declaration declares a class template partial specialization (??). — end note]
- <sup>5</sup> In a *template-declaration*, explicit specialization, or explicit instantiation the *init-declarator-list* in the declaration shall contain at most one declarator. When such a declaration is used to declare a class template, no declarator is permitted.
- <sup>6</sup> A template name has linkage (??). Specializations (explicit or implicit) of a template that has internal linkage are distinct from all specializations in other translation units. A template, a template explicit specialization (??), and a class template partial specialization shall not have C linkage. Use of a linkage specification other than "C" or "C++" with any of these constructs is conditionally-supported, with implementation-defined semantics. Template definitions shall obey the one-definition rule (??). [Note: Default arguments for function templates and for member functions of class templates are considered definitions for the purpose of template instantiation (??) and must also obey the one-definition rule. — end note]
- <sup>7</sup> A class template shall not have the same name as any other template, class, function, variable, enumeration, enumerator, namespace, or type in the same scope (??), except as specified in ??-. Except that a function template can be overloaded either by non-template functions (??) with the same name or by other function templates with the same name (??), a template name declared in namespace scope or in class scope shall be unique in that scope.
- <sup>8</sup> A *templated entity* is
  - (8.1) — a template,
  - (8.2) — an entity defined (??) or created (??) in a templated entity,
  - (8.3) — a member of a templated entity,
  - (8.4) — an enumerator for an enumeration that is a templated entity, or
  - (8.5) — the closure type of a *lambda-expression* (??) appearing in the declaration of a templated entity.

[Note: A local class, a local variable, or a friend function defined in a templated entity is a templated entity.  
— end note]

- <sup>9</sup> A *template-declaration* is written in terms of its template parameters. The optional *requires-clause* following a *template-parameter-list* allows the specification of constraints (??) on template arguments (??). The *requires-clause* introduces the *constraint-expression* that results from interpreting the *constraint-logical-or-expression* as a *constraint-expression*. The *constraint-logical-or-expression* of a *requires-clause* is an unevaluated operand (??). [Note: The expression in a *requires-clause* uses a restricted grammar to avoid ambiguities. Parentheses can be used to specify arbitrary expressions in a *requires-clause*. [Example:

```
template<int N> requires N == sizeof new unsigned short
int f(); // error: parentheses required around == expression
— end example] — end note]
```

- <sup>10</sup> A function template, member function of a class template, variable template, or static data member of a class template shall be defined in every translation unit in which it is implicitly instantiated (??) unless the corresponding specialization is explicitly instantiated (??) in some translation unit; no diagnostic is required.

## 17.1 Template parameters

[temp.param]

- <sup>1</sup> The syntax for *template-parameters* is:

```
template-parameter:
    type-parameter
    parameter-declaration
    constrained-parameter

type-parameter:
    type-parameter-key ...opt identifieropt
    type-parameter-key identifieropt = type-id
    template-head type-parameter-key ...opt identifieropt
    template-head type-parameter-key identifieropt = id-expression

type-parameter-key:
    class
    typename

constrained-parameter:
    qualified-concept-name ... identifieropt
    qualified-concept-name identifieropt default-template-argumentopt

qualified-concept-name:
    nested-name-specifieropt concept-name
    nested-name-specifieropt partial-concept-id

partial-concept-id:
    concept-name < template-argument-listopt >

default-template-argument:
    = type-id
    = id-expression
    = initializer-clause
```

[Note: The > token following the *template-parameter-list* of a *type-parameter* may be the product of replacing a >> token by two consecutive > tokens (??). — end note]

- <sup>2</sup> There is no semantic difference between **class** and **typename** in a *type-parameter-key*. **typename** followed by an *unqualified-id* names a template type parameter. **typename** followed by a *qualified-id* denotes the type in

a non-type<sup>136</sup> *parameter-declaration*. A *template-parameter* of the form `class identifier` is a *type-parameter*. [Example:

```
class T { /* ... */ };
int i;

template<class T, T i> void f(T t) {
    T t1 = i;           // template-parameters T and i
    ::T t2 = ::i;       // global namespace members T and i
}
```

Here, the template `f` has a *type-parameter* called `T`, rather than an unnamed non-type *template-parameter* of class `T`. —end example] A storage class shall not be specified in a *template-parameter* declaration. Types shall not be defined in a *template-parameter* declaration.

- <sup>3</sup> A *type-parameter* whose identifier does not follow an ellipsis defines its *identifier* to be a *typedef-name* (if declared without `template`) or *template-name* (if declared with `template`) in the scope of the template declaration. [Note: A template argument may be a class template or alias template. For example,

```
template<class T> class myarray { /* ... */ };

template<class K, class V, template<class T> class C = myarray>
class Map {
    C<K> key;
    C<V> value;
};

—end note]
```

- <sup>4</sup> A non-type *template-parameter* shall have one of the following (optionally cv-qualified) types:

- (4.1) — integral or enumeration type,
- (4.2) — pointer to object or pointer to function,
- (4.3) — lvalue reference to object or lvalue reference to function,
- (4.4) — pointer to member,
- (4.5) — `std::nullptr_t`, or
- (4.6) — a type that contains a placeholder type (??).

- <sup>5</sup> [Note: Other types are disallowed either explicitly below or implicitly by the rules governing the form of *template-arguments* (??). —end note] The top-level *cv-qualifiers* on the *template-parameter* are ignored when determining its type.

- <sup>6</sup> A non-type non-reference *template-parameter* is a prvalue. It shall not be assigned to or in any other way have its value changed. A non-type non-reference *template-parameter* cannot have its address taken. When a non-type non-reference *template-parameter* is used as an initializer for a reference, a temporary is always used. [Example:

```
template<const X& x, int i> void f() {
    i++;                  // error: change of template-parameter value
```

---

<sup>136</sup>) Since template *template-parameters* and template *template-arguments* are treated as types for descriptive purposes, the terms *non-type parameter* and *non-type argument* are used to refer to non-type, non-template parameters and arguments.

```

&x;                      // OK
&i;                      // error: address of non-reference template-parameter

int& ri = i;            // error: non-const reference bound to temporary
const int& cri = i;      // OK: const reference bound to temporary
}

— end example]

```

- 7 A non-type *template-parameter* shall not be declared to have floating-point, class, or void type. [ *Example*:

```

template<double d> class X;      // error
template<double* pd> class Y;    // OK
template<double& rd> class Z;    // OK

```

— end example]

- 8 A non-type *template-parameter* of type “array of T” or of function type T is adjusted to be of type “pointer to T”. [ *Example*:

```

template<int* a> struct R { /* ... */ };
template<int b[5]> struct S { /* ... */ };

int p;
R<&p> w;                  // OK
S<&p> x;                  // OK due to parameter adjustment
int v[5];
R<v> y;                  // OK due to implicit argument conversion
S<v> z;                  // OK due to both adjustment and conversion

```

— end example]

- 9 A *partial-concept-id* is a *concept-name* followed by a sequence of *template-arguments*. These template arguments are used to form a *constraint-expression* as described below.

- 10 A *constrained-parameter* declares a template parameter whose kind (type, non-type, template) and type match that of the prototype parameter (??) of the concept designated by the *qualified-concept-name* in the *constrained-parameter*. Let X be the prototype parameter of the designated concept. The declared template parameter is determined by the kind of X (type, non-type, template) and the optional ellipsis in the *constrained-parameter* as follows.

- (10.1) — If X is a type *template-parameter*, the declared parameter is a type *template-parameter*.
- (10.2) — If X is a non-type *template-parameter*, the declared parameter is a non-type *template-parameter* having the same type as X.
- (10.3) — If X is a template *template-parameter*, the declared parameter is a template *template-parameter* having the same *template-parameter-list* as X, excluding default template arguments.
- (10.4) — If the *qualified-concept-name* is followed by an ellipsis, then the declared parameter is a template parameter pack (??).

[ *Example*:

```

template<typename T> concept C1 = true;
template<template<typename> class X> concept C2 = true;
template<int N> concept C3 = true;
template<typename... Ts> concept C4 = true;
template<char... Cs> concept C5 = true;

```

```

template<C1 T> void f1();           // OK, T is a type template-parameter
template<C2 X> void f2();           // OK, X is a template with one type-parameter
template<C3 N> void f3();           // OK, N has type int
template<C4... Ts> void f4();       // OK, Ts is a template parameter pack of types
template<C4 T> void f5();           // OK, T is a type template-parameter
template<C5... Cs> void f6();       // OK, Cs is a template parameter pack of chars
— end example]

```

- <sup>11</sup> A *constrained-parameter* introduces a *constraint-expression* (??). The expression is derived from the *qualified-concept-name* Q in the *constrained-parameter*, its designated concept C, and the declared template parameter P.

- (11.1) — First, a template argument A is formed from P. If P declares a template parameter pack (??) and C is a variadic concept (??), then A is the pack expansion P.... Otherwise, A is the *id-expression* P.
- (11.2) — Then, an *id-expression* E is formed as follows. If Q is a *concept-name*, then E is C<A>. Otherwise, Q is a *partial-concept-id* of the form C<A<sub>1</sub>, A<sub>2</sub>, ..., A<sub>n</sub>>, and E is C<A, A<sub>1</sub>, A<sub>2</sub>, ..., A<sub>n</sub>>.
- (11.3) — Finally, if P declares a template parameter pack and C is not a variadic concept, E is adjusted to be the *fold-expression* (E && ...) (??).

E is the introduced *constraint-expression*. [Example:

```

template<typename T> concept C1 = true;
template<typename... Ts> concept C2 = true;
template<typename T, typename U> concept C3 = true;

template<C1 T> struct s1;           // associates C1<T>
template<C1... T> struct s2;         // associates (C1<T> && ...)
template<C2... T> struct s3;         // associates C2<T...>
template<C3<int> T> struct s4;       // associates C3<T, int>

```

— end example]

- <sup>12</sup> A *default template-argument* is a *template-argument* (??) specified after = in a *template-parameter*. A default *template-argument* may be specified for any kind of *template-parameter* (type, non-type, template) that is not a template parameter pack (??). A default *template-argument* may be specified in a template declaration. A default *template-argument* shall not be specified in the *template-parameter-lists* of the definition of a member of a class template that appears outside of the member's class. A default *template-argument* shall not be specified in a friend class template declaration. If a friend function template declaration specifies a default *template-argument*, that declaration shall be a definition and shall be the only declaration of the function template in the translation unit.

- <sup>13</sup> The default *template-argument* of a *constrained-parameter* shall match the kind (type, non-type, template) of the declared template parameter. [Example:

```

template<typename T> concept C1 = true;
template<int N> concept C2 = true;
template<template<typename> class X> concept C3 = true;

template<typename T> struct S0;

template<C1 T = int> struct S1; // OK
template<C2 N = 0> struct S2;  // OK

```

```
template<C3 X = S0> struct S3; // OK
template<C1 T = 0> struct S4; // error: default argument is not a type
— end example]
```

- <sup>14</sup> The set of default *template-arguments* available for use is obtained by merging the default arguments from all prior declarations of the template in the same way default function arguments are (??). [Example:

```
template<class T1, class T2 = int> class A;
template<class T1 = int, class T2> class A;
```

is equivalent to

```
template<class T1 = int, class T2 = int> class A;
— end example]
```

- <sup>15</sup> If a *template-parameter* of a class template, variable template, or alias template has a default *template-argument*, each subsequent *template-parameter* shall either have a default *template-argument* supplied or be a template parameter pack. If a *template-parameter* of a primary class template, primary variable template, or alias template is a template parameter pack, it shall be the last *template-parameter*. A template parameter pack of a function template shall not be followed by another template parameter unless that template parameter can be deduced from the parameter-type-list (??) of the function template or has a default argument (??). A template parameter of a deduction guide template (??) that does not have a default argument shall be deducible from the parameter-type-list of the deduction guide template. [Example:

```
template<class T1 = int, class T2> class B; // error
```

```
// U can be neither deduced from the parameter-type-list nor specified
template<class... T, class... U> void f() { } // error
template<class... T, class U> void g() { } // error
```

— end example]

- <sup>16</sup> A *template-parameter* shall not be given default arguments by two different declarations in the same scope. [Example:

```
template<class T = int> class X;
template<class T = int> class X { /* ... */ }; // error
— end example]
```

- <sup>17</sup> When parsing a default *template-argument* for a non-type *template-parameter*, the first non-nested > is taken as the end of the *template-parameter-list* rather than a greater-than operator. [Example:

```
template<int i = 3 > 4 > // syntax error
class X { /* ... */ };
```

```
template<int i = (3 > 4) > // OK
class Y { /* ... */ };
```

— end example]

- <sup>18</sup> A *template-parameter* of a template *template-parameter* is permitted to have a default *template-argument*. When such default arguments are specified, they apply to the template *template-parameter* in the scope of the template *template-parameter*. [Example:

```
template <class T = float> struct B {};
```

```

template <template <class TT = float> class T> struct A {
    inline void f();
    inline void g();
};

template <template <class TT> class T> void A<T>::f() {
    T<> t;           // error: TT has no default template argument
}

template <template <class TT = char> class T> void A<T>::g() {
    T<> t;           // OK, T<char>
}

— end example]

```

- <sup>19</sup> If a *template-parameter* is a *type-parameter* with an ellipsis prior to its optional *identifier* or is a *parameter-declaration* that declares a parameter pack (??), then the *template-parameter* is a template parameter pack (??). A template parameter pack that is a *parameter-declaration* whose type contains one or more unexpanded parameter packs is a pack expansion. Similarly, a template parameter pack that is a *type-parameter* with a *template-parameter-list* containing one or more unexpanded parameter packs is a pack expansion. A template parameter pack that is a pack expansion shall not expand a parameter pack declared in the same *template-parameter-list*. [Example:

```

template <class... Types>                                // Types is a template type parameter pack
    class Tuple;                                         // but not a pack expansion

template <class T, int... Dims>                          // Dims is a non-type template parameter pack
    struct multi_array;                                  // but not a pack expansion

template <class... T>
    struct value_holder {
        template <T... Values> struct apply { };          // Values is a non-type template parameter pack
    };                                                 // and a pack expansion

template <class... T, T... Values>                      // error: Values expands template type parameter
    struct static_array;                                // pack T within the same template parameter list

— end example]

```

## 17.2 Names of template specializations

[temp.names]

- <sup>1</sup> A template specialization (??) can be referred to by a *template-id*:

```

simple-template-id:
    template-name < template-argument-listopt >

template-id:
    simple-template-id
    operator-function-id < template-argument-listopt >
    literal-operator-id < template-argument-listopt >

template-name:
    identifier

template-argument-list:
    template-argument ...opt
    template-argument-list , template-argument ...opt

```

*template-argument:*

- constant-expression*
- type-id*
- id-expression*

[*Note*: The name lookup rules (??) are used to associate the use of a name with a template declaration; that is, to identify a name as a *template-name*. — *end note*]

- 2 For a *template-name* to be explicitly qualified by the template arguments, the name must be considered to refer to a template. [*Note*: Whether a name actually refers to a template cannot be known in some cases until after argument dependent lookup is done (??). — *end note*] A name is considered to refer to a template if name lookup finds a *template-name* or an overload set that contains a function template. A name is also considered to refer to a template if it is an *unqualified-id* followed by a < and name lookup finds either one or more functions or finds nothing.
- 3 When a name is considered to be a *template-name*, and it is followed by a <, the < is always taken as the delimiter of a *template-argument-list* and never as the less-than operator. When parsing a *template-argument-list*, the first non-nested ><sup>137</sup> is taken as the ending delimiter rather than a greater-than operator. Similarly, the first non-nested >> is treated as two consecutive but distinct > tokens, the first of which is taken as the end of the *template-argument-list* and completes the *template-id*. [*Note*: The second > token produced by this replacement rule may terminate an enclosing *template-id* construct or it may be part of a different construct (e.g., a cast). — *end note*] [*Example*:

```
template<int i> class X { /* ... */ };

X< 1>2 > x1;                                // syntax error
X<(1>2)> x2;                                // OK

template<class T> class Y { /* ... */ };
Y<X<1>> x3;                                // OK, same as Y<X<1> > x3;
Y<X<6>>1>> x4;                            // syntax error
Y<X<(6>>1)>> x5;                            // OK
```

— *end example*]

- 4 The keyword **template** is said to appear at the top level in a *qualified-id* if it appears outside of a *template-argument-list* or *decltype-specifier*. In a *qualified-id* of a *declarator-id* or in a *qualified-id* formed by a *class-head-name* (??) or *enum-head-name* (??), the keyword **template** shall not appear at the top level. In a *qualified-id* used as the name in a *typename-specifier* (??), *elaborated-type-specifier* (??), *using-declaration* (??), or *class-or-decltype* (??), an optional keyword **template** appearing at the top level is ignored. In these contexts, a < token is always assumed to introduce a *template-argument-list*. In all other contexts, when naming a template specialization of a member of an unknown specialization (??), the member template name shall be prefixed by the keyword **template**. [*Example*:

```
struct X {
    template<std::size_t> X* alloc();
    template<std::size_t> static X* adjust();
};

template<class T> void f(T* p) {
    T* p1 = p->alloc<200>();                // ill-formed: < means less than
```

(137) A > that encloses the *type-id* of a *dynamic\_cast*, *static\_cast*, *reinterpret\_cast* or *const\_cast*, or which encloses the *template-arguments* of a subsequent *template-id*, is considered nested for the purpose of this description.

```

T* p2 = p->template alloc<200>();           // OK: < starts template argument list
T::adjust<100>();                            // ill-formed: < means less than
T::template adjust<100>();                   // OK: < starts template argument list
}

— end example]

```

- 5 A name prefixed by the keyword `template` shall be a *template-id* or the name shall refer to a class template or an alias template. [Note: The keyword `template` may not be applied to non-template members of class templates. — end note] [Note: As is the case with the `typename` prefix, the `template` prefix is allowed in cases where it is not strictly necessary; i.e., when the *nested-name-specifier* or the expression on the left of the `->` or `.` is not dependent on a *template-parameter*, or the use does not appear in the scope of a template. — end note] [Example:

```

template <class T> struct A {
    void f(int);
    template <class U> void f(U);
};

template <class T> void f(T t) {
    A<T> a;
    a.template f<>(t);                      // OK: calls template
    a.template f(t);                         // error: not a template-id
}

template <class T> struct B {
    template <class T2> struct C { };
};

// OK: T::template C names a class template:
template <class T, template <class X> class TT = T::template C> struct D { };
D<B<int> > db;

— end example]

```

- 6 A *simple-template-id* that names a class template specialization is a *class-name* (??).

- 7 A *template-id* that names an alias template specialization is a *type-name*.

- 8 When the *template-name* of a *simple-template-id* names a constrained non-function template or a constrained template *template-parameter*, but not a member template that is a member of an unknown specialization (??), and all *template-arguments* in the *simple-template-id* are non-dependent (??), the associated constraints (??) of the constrained template shall be satisfied (??). [Example:

```

template<typename T> concept C1 = sizeof(T) != sizeof(int);

template<C1 T> struct S1 { };
template<C1 T> using Ptr = T*;

S1<int>* p;                                // error: constraints not satisfied
Ptr<int> p;                                // error: constraints not satisfied

template<typename T>
struct S2 { Ptr<int> x; };                  // error, no diagnostic required

```

```

template<typename T>
struct S3 { Ptr<T> x; } ; // OK, satisfaction is not required

S3<int> x; // error: constraints not satisfied

template<template<C1 T> class X>
struct S4 {
    X<int> x; // error, no diagnostic required
};

template<typename T> concept C2 = sizeof(T) == 1;

template<C2 T> struct S { };

template struct S<char[2]>; // error: constraints not satisfied
template<> struct S<char[2]> { }; // error: constraints not satisfied
— end example]

```

### 17.3 Template arguments

[temp.arg]

- <sup>1</sup> There are three forms of *template-argument*, corresponding to the three forms of *template-parameter*: type, non-type and template. The type and form of each *template-argument* specified in a *template-id* shall match the type and form specified for the corresponding parameter declared by the template in its *template-parameter-list*. When the parameter declared by the template is a template parameter pack (??), it will correspond to zero or more *template-arguments*. [Example:

```

template<class T> class Array {
    T* v;
    int sz;
public:
    explicit Array(int);
    T& operator[](int);
    T& elem(int i) { return v[i]; }
};

Array<int> v1(20);
typedef std::complex<double> dcomplex; // std::complex is a standard library template
Array<dcomplex> v2(30);
Array<dcomplex> v3(40);

void bar() {
    v1[3] = 7;
    v2[3] = v3.elem(4) = dcomplex(7,8);
}
— end example]

```

- <sup>2</sup> In a *template-argument*, an ambiguity between a *type-id* and an expression is resolved to a *type-id*, regardless of the form of the corresponding *template-parameter*.<sup>138</sup> [Example:

<sup>138</sup>) There is no such ambiguity in a default *template-argument* because the form of the *template-parameter* determines the allowable forms of the *template-argument*.

```

template<class T> void f();
template<int I> void f();

void g() {
    f<int()>();           // int() is a type-id: call the first f()
}

— end example]

```

- 3 The name of a *template-argument* shall be accessible at the point where it is used as a *template-argument*. [Note: If the name of the *template-argument* is accessible at the point where it is used as a *template-argument*, there is no further access restriction in the resulting instantiation where the corresponding *template-parameter* name is used. — end note] [Example:

```

template<class T> class X {
    static T t;
};

class Y {
private:
    struct S { /* ... */ };
    X<S> x;           // OK: S is accessible
    // X<Y::S> has a static member of type Y::S
    // OK: even though Y::S is private
};

X<Y::S> y;           // error: S not accessible

```

— end example] For a *template-argument* that is a class type or a class template, the template definition has no special access rights to the members of the *template-argument*. [Example:

```

template <template <class TT> class T> class A {
    typename T<int>::S s;
};

template <class U> class B {
private:
    struct S { /* ... */ };
};

A<B> b;           // ill-formed: A has no access to B::S

```

- end example]
- 4 When template argument packs or default *template-arguments* are used, a *template-argument* list can be empty. In that case the empty <> brackets shall still be used as the *template-argument-list*. [Example:

```

template<class T = char> class String;
String<>* p;           // OK: String<char>
String* q;             // syntax error
template<class ... Elements> class Tuple;
Tuple<>* t;           // OK: Elements is empty
Tuple* u;             // syntax error

```

— end example]

- <sup>5</sup> An explicit destructor call (??) for an object that has a type that is a class template specialization may explicitly specify the *template-arguments*. [ *Example*:

```
template<class T> struct A {
    ~A();
};

void f(A<int>* p, A<int>* q) {
    p->A<int>::~A();           // OK: destructor call
    q->A<int>::~A<int>();     // OK: destructor call
}

— end example ]
```

- <sup>6</sup> If the use of a *template-argument* gives rise to an ill-formed construct in the instantiation of a template specialization, the program is ill-formed.
- <sup>7</sup> When name lookup for the name in a *template-id* finds an overload set, both non-template functions in the overload set and function templates in the overload set for which the *template-arguments* do not match the *template-parameters* are ignored. If none of the function templates have matching *template-parameters*, the program is ill-formed.
- <sup>8</sup> When a *simple-template-id* does not name a function, a default *template-argument* is implicitly instantiated (??) when the value of that default argument is needed. [ *Example*:

```
template<typename T, typename U = int> struct S { };
S<bool>* p;           // the type of p is S<bool, int>*
```

The default argument for U is instantiated to form the type S<bool, int>\*. — end example ]

- <sup>9</sup> A *template-argument* followed by an ellipsis is a pack expansion (??).

### 17.3.1 Template type arguments

[temp.arg.type]

- <sup>1</sup> A *template-argument* for a *template-parameter* which is a type shall be a *type-id*.

- <sup>2</sup> [ *Example*:

```
template <class T> class X { };
template <class T> void f(T t) { }
struct { } unnamed_obj;

void f() {
    struct A { };
    enum { e1 };
    typedef struct { } B;
    B b;
    X<A> x1;           // OK
    X<A*> x2;           // OK
    X<B> x3;           // OK
    f(e1);             // OK
    f(unnamed_obj);     // OK
    f(b);               // OK
}
```

— end example ] [ *Note*: A template type argument may be an incomplete type (??). — end note ]

### 17.3.2 Template non-type arguments

[temp.arg.nontype]

- <sup>1</sup> If the type of a *template-parameter* contains a placeholder type (??, ??), the deduced parameter type is determined from the type of the *template-argument* by placeholder type deduction (??). If a deduced parameter type is not permitted for a *template-parameter* declaration (??), the program is ill-formed.
- <sup>2</sup> A *template-argument* for a non-type *template-parameter* shall be a converted constant expression (??) of the type of the *template-parameter*. For a non-type *template-parameter* of reference or pointer type, the value of the constant expression shall not refer to (or for a pointer type, shall not be the address of):

- (2.1) — a subobject (??),
- (2.2) — a temporary object (??),
- (2.3) — a string literal (??),
- (2.4) — the result of a `typeid` expression (??), or
- (2.5) — a predefined `__func__` variable (??).

[*Note*: If the *template-argument* represents a set of overloaded functions (or a pointer or member pointer to such), the matching function is selected from the set (??). — *end note*]

- <sup>3</sup> [*Example*:

```

template<const int* pci> struct X { /* ... */ };
int ai[10];
X<ai> xi;                                // array to pointer and qualification conversions

struct Y { /* ... */ };
template<const Y& b> struct Z { /* ... */ };
Y y;
Z<y> z;                                    // no conversion, but note extra cv-qualification

template<int (&pa)[5]> struct W { /* ... */ };
int b[5];
W<b> w;                                    // no conversion

void f(char);
void f(int);

template<void (*pf)(int)> struct A { /* ... */ };

A<&f> a;                                // selects f(int)

template<auto n> struct B { /* ... */ };
B<5> b1;                                  // OK: template parameter type is int
B<'a'> b2;                                // OK: template parameter type is char
B<2.5> b3;                                // error: template parameter type cannot be double

```

— *end example*]

- <sup>4</sup> [*Note*: A string literal (??) is not an acceptable *template-argument*. [*Example*:

```

template<class T, const char* p> class X {
    /* ... */
};

```

```
X<int, "Studebaker"> x1;           // error: string literal as template-argument

const char p[] = "Vivisectionist";
X<int,p> x2;                      // OK

— end example] — end note]
```

- 5 [ Note: The address of an array element or non-static data member is not an acceptable *template-argument*.  
 [ Example:

```
template<int* p> class X { };

int a[10];
struct S { int m; static int s; } s;

X<&a[2]> x3;                     // error: address of array element
X<&s.m> x4;                      // error: address of non-static member
X<&s.s> x5;                      // OK: address of static member
X<&S::s> x6;                      // OK: address of static member

— end example] — end note]
```

- 6 [ Note: A temporary object is not an acceptable *template-argument* when the corresponding *template-parameter* has reference type.  
 [ Example:

```
template<const int& CRI> struct B { /* ... */ };

B<1> b2;                         // error: temporary would be required for template argument

int c = 1;
B<c> b1;                         // OK

— end example] — end note]
```

### 17.3.3 Template template arguments

[temp.arg.template]

- 1 A *template-argument* for a template *template-parameter* shall be the name of a class template or an alias template, expressed as *id-expression*. When the *template-argument* names a class template, only primary class templates are considered when matching the template template argument with the corresponding parameter; partial specializations are not considered even if their parameter lists match that of the template template parameter.
- 2 Any partial specializations (??) associated with the primary class template or primary variable template are considered when a specialization based on the template *template-parameter* is instantiated. If a specialization is not visible at the point of instantiation, and it would have been selected had it been visible, the program is ill-formed, no diagnostic required. [ Example:

```
template<class T> class A {      // primary template
    int x;
};

template<class T> class A<T*> { // partial specialization
    long x;
};

template<template<class U> class V> class C {
    V<int> y;
```

```

    V<int*> z;
};

C<A> c;           // V<int> within C<A> uses the primary template, so c.y.x has type int
                  // V<int*> within C<A> uses the partial specialization, so c.z.x has type long
— end example]

```

- 3 A *template-argument* matches a template *template-parameter* P when P is at least as specialized as the *template-argument* A. If P contains a parameter pack, then A also matches P if each of A's template parameters matches the corresponding template parameter in the *template-head* of P. Two template parameters match if they are of the same kind (type, non-type, template), for non-type *template-parameters*, their types are equivalent (??), and for template *template-parameters*, each of their corresponding *template-parameters* matches, recursively. When P's *template-head* contains a template parameter pack (??), the template parameter pack will match zero or more template parameters or template parameter packs in the *template-head* of A with the same type and form as the template parameter pack in P (ignoring whether those template parameters are template parameter packs).

[*Example*:

```

template<class T> class A { /* ... */ };
template<class T, class U = T> class B { /* ... */ };
template<class ... Types> class C { /* ... */ };
template<auto n> class D { /* ... */ };
template<template<class> class P> class X { /* ... */ };
template<template<class ...> class Q> class Y { /* ... */ };
template<template<int> class R> class Z { /* ... */ };

X<A> xa;          // OK
X<B> xb;          // OK
X<C> xc;          // OK
Y<A> ya;          // OK
Y<B> yb;          // OK
Y<C> yc;          // OK
Z<D> zd;          // OK

```

— end example] [*Example*:

```

template <class T> struct eval;

template <template <class, class...> class TT, class T1, class... Rest>
struct eval<TT<T1, Rest...>> { };

template <class T1> struct A;
template <class T1, class T2> struct B;
template <int N> struct C;
template <class T1, int N> struct D;
template <class T1, class T2, int N = 17> struct E;

eval<A<int>> eA;          // OK: matches partial specialization of eval
eval<B<int, float>> eB;    // OK: matches partial specialization of eval
eval<C<17>> eC;          // error: C does not match TT in partial specialization
eval<D<int, 17>> eD;      // error: D does not match TT in partial specialization
eval<E<int, float>> eE;    // error: E does not match TT in partial specialization

```

— end example] [Example:

```
template<typename T> concept C = requires (T t) { t.f(); };
template<typename T> concept D = C<T> && requires (T t) { t.g(); };

template<template<C> class P> struct S { };

template<C> struct X { };
template<D> struct Y { };
template<typename T> struct Z { };

S<X> s1;           // OK, X and P have equivalent constraints
S<Y> s2;           // error: P is not at least as specialized as Y
S<Z> s3;           // OK, P is at least as specialized as Z
```

— end example]

- <sup>4</sup> A template *template-parameter* P is at least as specialized as a template *template-argument* A if, given the following rewrite to two function templates, the function template corresponding to P is at least as specialized as the function template corresponding to A according to the partial ordering rules for function templates (??). Given an invented class template X with the *template-head* of A (including default arguments and *requires-clause*, if any):

- (4.1) — Each of the two function templates has the same template parameters and *requires-clause* (if any), respectively, as P or A.
- (4.2) — Each function template has a single function parameter whose type is a specialization of X with template arguments corresponding to the template parameters from the respective function template where, for each template parameter PP in the *template-head* of the function template, a corresponding template argument AA is formed. If PP declares a parameter pack, then AA is the pack expansion PP... (??); otherwise, AA is the *id-expression* PP.

If the rewrite produces an invalid type, then P is not at least as specialized as A.

## 17.4 Template constraints

[temp.constr]

- <sup>1</sup> [Note: This subclause defines the meaning of constraints on template arguments. The abstract syntax and satisfaction rules are defined in ???. Constraints are associated with declarations in ???. Declarations are partially ordered by their associated constraints (??). — end note]

### 17.4.1 Constraints

[temp.constr.constr]

- <sup>1</sup> A *constraint* is a sequence of logical operations and operands that specifies requirements on template arguments. The operands of a logical operation are constraints. There are three different kinds of constraints:

- (1.1) — conjunctions (??),
- (1.2) — disjunctions (??), and
- (1.3) — atomic constraints (??)

- <sup>2</sup> In order for a constrained template to be instantiated (??), its associated constraints (??) shall be satisfied as described in the following subsections. [Note: Forming the name of a specialization of a class template, a variable template, or an alias template (??) requires the satisfaction of its constraints. Overload resolution (??) requires the satisfaction of constraints on functions and function templates. — end note]

### 17.4.1.1 Logical operations

[temp.constr.op]

- 1 There are two binary logical operations on constraints: conjunction and disjunction. [ *Note:* These logical operations have no corresponding C++ syntax. For the purpose of exposition, conjunction is spelled using the symbol  $\wedge$  and disjunction is spelled using the symbol  $\vee$ . The operands of these operations are called the left and right operands. In the constraint  $A \wedge B$ ,  $A$  is the left operand, and  $B$  is the right operand. — *end note* ]
- 2 A *conjunction* is a constraint taking two operands. To determine if a conjunction is *satisfied*, the satisfaction of the first operand is checked. If that is not satisfied, the conjunction is not satisfied. Otherwise, the conjunction is satisfied if and only if the second operand is satisfied.
- 3 A *disjunction* is a constraint taking two operands. To determine if a disjunction is *satisfied*, the satisfaction of the first operand is checked. If that is satisfied, the disjunction is satisfied. Otherwise, the disjunction is satisfied if and only if the second operand is satisfied.

4 [ *Example:*

```
template<typename T>
constexpr bool get_value() { return T::value; }

template<typename T>
requires (sizeof(T) > 1) && get_value<T>()
void f(T);           // has associated constraint sizeof(T) > 1 & get_value<T>()

void f(int);

f('a'); // OK: calls f(int)
```

In the satisfaction of the associated constraints (??) of `f`, the constraint `sizeof(char) > 1` is not satisfied; the second operand is not checked for satisfaction. — *end example* ]

### 17.4.1.2 Atomic constraints

[temp.constr.atomic]

- 1 An *atomic constraint* is formed from an expression  $E$  and a mapping from the template parameters that appear within  $E$  to template arguments involving the template parameters of the constrained entity, called the *parameter mapping* (??). [ *Note:* Atomic constraints are formed by constraint normalization (??).  $E$  is never a logical AND expression (??) nor a logical OR expression (??). — *end note* ]
  - 2 Two atomic constraints are *identical* if they are formed from the same *expression* and the targets of the parameter mappings are equivalent according to the rules for expressions described in ??.
  - 3 To determine if an atomic constraint is *satisfied*, the parameter mapping and template arguments are first substituted into its expression. If substitution results in an invalid type or expression, the constraint is not satisfied. Otherwise, the lvalue-to-rvalue conversion (??) is performed if necessary, and  $E$  shall be a constant expression of type `bool`. The constraint is satisfied if and only if evaluation of  $E$  results in `true`.
- [ *Example:*

```
template<typename T> concept C =
    sizeof(T) == 4 && !true;      // requires atomic constraints sizeof(T) == 4 and !true

template<typename T> struct S {
    constexpr operator bool() const { return true; }
};
```

```

template<typename T> requires (S<T>{})
void f(T);           // #1
void f(int);         // #2

void g() {
    f(0);           // error: expression S<int>{} does not have type bool
}
// while checking satisfaction of deduced arguments of #1;
// call is ill-formed even though #2 is a better match

— end example]

```

### 17.4.2 Constrained declarations

[temp.constr.decl]

- <sup>1</sup> A template declaration (??) or function declaration (??) can be constrained by the use of a *requires-clause*. This allows the specification of constraints for that declaration as an expression:

*constraint-expression:*

*logical-or-expression*

- 2 Constraints can also be associated with a declaration through the use of *constrained-parameters* in a *template-parameter-list*. Each of these forms introduces additional *constraint-expressions* that are used to constrain the declaration.
- 3 A template's *associated constraints* are defined as follows:
  - (3.1) — If there are no introduced *constraint-expressions*, the declaration has no associated constraints.
  - (3.2) — Otherwise, if there is a single introduced *constraint-expression*, the associated constraints are the normal form (??) of that expression.
  - (3.3) — Otherwise, the associated constraints are the normal form of a logical AND expression (??) whose operands are in the following order:
    - (3.3.1) — the *constraint-expression* introduced by each *constrained-parameter* (??) in the declaration's *template-parameter-list*, in order of appearance, and
    - (3.3.2) — the *constraint-expression* introduced by a *requires-clause* following a *template-parameter-list* (??), and
    - (3.3.3) — the *constraint-expression* introduced by a trailing *requires-clause* (??) of a function declaration (??).

The formation of the associated constraints establishes the order in which constraints are instantiated when checking for satisfaction (??). [Example:

```

template<typename T> concept C = true;

template<C T> void f1(T);
template<typename T> requires C<T> void f2(T);
template<typename T> void f3(T) requires C<T>;

```

The functions *f1*, *f2*, and *f3* have the associated constraint *C<T>*.

```

template<typename T> concept C1 = true;
template<typename T> concept C2 = sizeof(T) > 0;

template<C1 T> void f4(T) requires C2<T>;
template<typename T> requires C1<T> && C2<T> void f5(T);

```

The associated constraints of *f4* and *f5* are *C1<T> & C2<T>*.

```
template<C1 T> requires C2<T> void f6();
template<C2 T> requires C1<T> void f7();
```

The associated constraints of `f6` are `C1<T>  $\wedge$  C2<T>`, and those of `f7` are `C2<T>  $\wedge$  C1<T>`. — end example]

### 17.4.3 Constraint normalization

[temp.constr.normal]

- <sup>1</sup> The *normal form* of an *expression E* is a constraint (??) that is defined as follows:

- (1.1) — The normal form of an expression ( `E` ) is the normal form of `E`.
- (1.2) — The normal form of an expression `E1 || E2` is the disjunction (??) of the normal forms of `E1` and `E2`.
- (1.3) — The normal form of an expression `E1 && E2` is the conjunction of the normal forms of `E1` and `E2`.
- (1.4) — The normal form of an *id-expression* of the form `C<A1, A2, ..., An>`, where `C` names a concept, is the normal form of the *constraint-expression* of `C`, after substituting `A1, A2, ..., An` for `C`'s respective template parameters in the parameter mappings in each atomic constraint. If any such substitution results in an invalid type or expression, the program is ill-formed; no diagnostic is required.

[ Example:

```
template<typename T> concept A = T::value || true;
template<typename U> concept B = A<U*>;
template<typename V> concept C = B<V&>;
```

Normalization of `B`'s *constraint-expression* is valid and results in `T::value` (with the mapping  $T \mapsto U^*$ )  $\vee$  `true` (with an empty mapping), despite the expression `T::value` being ill-formed for a pointer type `T`. Normalization of `C`'s *constraint-expression* results in the program being ill-formed, because it would form the invalid type `T&*` in the parameter mapping. — end example]

- (1.5) — The normal form of any other expression `E` is the atomic constraint whose expression is `E` and whose parameter mapping is the identity mapping.
- 2 The process of obtaining the normal form of a *constraint-expression* is called *normalization*. [ Note: Normalization of *constraint-expressions* is performed when determining the associated constraints (??) of a declaration and when evaluating the value of an *id-expression* that names a concept specialization (??). — end note ]

- <sup>3</sup> [ Example:

```
template<typename T> concept C1 = sizeof(T) == 1;
template<typename T> concept C2 = C1<T>() && 1 == 2;
template<typename T> concept C3 = requires { typename T::type; };
template<typename T> concept C4 = requires (T x) { ++x; }

template<C2 U> void f1(U);      // #1
template<C3 U> void f2(U);      // #2
template<C4 U> void f3(U);      // #3
```

The associated constraints of #1 are `sizeof(T) == 1` (with mapping  $T \mapsto U$ )  $\wedge$  `1 == 2`.

The associated constraints of #2 are `requires { typename T::type; }` (with mapping  $T \mapsto U$ ).

The associated constraints of #3 are `requires (T x) { ++x; }` (with mapping  $T \mapsto U$ ). — end example]

#### 17.4.4 Partial ordering by constraints

[temp.constr.order]

- 1 A constraint  $P$  *subsumes* a constraint  $Q$  if and only if, for every disjunctive clause  $P_i$  in the disjunctive normal form<sup>139</sup> of  $P$ ,  $P_i$  subsumes every conjunctive clause  $Q_j$  in the conjunctive normal form<sup>140</sup> of  $Q$ , where
  - (1.1) — a disjunctive clause  $P_i$  subsumes a conjunctive clause  $Q_j$  if and only if there exists an atomic constraint  $P_{ia}$  in  $P_i$  for which there exists an atomic constraint  $Q_{jb}$  in  $Q_j$  such that  $P_{ia}$  subsumes  $Q_{jb}$ , and
  - (1.2) — an atomic constraint  $A$  subsumes another atomic constraint  $B$  if and only if the  $A$  and  $B$  are identical using the rules described in ??.

[Example: Let  $A$  and  $B$  be atomic constraints (??). The constraint  $A \wedge B$  subsumes  $A$ , but  $A$  does not subsume  $A \wedge B$ . The constraint  $A$  subsumes  $A \vee B$ , but  $A \vee B$  does not subsume  $A$ . Also note that every constraint subsumes itself. — end example]

- 2 [Note: The subsumption relation defines a partial ordering on constraints. This partial ordering is used to determine

- (2.1) — the best viable candidate of non-template functions (??),
- (2.2) — the address of a non-template function (??),
- (2.3) — the matching of template template arguments (??),
- (2.4) — the partial ordering of class template specializations (??), and
- (2.5) — the partial ordering of function templates (??).

— end note]

- 3 A declaration D1 is *at least as constrained* as a declaration D2 if

- (3.1) — D1 and D2 are both constrained declarations and D1's associated constraints subsume those of D2; or
- (3.2) — D2 has no associated constraints.

- 4 A declaration D1 is *more constrained* than another declaration D2 when D1 is at least as constrained as D2, and D2 is not at least as constrained as D1. [Example:

```
template<typename T> concept C1 = requires(T t) { --t; };
template<typename T> concept C2 = C1<T> && requires(T t) { *t; };

template<C1 T> void f(T);           // #1
template<C2 T> void f(T);           // #2
template<typename T> void g(T); // #3
template<C1 T> void g(T);           // #4

f(0);                           // selects #1
f((int*)0);                     // selects #2
g(true);                        // selects #3 because C1<bool> is not satisfied
g(0);                           // selects #4
```

— end example]

139) A constraint is in disjunctive normal form when it is a disjunction of clauses where each clause is a conjunction of atomic constraints. [Example: For atomic constraints  $A$ ,  $B$ , and  $C$ , the disjunctive normal form of the constraint  $A \wedge (B \vee C)$  is  $(A \wedge B) \vee (A \wedge C)$ . Its disjunctive clauses are  $(A \wedge B)$  and  $(A \wedge C)$ . — end example]

140) A constraint is in conjunctive normal form when it is a conjunction of clauses where each clause is a disjunction of atomic constraints. [Example: For atomic constraints  $A$ ,  $B$ , and  $C$ , the constraint  $A \wedge (B \vee C)$  is in conjunctive normal form. Its conjunctive clauses are  $A$  and  $(B \vee C)$ . — end example]

## 17.5 Type equivalence

[**temp.type**]

- <sup>1</sup> Two *template-ids* refer to the same class, function, or variable if
  - (1.1) — their *template-names*, *operator-function-ids*, or *literal-operator-ids* refer to the same template and
  - (1.2) — their corresponding type *template-arguments* are the same type and
  - (1.3) — their corresponding non-type template arguments of integral or enumeration type have identical values and
  - (1.4) — their corresponding non-type *template-arguments* of pointer type refer to the same object or function or are both the null pointer value and
  - (1.5) — their corresponding non-type *template-arguments* of pointer-to-member type refer to the same class member or are both the null member pointer value and
  - (1.6) — their corresponding non-type *template-arguments* of reference type refer to the same object or function and
  - (1.7) — their corresponding template *template-arguments* refer to the same template.

[*Example*:

```
template<class E, int size> class buffer { /* ... */ };
buffer<char,2*512> x;
buffer<char,1024> y;
```

declares x and y to be of the same type, and

```
template<class T, void(*err_fct)()> class list { /* ... */ };
list<int,&error_handler1> x1;
list<int,&error_handler2> x2;
list<int,&error_handler2> x3;
list<char,&error_handler2> x4;
```

declares x2 and x3 to be of the same type. Their type differs from the types of x1 and x4.

```
template<class T> struct X { };
template<class> struct Y { };
template<class T> using Z = Y<T>;
X<Y<int> > y;
X<Z<int> > z;
```

declares y and z to be of the same type. — *end example*]

- <sup>2</sup> If an expression e is type-dependent (??), `decltype(e)` denotes a unique dependent type. Two such *decltype-specifiers* refer to the same type only if their *expressions* are equivalent (??). [Note: However, such a type may be aliased, e.g., by a *typedef-name*. — *end note*]

## 17.6 Template declarations

[**temp.decls**]

- <sup>1</sup> A *template-id*, that is, the *template-name* followed by a *template-argument-list* shall not be specified in the declaration of a primary template declaration. [*Example*:

```
template<class T1, class T2, int I> class A<T1, T2, I> { }; // error
template<class T1, int I> void sort<T1, I>(T1 data[I]); // error
```

— *end example*] [Note: However, this syntax is allowed in class template partial specializations (??). — *end note*]

- <sup>2</sup> For purposes of name lookup and instantiation, default arguments, *partial-concept-ids*, *requires-clauses* (??), and *noexcept-specifiers* of function templates and of member functions of class templates are considered definitions; each default argument, *partial-concept-ids*, *requires-clause*, or *noexcept-specifier* is a separate definition which is unrelated to the templated function definition or to any other default arguments *partial-concept-ids*, *requires-clauses*, or *noexcept-specifiers*. For the purpose of instantiation, the substatements of a `constexpr` if statement (??) are considered definitions.
- <sup>3</sup> Because an *alias-declaration* cannot declare a *template-id*, it is not possible to partially or explicitly specialize an alias template.

### 17.6.1 Class templates

[temp.class]

- <sup>1</sup> A *class template* defines the layout and operations for an unbounded set of related types.
- <sup>2</sup> [Example: A single class template `List` might provide an unbounded set of class definitions: one class `List<T>` for every type `T`, each describing a linked list of elements of type `T`. Similarly, a class template `Array` describing a contiguous, dynamic array might be defined like this:

```
template<class T> class Array {
    T* v;
    int sz;
public:
    explicit Array(int);
    T& operator[](int);
    T& elem(int i) { return v[i]; }
};
```

The prefix `template<class T>` specifies that a template is being declared and that a *type-name* `T` may be used in the declaration. In other words, `Array` is a parameterized type with `T` as its parameter. —end example]

- <sup>3</sup> When a member function, a member class, a member enumeration, a static data member or a member template of a class template is defined outside of the class template definition, the member definition is defined as a template definition in which the *template-head* is equivalent to that of the class template (??). The names of the template parameters used in the definition of the member may be different from the template parameter names used in the class template definition. The template argument list following the class template name in the member definition shall name the parameters in the same order as the one used in the template parameter list of the member. Each template parameter pack shall be expanded with an ellipsis in the template argument list. [Example:

```
template<class T1, class T2> struct A {
    void f1();
    void f2();
};

template<class T2, class T1> void A<T2,T1>::f1() { }      // OK
template<class T2, class T1> void A<T1,T2>::f2() { }      // error

template<class ... Types> struct B {
    void f3();
    void f4();
};
```

```

template<class ... Types> void B<Types ...>::f3() { } // OK
template<class ... Types> void B<Types>::f4() { } // error

template<typename T> concept C = true;
template<typename T> concept D = true;

template<C T> struct S {
    void f();
    void g();
    void h();
    template<D U> struct Inner;
};

template<C A> void S<A>::f() { } // OK: template-heads match
template<typename T> void S<T>::g() { } // error: no matching declaration for S<T>

template<typename T> requires C<T> void S<T>::h() { } // error (no diagnostic required): template-heads are
// functionally equivalent but not equivalent

template<C X> template<D Y> struct S<X>::Inner { }; // OK
— end example]

```

- <sup>4</sup> In a redeclaration, partial specialization, explicit specialization or explicit instantiation of a class template, the *class-key* shall agree in kind with the original class template declaration (??).

### 17.6.1.1 Member functions of class templates

[temp.mem.func]

- <sup>1</sup> A member function of a class template may be defined outside of the class template definition in which it is declared. [Example:

```

template<class T> class Array {
    T* v;
    int sz;
public:
    explicit Array(int);
    T& operator[](int);
    T& elem(int i) { return v[i]; }
};

```

declares three function templates. The subscript function might be defined like this:

```

template<class T> T& Array<T>::operator[](int i) {
    if (i<0 || sz<=i) error("Array: range error");
    return v[i];
}

```

A constrained member function can be defined out of line:

```

template<typename T> concept C = requires {
    typename T::type;
};

template<typename T> struct S {
    void f() requires C<T>;
}

```

```

void g() requires C<T>;
};

template<typename T>
void S<T>::f() requires C<T> { }           // OK
template<typename T>
void S<T>::g() { }                         // error: no matching function in S<T>
— end example]

```

- <sup>2</sup> The *template-arguments* for a member function of a class template are determined by the *template-arguments* of the type of the object for which the member function is called. [Example: The *template-argument* for `Array<T>::operator[]()` will be determined by the `Array` to which the subscripting operation is applied.

```

Array<int> v1(20);
Array<dcomplex> v2(30);

v1[3] = 7;                                // Array<int>::operator[]()
v2[3] = dcomplex(7,8);                     // Array<dcomplex>::operator[]()
— end example]

```

### 17.6.1.2 Member classes of class templates

[temp.mem.class]

- <sup>1</sup> A member class of a class template may be defined outside the class template definition in which it is declared. [Note: The member class must be defined before its first use that requires an instantiation (??). For example,

```

template<class T> struct A {
    class B;
};

A<int>::B* b1;                           // OK: requires A to be defined but not A::B
template<class T> class A<T>::B { };
A<int>::B b2;                           // OK: requires A::B to be defined
— end note]

```

### 17.6.1.3 Static data members of class templates

[temp.static]

- <sup>1</sup> A definition for a static data member or static data member template may be provided in a namespace scope enclosing the definition of the static member's class template. [Example:

```

template<class T> class X {
    static T s;
};

template<class T> T X<T>::s = 0;

struct limits {
    template<class T>
        static const T min;           // declaration
};

template<class T>
const T limits::min = { };                // definition
— end example]

```

- <sup>2</sup> An explicit specialization of a static data member declared as an array of unknown bound can have a different bound from its definition, if any. [Example:

```
template <class T> struct A {
    static int i[];
};

template <class T> int A<T>::i[4];      // 4 elements
template <> int A<int>::i[] = { 1 };     // OK: 1 element

— end example]
```

#### 17.6.1.4 Enumeration members of class templates

[temp.mem.enum]

- <sup>1</sup> An enumeration member of a class template may be defined outside the class template definition. [Example:

```
template<class T> struct A {
    enum E : T;
};

A<int> a;
template<class T> enum A<T>::E : T { e1, e2 };
A<int>::E e = A<int>::e1;

— end example]
```

#### 17.6.2 Member templates

[temp.mem]

- <sup>1</sup> A template can be declared within a class or class template; such a template is called a member template. A member template can be defined within or outside its class definition or class template definition. A member template of a class template that is defined outside of its class template definition shall be specified with a *template-head* equivalent to that of the class template followed by a *template-head* equivalent to that of the member template (??). [Example:

```
template<class T> struct string {
    template<class T2> int compare(const T2&);

    template<class T2> string(const string<T2>& s) { /* ... */ }

};

template<class T> template<class T2> int string<T>::compare(const T2& s) {
}

— end example] [Example:

template<typename T> concept C1 = true;
template<typename T> concept C2 = sizeof(T) <= 4;

template<C1 T> struct S {
    template<C2 U> void f(U);
    template<C2 U> void g(U);
};

template<C1 T> template<C2 U>
void S<T>::f(U) { }           // OK
template<C1 T> template<typename U>
void S<T>::g(U) { }          // error: no matching function in S<T>
```

— end example]

- 2 A local class of non-closure type shall not have member templates. Access control rules (??) apply to member template names. A destructor shall not be a member template. A non-template member function (??) with a given name and type and a member function template of the same name, which could be used to generate a specialization of the same type, can both be declared in a class. When both exist, a use of that name and type refers to the non-template member unless an explicit template argument list is supplied. [Example:

```
template <class T> struct A {
    void f(int);
    template <class T2> void f(T2);
};

template <> void A<int>::f(int) {}                                // non-template member function
template <> template <> void A<int>::f<>(int) {} // member function template specialization

int main() {
    A<char> ac;
    ac.f(1);                                         // non-template
    ac.f('c');                                       // template
    ac.f<>(1);                                      // template
}

— end example]
```

- 3 A member function template shall not be virtual. [Example:

```
template <class T> struct AA {
    template <class C> virtual void g(C);           // error
    virtual void f();                               // OK
};
```

— end example]

- 4 A specialization of a member function template does not override a virtual function from a base class. [Example:

```
class B {
    virtual void f(int);
};

class D : public B {
    template <class T> void f(T); // does not override B::f(int)
    void f(int i) { f<>(i); } // overriding function that calls the template instantiation
};
```

— end example]

- 5 A specialization of a conversion function template is referenced in the same way as a non-template conversion function that converts to the same type. [Example:

```
struct A {
    template <class T> operator T*();
};

template <class T> A::operator T*(){ return 0; }
template <> A::operator char*(){ return 0; } // specialization
```

```

template A::operator void*();           // explicit instantiation

int main() {
    A a;
    int* ip;
    ip = a.operator int*();           // explicit call to template operator A::operator int*()
}

```

— end example] [Note: Because the explicit template argument list follows the function template name, and because conversion member function templates and constructor member function templates are called without using a function name, there is no way to provide an explicit template argument list for these function templates. — end note]

- 6 A specialization of a conversion function template is not found by name lookup. Instead, any conversion function templates visible in the context of the use are considered. For each such operator, if argument deduction succeeds (??), the resulting specialization is used as if found by name lookup.
- 7 A *using-declaration* in a derived class cannot refer to a specialization of a conversion function template in a base class.
- 8 Overload resolution (??) and partial ordering (??) are used to select the best conversion function among multiple specializations of conversion function templates and/or non-template conversion functions.

### 17.6.3 Variadic templates

[temp.variadic]

- 1 A *template parameter pack* is a template parameter that accepts zero or more template arguments. [Example:

```

template<class ... Types> struct Tuple { };

Tuple<> t0;           // Types contains no arguments
Tuple<int> t1;        // Types contains one argument: int
Tuple<int, float> t2; // Types contains two arguments: int and float
Tuple<0> error;       // error: 0 is not a type

— end example]

```

- 2 A *function parameter pack* is a function parameter that accepts zero or more function arguments. [Example:

```

template<class ... Types> void f(Types ... args);

f();                  // OK: args contains no arguments
f(1);                // OK: args contains one argument: int
f(2, 1.0);           // OK: args contains two arguments: int and double

— end example]

```

- 3 A *parameter pack* is either a template parameter pack or a function parameter pack.

- 4 A *pack expansion* consists of a *pattern* and an ellipsis, the instantiation of which produces zero or more instantiations of the pattern in a list (described below). The form of the pattern depends on the context in which the expansion occurs. Pack expansions can occur in the following contexts:

- (4.1) — In a function parameter pack (??); the pattern is the *parameter-declaration* without the ellipsis.
- (4.2) — In a *using-declaration* (??); the pattern is a *using-declarator*.
- (4.3) — In a template parameter pack that is a pack expansion (??):

- (4.3.1) — if the template parameter pack is a *parameter-declaration*; the pattern is the *parameter-declaration* without the ellipsis;
- (4.3.2) — if the template parameter pack is a *type-parameter* with a *template-parameter-list*; the pattern is the corresponding *type-parameter* without the ellipsis.
- (4.4) — In an *initializer-list* (??); the pattern is an *initializer-clause*.
- (4.5) — In a *base-specifier-list* (??); the pattern is a *base-specifier*.
- (4.6) — In a *mem-initializer-list* (??) for a *mem-initializer* whose *mem-initializer-id* denotes a base class; the pattern is the *mem-initializer*.
- (4.7) — In a *template-argument-list* (??); the pattern is a *template-argument*.
- (4.8) — In an *attribute-list* (??); the pattern is an *attribute*.
- (4.9) — In an *alignment-specifier* (??); the pattern is the *alignment-specifier* without the ellipsis.
- (4.10) — In a *capture-list* (??); the pattern is a *capture*.
- (4.11) — In a `sizeof...` expression (??); the pattern is an *identifier*.
- (4.12) — In a *fold-expression* (??); the pattern is the *cast-expression* that contains an unexpanded parameter pack.

[*Example*:

```
template<class ... Types> void f(Types ... rest);
template<class ... Types> void g(Types ... rest) {
    f(&rest ...);      // "&rest ..." is a pack expansion; "&rest" is its pattern
}
```

— *end example*]

- <sup>5</sup> For the purpose of determining whether a parameter pack satisfies a rule regarding entities other than parameter packs, the parameter pack is considered to be the entity that would result from an instantiation of the pattern in which it appears.
- <sup>6</sup> A parameter pack whose name appears within the pattern of a pack expansion is expanded by that pack expansion. An appearance of the name of a parameter pack is only expanded by the innermost enclosing pack expansion. The pattern of a pack expansion shall name one or more parameter packs that are not expanded by a nested pack expansion; such parameter packs are called *unexpanded parameter packs* in the pattern. All of the parameter packs expanded by a pack expansion shall have the same number of arguments specified. An appearance of a name of a parameter pack that is not expanded is ill-formed. [*Example*:

```
template<typename...> struct Tuple {};
template<typename T1, typename T2> struct Pair {};

template<class ... Args1> struct zip {
    template<class ... Args2> struct with {
        typedef Tuple<Pair<Args1, Args2> ... > type;
    };
};

typedef zip<short, int>::with<unsigned short, unsigned>::type T1;
// T1 is Tuple<Pair<short, unsigned short>, Pair<int, unsigned>>
typedef zip<short>::with<unsigned short, unsigned>::type T2;
// error: different number of arguments specified for Args1 and Args2
```

```

template<class ... Args>
void g(Args ... args) {                                // OK: Args is expanded by the function parameter pack args
    f(const_cast<const Args*>(&args)...);           // OK: "Args" and "args" are expanded
    f(5 ...);                                         // error: pattern does not contain any parameter packs
    f(args);                                          // error: parameter pack "args" is not expanded
    f(h(args ...) + args ...);                        // OK: first "args" expanded within h,
                                                    // second "args" expanded within f
}
— end example]

```

- <sup>7</sup> The instantiation of a pack expansion that is neither a `sizeof...` expression nor a *fold-expression* produces a list  $E_1, E_2, \dots, E_N$ , where  $N$  is the number of elements in the pack expansion parameters. Each  $E_i$  is generated by instantiating the pattern and replacing each pack expansion parameter with its  $i$ th element. Such an element, in the context of the instantiation, is interpreted as follows:

- (7.1) — if the pack is a template parameter pack, the element is a template parameter (??) of the corresponding kind (type or non-type) designating the type or value from the template argument; otherwise,
- (7.2) — if the pack is a function parameter pack, the element is an *id-expression* designating the function parameter that resulted from the instantiation of the pattern where the pack is declared.

All of the  $E_i$  become elements in the enclosing list. [ *Note*: The variety of list varies with the context: *expression-list*, *base-specifier-list*, *template-argument-list*, etc. — *end note* ] When  $N$  is zero, the instantiation of the expansion produces an empty list. Such an instantiation does not alter the syntactic interpretation of the enclosing construct, even in cases where omitting the list entirely would otherwise be ill-formed or would result in an ambiguity in the grammar. [ *Example*:

```

template<class... T> struct X : T... { };
template<class... T> void f(T... values) {
    X<T...> x(values...);
}

template void f<>();      // OK: X<> has no base classes
                           // x is a variable of type X<> that is value-initialized

```

- *end example*]
- <sup>8</sup> The instantiation of a `sizeof...` expression (??) produces an integral constant containing the number of elements in the parameter pack it expands.

- <sup>9</sup> The instantiation of a *fold-expression* produces:

- (9.1) —  $((E_1 \ op \ E_2) \ op \ \dots) \ op \ E_N$  for a unary left fold,
- (9.2) —  $E_1 \ op \ (\dots \ op \ (E_{N-1} \ op \ E_N))$  for a unary right fold,
- (9.3) —  $((((E \ op \ E_1) \ op \ E_2) \ op \ \dots) \ op \ E_N)$  for a binary left fold, and
- (9.4) —  $E_1 \ op \ (\dots \ op \ (E_{N-1} \ op \ (E_N \ op \ E)))$  for a binary right fold.

In each case,  $op$  is the *fold-operator*,  $N$  is the number of elements in the pack expansion parameters, and each  $E_i$  is generated by instantiating the pattern and replacing each pack expansion parameter with its  $i$ th element. For a binary fold-expression,  $E$  is generated by instantiating the *cast-expression* that did not contain an unexpanded parameter pack. [ *Example*:

```

template<typename ...Args>
bool all(Args ...args) { return (... && args); }

```

```
bool b = all(true, true, true, false);
```

Within the instantiation of `all`, the returned expression expands to `((true && true) && true) && false`, which evaluates to `false`. — *end example*] If  $N$  is zero for a unary fold-expression, the value of the expression is shown in Table ??; if the operator is not listed in Table ??, the instantiation is ill-formed.

Table 14 — Value of folding empty sequences

Operator	Value when parameter pack is empty
<code>&amp;&amp;</code>	<code>true</code>
<code>  </code>	<code>false</code>
<code>,</code>	<code>void()</code>

#### 17.6.4 Friends

[temp.friend]

- 1 A friend of a class or class template can be a function template or class template, a specialization of a function template or class template, or a non-template function or class. For a friend function declaration that is not a template declaration:
  - (1.1) — if the name of the friend is a qualified or unqualified *template-id*, the friend declaration refers to a specialization of a function template, otherwise,
  - (1.2) — if the name of the friend is a *qualified-id* and a matching non-template function is found in the specified class or namespace, the friend declaration refers to that function, otherwise,
  - (1.3) — if the name of the friend is a *qualified-id* and a matching function template is found in the specified class or namespace, the friend declaration refers to the deduced specialization of that function template (??), otherwise,
  - (1.4) — the name shall be an *unqualified-id* that declares (or redeclares) a non-template function.

[*Example*:

```
template<class T> class task;
template<class T> task<T>* preempt(task<T>*);

template<class T> class task {
    friend void next_time();
    friend void process(task<T>*);
    friend task<T>* preempt<T>(task<T>*);
    template<class C> friend int func(C);

    friend class task<int>;
    template<class P> friend class frd;
};

```

Here, each specialization of the `task` class template has the function `next_time` as a friend; because `process` does not have explicit *template-arguments*, each specialization of the `task` class template has an appropriately typed function `process` as a friend, and this friend is not a function template specialization; because the friend `preempt` has an explicit *template-argument* `T`, each specialization of the `task` class template has the appropriate specialization of the function template `preempt` as a friend; and each specialization of the `task` class template has all specializations of the function template `func` as friends. Similarly, each specialization of the `task` class template has the class template specialization `task<int>` as a friend, and has all specializations of the class template `frd` as friends. — *end example*]

- <sup>2</sup> A friend template may be declared within a class or class template. A friend function template may be defined within a class or class template, but a friend class template may not be defined in a class or class template. In these cases, all specializations of the friend class or friend function template are friends of the class or class template granting friendship. [ *Example*:

```
class A {
    template<class T> friend class B;           // OK
    template<class T> friend void f(T){ /* ... */ } // OK
};

— end example ]
```

- <sup>3</sup> A template friend declaration specifies that all specializations of that template, whether they are implicitly instantiated (??), partially specialized (??) or explicitly specialized (??), are friends of the class containing the template friend declaration. [ *Example*:

```
class X {
    template<class T> friend struct A;
    class Y { };
};

template<class T> struct A { X::Y ab; };           // OK
template<class T> struct A<T*> { X::Y ab; };     // OK

— end example ]
```

- <sup>4</sup> A template friend declaration may declare a member of a dependent type to be a friend. The friend declaration shall declare a function or specify a type with an *elaborated-type-specifier*, in either case with a *nested-name-specifier* ending with a *simple-template-id*, *C*, whose *template-name* names a class template. The template parameters of the template friend declaration shall be deducible from *C* (??). In this case, a member of a specialization *S* of the class template is a friend of the class granting friendship if deduction of the template parameters of *C* from *S* succeeds, and substituting the deduced template arguments into the friend declaration produces a declaration that would be a valid redeclaration of the member of the specialization. [ *Example*:

```
template<class T> struct A {
    struct B { };
    void f();
    struct D {
        void g();
    };
    T h();
    template<T U> T i();
};

template<> struct A<int> {
    struct B { };
    int f();
    struct D {
        void g();
    };
    template<int U> int i();
};
```

```

template<> struct A<float*> {
    int *h();
};

class C {
    template<class T> friend struct A<T>::B;           // grants friendship to A<int>::B even though
    template<class T> friend void A<T>::f();           // it is not a specialization of A<T>::B
    template<class T> friend void A<T>::D::g();         // does not grant friendship to A<int>::f()
    template<class T> friend int *A<T*>::h();          // because its return type does not match
    template<class T> template<T U>                   // ill-formed: A<T>::D does not end with
        friend T A<T>::i();                           // a simple-template-id
};                                                       // grants friendship to A<int*>::h() and A<float*>::h()
                                                       // grants friendship to instantiations of A<T>::i() and
                                                       // to A<int>::i(), and thereby to all specializations
                                                       // of those function templates

— end example ]

```

5 [ Note: A friend declaration may first declare a member of an enclosing namespace scope (??). — end note ]

6 A friend template shall not be declared in a local class.

7 Friend declarations shall not declare partial specializations. [ Example:

```

template<class T> class A {};
class X {
    template<class T> friend class A<T*>;           // error
};

— end example ]

```

8 When a friend declaration refers to a specialization of a function template, the function parameter declarations shall not include default arguments, nor shall the inline specifier be used in such a declaration.

9 A non-template friend declaration shall not have a *requires-clause*.

### 17.6.5 Class template partial specializations

[temp.class.spec]

- 1 A *primary class template* declaration is one in which the class template name is an identifier. A template declaration in which the class template name is a *simple-template-id* is a *partial specialization* of the class template named in the *simple-template-id*. A partial specialization of a class template provides an alternative definition of the template that is used instead of the primary definition when the arguments in a specialization match those given in the partial specialization (??). The primary template shall be declared before any specializations of that template. A partial specialization shall be declared before the first use of a class template specialization that would make use of the partial specialization as the result of an implicit or explicit instantiation in every translation unit in which such a use occurs; no diagnostic is required.
- 2 Each class template partial specialization is a distinct template and definitions shall be provided for the members of a template partial specialization (??).
- 3 [ Example:

```

template<class T1, class T2, int I> class A           { };
template<class T, int I>             class A<T, T*, I> { };
template<class T1, class T2, int I> class A<T1*, T2, I> { };
template<class T>                 class A<int, T*, 5> { };
template<class T1, class T2, int I> class A<T1, T2*, I> { };

```

The first declaration declares the primary (unspecialized) class template. The second and subsequent declarations declare partial specializations of the primary template. — *end example*]

- <sup>4</sup> A class template partial specialization may be constrained (??). [ *Example*:

```
template<typename T> concept C = true;

template<typename T> struct X { };
template<typename T> struct X<T*> { };           // #1
template<C T> struct X<T> { };                 // #2
```

Both partial specializations are more specialized than the primary template. #1 is more specialized because the deduction of its template arguments from the template argument list of the class template specialization succeeds, while the reverse does not. #2 is more specialized because the template arguments are equivalent, but the partial specialization is more constrained (??). — *end example*]

- <sup>5</sup> The template parameters are specified in the angle bracket enclosed list that immediately follows the keyword `template`. For partial specializations, the template argument list is explicitly written immediately following the class template name. For primary templates, this list is implicitly described by the template parameter list. Specifically, the order of the template arguments is the sequence in which they appear in the template parameter list. [ *Example*: The template argument list for the primary template in the example above is `<T1, T2, I>`. — *end example*] [ *Note*: The template argument list shall not be specified in the primary template declaration. For example,

```
template<class T1, class T2, int I>
class A<T1, T2, I> { };                      // error
— end note]
```

- <sup>6</sup> A class template partial specialization may be declared in any scope in which the corresponding primary template may be defined (??, ??, ??). [ *Example*:

```
template<class T> struct A {
    struct C {
        template<class T2> struct B { };
        template<class T2> struct B<T2**> { };      // partial specialization #1
    };
};

// partial specialization of A<T>::C::B<T2>
template<class T> template<class T2>
struct A<T>::C::B<T2*> { };                  // #2

A<short>::C::B<int*> absip;                // uses partial specialization #2
— end example]
```

- <sup>7</sup> Partial specialization declarations themselves are not found by name lookup. Rather, when the primary template name is used, any previously-declared partial specializations of the primary template are also considered. One consequence is that a *using-declaration* which refers to a class template does not restrict the set of partial specializations which may be found through the *using-declaration*. [ *Example*:

```
namespace N {
    template<class T1, class T2> class A { };      // primary template
}
```

```

using N::A;                                // refers to the primary template

namespace N {
    template<class T> class A<T, T*> { };      // partial specialization
}

A<int,int*> a;        // uses the partial specialization, which is found through the using-declaration
                        // which refers to the primary template
— end example]

```

<sup>8</sup> A non-type argument is non-specialized if it is the name of a non-type parameter. All other non-type arguments are specialized.

<sup>9</sup> Within the argument list of a class template partial specialization, the following restrictions apply:

- (9.1) — The type of a template parameter corresponding to a specialized non-type argument shall not be dependent on a parameter of the specialization. [Example:

```

template <class T, T t> struct C {};
template <class T> struct C<T, 1>;           // error

template< int X, int (*array_ptr)[X] > class A {};
int array[5];
template< int X > class A<X,&array> { };       // error
— end example]

```

- (9.2) — The specialization shall be more specialized than the primary template (??).

- (9.3) — The template parameter list of a specialization shall not contain default template argument values.<sup>141</sup>

- (9.4) — An argument shall not contain an unexpanded parameter pack. If an argument is a pack expansion (??), it shall be the last argument in the template argument list.

- <sup>10</sup> The usual access checking rules do not apply to non-dependent names used to specify template arguments of the *simple-template-id* of the partial specialization. [Note: The template arguments may be private types or objects that would normally not be accessible. Dependent names cannot be checked when declaring the partial specialization, but will be checked when substituting into the partial specialization. — end note]

### 17.6.5.1 Matching of class template partial specializations

[temp.class.spec.match]

<sup>1</sup> When a class template is used in a context that requires an instantiation of the class, it is necessary to determine whether the instantiation is to be generated using the primary template or one of the partial specializations. This is done by matching the template arguments of the class template specialization with the template argument lists of the partial specializations.

- (1.1) — If exactly one matching specialization is found, the instantiation is generated from that specialization.
- (1.2) — If more than one matching specialization is found, the partial order rules (??) are used to determine whether one of the specializations is more specialized than the others. If none of the specializations is more specialized than all of the other matching specializations, then the use of the class template is ambiguous and the program is ill-formed.
- (1.3) — If no matches are found, the instantiation is generated from the primary template.

<sup>141</sup>) There is no way in which they could be used.

- <sup>2</sup> A partial specialization matches a given actual template argument list if the template arguments of the partial specialization can be deduced from the actual template argument list (??), and the deduced template arguments satisfy the associated constraints of the partial specialization, if any (??). [Example:

```
template<class T1, class T2, int I> class A { }; // #1
template<class T, int I> class A<T, T*, I> { }; // #2
template<class T1, class T2, int I> class A<T1*, T2, I> { }; // #3
template<class T> class A<int, T*, 5> { }; // #4
template<class T1, class T2, int I> class A<T1, T2*, I> { }; // #5

A<int, int, 1> a1; // uses #1
A<int, int*, 1> a2; // uses #2, T is int, I is 1
A<int, char*, 5> a3; // uses #4, T is char
A<int, char*, 1> a4; // uses #5, T1 is int, T2 is char, I is 1
A<int*, int*, 2> a5; // ambiguous: matches #3 and #5
```

— end example] [Example:

```
template<typename T> concept C = requires (T t) { t.f(); };

template<typename T> struct S { }; // #1
template<C T> struct S<T> { }; // #2

struct Arg { void f(); };

S<int> s1; // uses #1; the constraints of #2 are not satisfied
S<Arg> s2; // uses #2; both constraints are satisfied but #2 is more specialized
```

— end example]

- <sup>3</sup> If the template arguments of a partial specialization cannot be deduced because of the structure of its *template-parameter-list* and the *template-id*, the program is ill-formed. [Example:

```
template <int I, int J> struct A {};
template <int I> struct A<I+5, I*2> {}; // error

template <int I> struct A<I, I> {}; // OK

template <int I, int J, int K> struct B {};
template <int I> struct B<I, I*2, 2> {}; // OK
```

— end example]

- <sup>4</sup> In a type name that refers to a class template specialization, (e.g., A<int, int, 1>) the argument list shall match the template parameter list of the primary template. The template arguments of a specialization are deduced from the arguments of the primary template.

### 17.6.5.2 Partial ordering of class template specializations

[temp.class.order]

- <sup>1</sup> For two class template partial specializations, the first is *more specialized* than the second if, given the following rewrite to two function templates, the first function template is more specialized than the second according to the ordering rules for function templates (??):

- (1.1) — Each of the two function templates has the same template parameters and associated constraints (??) as the corresponding partial specialization.

- (1.2) — Each function template has a single function parameter whose type is a class template specialization where the template arguments are the corresponding template parameters from the function template for each template argument in the *template-argument-list* of the *simple-template-id* of the partial specialization.

<sup>2</sup> [ *Example*:

```
template<int I, int J, class T> class X { };
template<int I, int J>           class X<I, J, int> { };           // #1
template<int I>                class X<I, I, int> { };           // #2

template<int I0, int J0> void f(X<I0, J0, int>);                  // A
template<int I0>               void f(X<I0, I0, int>);           // B

template <auto v>   class Y { };
template <auto* p>  class Y<p> { };                                // #3
template <auto** pp> class Y<pp> { };                            // #4

template <auto* p0>  void g(Y<p0>);                                // C
template <auto** pp0> void g(Y<pp0>);                           // D
```

According to the ordering rules for function templates, the function template *B* is more specialized than the function template *A* and the function template *D* is more specialized than the function template *C*. Therefore, the partial specialization #2 is more specialized than the partial specialization #1 and the partial specialization #4 is more specialized than the partial specialization #3. — *end example*] [ *Example*:

```
template<typename T> concept C = requires (T t) { t.f(); };
template<typename T> concept D = C<T> && requires (T t) { t.f(); };

template<typename T> class S { };
template<C T> class S<T> { }; // #1
template<D T> class S<T> { }; // #2

template<C T> void f(S<T>);    // A
template<D T> void f(S<T>);    // B
```

The partial specialization #2 is more specialized than #1 because *B* is more specialized than *A*. — *end example*]

### 17.6.5.3 Members of class template specializations

[temp.class.spec.mfunc]

- <sup>1</sup> The template parameter list of a member of a class template partial specialization shall match the template parameter list of the class template partial specialization. The template argument list of a member of a class template partial specialization shall match the template argument list of the class template partial specialization. A class template specialization is a distinct template. The members of the class template partial specialization are unrelated to the members of the primary template. Class template partial specialization members that are used in a way that requires a definition shall be defined; the definitions of members of the primary template are never used as definitions for members of a class template partial specialization. An explicit specialization of a member of a class template partial specialization is declared in the same way as an explicit specialization of the primary template. [ *Example*:

```
// primary class template
template<class T, int I> struct A {
```

```

void f();
};

// member of primary class template
template<class T, int I> void A<T,I>::f() { }

// class template partial specialization
template<class T> struct A<T,2> {
    void f();
    void g();
    void h();
};

// member of class template partial specialization
template<class T> void A<T,2>::g() { }

// explicit specialization
template<> void A<char,2>::h() { }

int main() {
    A<char,0> a0;
    A<char,2> a2;
    a0.f();           // OK, uses definition of primary template's member
    a2.g();           // OK, uses definition of partial specialization's member
    a2.h();           // OK, uses definition of explicit specialization's member
    a2.f();           // ill-formed, no definition of f for A<T,2>; the primary template is not used here
}
— end example]

```

- <sup>2</sup> If a member template of a class template is partially specialized, the member template partial specializations are member templates of the enclosing class template; if the enclosing class template is instantiated (??, ??), a declaration for every member template partial specialization is also instantiated as part of creating the members of the class template specialization. If the primary member template is explicitly specialized for a given (implicit) specialization of the enclosing class template, the partial specializations of the member template are ignored for this specialization of the enclosing class template. If a partial specialization of the member template is explicitly specialized for a given (implicit) specialization of the enclosing class template, the primary member template and its other partial specializations are still considered for this specialization of the enclosing class template. [Example:

```

template<class T> struct A {
    template<class T2> struct B {};<                                // #1
    template<class T2> struct B<T2*> {};<                            // #2
};

template<> template<class T2> struct A<short>::B {};< // #3

A<char>::B<int*> abcip;                                // uses #2
A<short>::B<int*> absip;                                // uses #3
A<char>::B<int> abci;                                    // uses #1

```

— end example ]

## 17.6.6 Function templates

[temp.fct]

- <sup>1</sup> A function template defines an unbounded set of related functions. [ *Example:* A family of sort functions might be declared like this:

```
template<class T> class Array { };
template<class T> void sort(Array<T>&);

— end example ]
```

- <sup>2</sup> A function template can be overloaded with other function templates and with non-template functions (??). A non-template function is not related to a function template (i.e., it is never considered to be a specialization), even if it has the same name and type as a potentially generated function template specialization.<sup>142</sup>

### 17.6.6.1 Function template overloading

[temp.over.link]

- <sup>1</sup> It is possible to overload function templates so that two different function template specializations have the same type. [ *Example:*

```
// translation unit 1:                                // translation unit 2:
template<class T>
void f(T*);                                         void f(T);
void g(int* p) {
    f(p); // calls f<int>(int*)                  void h(int* p) {
}                                                       f(p); // calls f<int*>(int*)
}

— end example ]
```

- <sup>2</sup> Such specializations are distinct functions and do not violate the one-definition rule (??).

- <sup>3</sup> The signature of a function template is defined in ???. The names of the template parameters are significant only for establishing the relationship between the template parameters and the rest of the signature. [ *Note:* Two distinct function templates may have identical function return types and function parameter lists, even if overload resolution alone cannot distinguish them.

```
template<class T> void f();
template<int I> void f();      // OK: overloads the first template
                               // distinguishable with an explicit template argument list
```

— end note ]

- <sup>4</sup> When an expression that references a template parameter is used in the function parameter list or the return type in the declaration of a function template, the expression that references the template parameter is part of the signature of the function template. This is necessary to permit a declaration of a function template in one translation unit to be linked with another declaration of the function template in another translation unit and, conversely, to ensure that function templates that are intended to be distinct are not linked with one another. [ *Example:*

```
template <int I, int J> A<I+J> f(A<I>, A<J>); // #1
template <int K, int L> A<K+L> f(A<K>, A<L>); // same as #1
template <int I, int J> A<I-J> f(A<I>, A<J>); // different from #1
```

---

<sup>142)</sup> That is, declarations of non-template functions do not merely guide overload resolution of function template specializations with the same name. If such a non-template function is odr-used (??) in a program, it must be defined; it will not be implicitly instantiated using the function template definition.

— end example] [ Note: Most expressions that use template parameters use non-type template parameters, but it is possible for an expression to reference a type parameter. For example, a template type parameter can be used in the `sizeof` operator. — end note]

- 5 Two expressions involving template parameters are considered *equivalent* if two function definitions containing the expressions would satisfy the one-definition rule (??), except that the tokens used to name the template parameters may differ as long as a token used to name a template parameter in one expression is replaced by another token that names the same template parameter in the other expression. Two *lambda-expressions* are never considered equivalent. [ Note: The intent is to avoid *lambda-expressions* appearing in the signature of a function template with external linkage. — end note] For determining whether two dependent names (??) are equivalent, only the name itself is considered, not the result of name lookup in the context of the template. If multiple declarations of the same function template differ in the result of this name lookup, the result for the first declaration is used. [ Example:

```
template <int I, int J> void f(A<I+J>);           // #1
template <int K, int L> void f(A<K+L>);           // same as #1

template <class T> decltype(g(T())) h();           // redeclaration of h() uses the earlier lookup...
int g(int);                                         // ... although the lookup here does find g(int)
template <class T> decltype(g(T())) h()             // template argument substitution fails; g(int)
{ return g(T()); }                                // was not in scope at the first declaration of h()

// ill-formed, no diagnostic required: the two expressions are functionally equivalent but not equivalent
template <int N> void foo(const char (*s)[(][], N));
template <int N> void foo(const char (*s)[(][], N));

// two different declarations because the non-dependent portions are not considered equivalent
template <class T> void spam(decltype([]{}) (*s)[sizeof(T)]);
template <class T> void spam(decltype([]{}) (*s)[sizeof(T)]);
```

— end example] Two expressions involving template parameters that are not equivalent are *functionally equivalent* if, for any given set of template arguments, the evaluation of the expression results in the same value.

- 6 Two *template-heads* are *equivalent* if their *template-parameter-lists* have the same length, corresponding *template-parameters* are equivalent, and if either has a *requires-clause*, they both have *requires-clauses* and the corresponding *constraint-expressions* are equivalent. Two *template-parameters* are *equivalent* under the following conditions:

- (6.1) — they declare template parameters of the same kind,
- (6.2) — if either declares a template parameter pack, they both do,
- (6.3) — if they declare non-type template parameters, they have equivalent types,
- (6.4) — if they declare template template parameters, their template parameters are equivalent, and
- (6.5) — if either is declared with a *qualified-concept-name*, they both are, and the *qualified-concept-names* are equivalent.

When determining whether types or *qualified-concept-names* are equivalent, the rules above are used to compare expressions involving template parameters. Two *template-heads* are *functionally equivalent* if they

accept and are satisfied by (??) the same set of template argument lists.

- 7 Two function templates are *equivalent* if they are declared in the same scope, have the same name, have equivalent *template-heads*, and have return types, parameter lists, and trailing *requires-clauses* (if any) that are equivalent using the rules described above to compare expressions involving template parameters. Two function templates are *functionally equivalent* if they are declared in the same scope, have the same name, accept and are satisfied by the same set of template argument lists, and have return types and parameter lists that are functionally equivalent using the rules described above to compare expressions involving template parameters. If the validity or meaning of the program depends on whether two constructs are equivalent, and they are functionally equivalent but not equivalent, the program is ill-formed, no diagnostic required.
- 8 [ *Note*: This rule guarantees that equivalent declarations will be linked with one another, while not requiring implementations to use heroic efforts to guarantee that functionally equivalent declarations will be treated as distinct. For example, the last two declarations are functionally equivalent and would cause a program to be ill-formed:

```
// guaranteed to be the same
template <int I> void f(A<I>, A<I+10>);
template <int I> void f(A<I>, A<I+10>);

// guaranteed to be different
template <int I> void f(A<I>, A<I+10>);
template <int I> void f(A<I>, A<I+11>);

// ill-formed, no diagnostic required
template <int I> void f(A<I>, A<I+10>);
template <int I> void f(A<I>, A<I+1+2+3+4>);

— end note ]
```

#### 17.6.6.2 Partial ordering of function templates

[temp.func.order]

- 1 If a function template is overloaded, the use of a function template specialization might be ambiguous because template argument deduction (??) may associate the function template specialization with more than one function template declaration. *Partial ordering* of overloaded function template declarations is used in the following contexts to select the function template to which a function template specialization refers:
  - (1.1) — during overload resolution for a call to a function template specialization (??);
  - (1.2) — when the address of a function template specialization is taken;
  - (1.3) — when a placement operator delete that is a function template specialization is selected to match a placement operator new (??, ??);
  - (1.4) — when a friend function declaration (??), an explicit instantiation (??) or an explicit specialization (??) refers to a function template specialization.
- 2 Partial ordering selects which of two function templates is more specialized than the other by transforming each template in turn (see next paragraph) and performing template argument deduction using the function type. The deduction process determines whether one of the templates is more specialized than the other. If so, the more specialized template is the one chosen by the partial ordering process. If both deductions succeed, the partial ordering selects the more constrained template as described by the rules in ??.
- 3 To produce the transformed template, for each type, non-type, or template template parameter (including template parameter packs (??) thereof) synthesize a unique type, value, or class template respectively and

substitute it for each occurrence of that parameter in the function type of the template. [ *Note:* The type replacing the placeholder in the type of the value synthesized for a non-type template parameter is also a unique synthesized type. — *end note* ] If only one of the function templates  $M$  is a non-static member of some class  $A$ ,  $M$  is considered to have a new first parameter inserted in its function parameter list. Given  $cv$  as the cv-qualifiers of  $M$  (if any), the new parameter is of type “rvalue reference to  $cv A$ ” if the optional *ref-qualifier* of  $M$  is `&&` or if  $M$  has no *ref-qualifier* and the first parameter of the other template has rvalue reference type. Otherwise, the new parameter is of type “lvalue reference to  $cv A$ ”. [ *Note:* This allows a non-static member to be ordered with respect to a non-member function and for the results to be equivalent to the ordering of two equivalent non-members. — *end note* ] [ *Example:* ]

```
struct A { };
template<class T> struct B {
    template<class R> int operator*(R&); // #1
};

template<class T, class R> int operator*(T&, R&); // #2

// The declaration of B::operator* is transformed into the equivalent of
// template<class R> int operator*(B<A>&, R&); // #1a

int main() {
    A a;
    B<A> b;
    b * a; // calls #1a
}
```

— *end example* ]

- <sup>4</sup> Using the transformed function template’s function type, perform type deduction against the other template as described in ??.

[ *Example:* ]

```
template<class T> struct A { A(); };

template<class T> void f(T);
template<class T> void f(T*);
template<class T> void f(const T*);

template<class T> void g(T);
template<class T> void g(T&);

template<class T> void h(const T&);
template<class T> void h(A<T>&);

void m() {
    const int* p;
    f(p); // f(const T*) is more specialized than f(T) or f(T*)
    float x;
    g(x); // ambiguous: g(T) or g(T&)
    A<int> z;
    h(z); // overload resolution selects h(A<T>&)
```

```

    const A<int> z2;
    h(z2);           // h(const T&) is called because h(A<T>&) is not callable
}
— end example]

```

- <sup>5</sup> [Note: Since partial ordering in a call context considers only parameters for which there are explicit call arguments, some parameters are ignored (namely, function parameter packs, parameters with default arguments, and ellipsis parameters). [Example:

```

template<class T> void f(T);           // #1
template<class T> void f(T*, int=1);   // #2
template<class T> void g(T);           // #3
template<class T> void g(T*, ...);     // #4

int main() {
    int* ip;
    f(ip);                  // calls #2
    g(ip);                  // calls #4
}

```

— end example] [Example:

```

template<class T, class U> struct A { };

template<class T, class U> void f(U, A<U, T*>* p = 0); // #1
template<class T, class U> void f(U, A<U, U*>* p = 0); // #2
template<class T> void g(T, T = T());                   // #3
template<class T, class... U> void g(T, U ...);          // #4

void h() {
    f<int>(42, (A<int, int>*)0);                      // calls #2
    f<int>(42);                                         // error: ambiguous
    g(42);                                              // error: ambiguous
}

```

— end example] [Example:

```

template<class T, class... U> void f(T, U...);           // #1
template<class T> void f(T);                           // #2
template<class T, class... U> void g(T*, U...);         // #3
template<class T> void g(T);                          // #4

void h(int i) {
    f(&i);                                         // error: ambiguous
    g(&i);                                         // OK: calls #3
}

```

— end example] — end note]

### 17.6.7 Alias templates

[temp.alias]

- <sup>1</sup> A *template-declaration* in which the *declaration* is an *alias-declaration* (??) declares the *identifier* to be an *alias template*. An alias template is a name for a family of types. The name of the alias template is a *template-name*.

- <sup>2</sup> When a *template-id* refers to the specialization of an alias template, it is equivalent to the associated type obtained by substitution of its *template-arguments* for the *template-parameters* in the *type-id* of the alias template. [ *Note*: An alias template name is never deduced. — *end note* ] [ *Example*:

```
template<class T> struct Alloc { /* ... */ };
template<class T> using Vec = vector<T, Alloc<T>>;
Vec<int> v;           // same as vector<int, Alloc<int>> v;

template<class T>
void process(Vec<T>& v)
{ /* ... */ }

template<class T>
void process(vector<T, Alloc<T>>& w)
{ /* ... */ }      // error: redefinition

template<template<class> class TT>
void f(TT<int>);

f(v);               // error: Vec not deduced

template<template<class, class> class TT>
void g(TT<int, Alloc<int>>);
g(v);               // OK: TT = vector
```

— *end example* ]

- <sup>3</sup> However, if the *template-id* is dependent, subsequent template argument substitution still applies to the *template-id*. [ *Example*:

```
template<typename...> using void_t = void;
template<typename T> void_t<typename T::foo> f();
f<int>();           // error, int does not have a nested type foo
— end example ]
```

- <sup>4</sup> The *type-id* in an alias template declaration shall not refer to the alias template being declared. The type produced by an alias template specialization shall not directly or indirectly make use of that specialization. [ *Example*:

```
template <class T> struct A;
template <class T> using B = typename A<T>::U;
template <class T> struct A {
    typedef B<T> U;
};
B<short> b;           // error: instantiation of B<short> uses own type via A<short>::U
— end example ]
```

- <sup>5</sup> The type of a lambda expression appearing in an alias template declaration is different between instantiations of that template, even when the lambda expression is not dependent. [ *Example*:

```
template <class T>
using A = decltype([] { });
// A<int> and A<char> refer to different closure types
— end example ]
```

### 17.6.8 Concept definitions

[temp.concept]

- <sup>1</sup> A *concept* is a template that defines constraints on its template arguments.
- <sup>2</sup> A *concept-definition* declares a concept. Its *identifier* becomes a *concept-name* referring to that concept within its scope. [ *Example*:

```
template<typename T>
concept C = requires(T x) {
    { x == x } -> bool;
};

template<typename T>
requires C<T>      // C constrains f1(T) in constraint-expression
T f1(T x) { return x; }

template<C T>        // C constrains f2(T) as a constrained-parameter
T f2(T x) { return x; }

— end example ]
```

- <sup>3</sup> A *concept-definition* shall appear at namespace scope (??).
- <sup>4</sup> A concept shall not have associated constraints (??).
- <sup>5</sup> A concept is not instantiated (??). A program that explicitly instantiates (??), explicitly specializes (??), or partially specializes a concept is ill-formed. [ *Note*: An *id-expression* that denotes a concept specialization is evaluated as an expression (??). — end note ]
- <sup>6</sup> The first declared template parameter of a concept definition is its *prototype parameter*. A *variadic concept* is a concept whose prototype parameter is a template parameter pack.

### 17.7 Name resolution

[temp.res]

- <sup>1</sup> Three kinds of names can be used within a template definition:
  - (1.1) — The name of the template itself, and names declared within the template itself.
  - (1.2) — Names dependent on a *template-parameter* (??).
  - (1.3) — Names from scopes which are visible within the template definition.
- <sup>2</sup> A name used in a template declaration or definition and that is dependent on a *template-parameter* is assumed not to name a type unless the applicable name lookup finds a type name or the name is qualified by the keyword **typename**. [ *Example*:

```
// no B declared here

class X;

template<class T> class Y {
    class Z;           // forward declaration of member class

    void f() {
        X* a1;          // declare pointer to X
        T* a2;          // declare pointer to T
        Y* a3;          // declare pointer to Y<T>
        Z* a4;          // declare pointer to Z
```

```

typedef typename T::A TA;
TA* a5;                                // declare pointer to T's A
typename T::A* a6;                      // declare pointer to T's A
T::A* a7;                                // T::A is not a type name:
                                         // multiplication of T::A by a7; ill-formed, no visible declaration of a7
B* a8;                                // B is not a type name:
                                         // multiplication of B by a8; ill-formed, no visible declarations of B and a8
}
};

— end example]

```

- 3 When a *qualified-id* is intended to refer to a type that is not a member of the current instantiation (??) and its *nested-name-specifier* refers to a dependent type, it shall be prefixed by the keyword `typename`, forming a *typename-specifier*. If the *qualified-id* in a *typename-specifier* does not denote a type or a class template, the program is ill-formed.

*typename-specifier*:

```

typename nested-name-specifier identifier
typename nested-name-specifier templateopt simple-template-id

```

- 4 If a specialization of a template is instantiated for a set of *template-arguments* such that the *qualified-id* prefixed by `typename` does not denote a type or a class template, the specialization is ill-formed. The usual qualified name lookup (??) is used to find the *qualified-id* even in the presence of `typename`. [Example:

```

struct A {
    struct X { };
    int X;
};

struct B {
    struct X { };
};

template<class T> void f(T t) {
    typename T::X x;
}

void foo() {
    A a;
    B b;
    f(b);           // OK: T::X refers to B::X
    f(a);           // error: T::X refers to the data member A::X not the struct A::X
}

```

— end example]

- 5 A qualified name used as the name in a *class-or-decltype* (??) or an *elaborated-type-specifier* is implicitly assumed to name a type, without the use of the `typename` keyword. In a *nested-name-specifier* that immediately contains a *nested-name-specifier* that depends on a template parameter, the *identifier* or *simple-template-id* is implicitly assumed to name a type, without the use of the `typename` keyword. [Note: The `typename` keyword is not permitted by the syntax of these constructs. — end note]
- 6 If, for a given set of template arguments, a specialization of a template is instantiated that refers to a *qualified-id* that denotes a type or a class template, and the *qualified-id* refers to a member of an unknown specialization, the *qualified-id* shall either be prefixed by `typename` or shall be used in a context in which it implicitly names a type as described above. [Example:

```

template <class T> void f(int i) {
    T::x * i;           // T::x must not be a type
}

struct Foo {
    typedef int x;
};

struct Bar {
    static int const x = 5;
};

int main() {
    f<Bar>(1);        // OK
    f<Foo>(1);        // error: Foo::x is a type
}

```

— end example]

- <sup>7</sup> Within the definition of a class template or within the definition of a member of a class template following the *declarator-id*, the keyword `typename` is not required when referring to the name of a previously declared member of the class template that declares a type or a class template. [ *Note:* Such names can be found using unqualified name lookup (??), class member lookup (??) into the current instantiation (??), or class member access expression lookup (??) when the type of the object expression is the current instantiation (??). — end note] [ *Example:*

```

template<class T> struct A {
    typedef int B;
    B b;             // OK, no typename required
};

```

— end example]

- <sup>8</sup> Knowing which names are type names allows the syntax of every template to be checked. The program is ill-formed, no diagnostic required, if:

- (8.1) — no valid specialization can be generated for a template or a substatement of a `constexpr` if statement (??) within a template and the template is not instantiated, or
- (8.2) — no substitution of template arguments into a *partial-concept-id* or *requires-clause* would result in a valid expression, or
- (8.3) — every valid specialization of a variadic template requires an empty template parameter pack, or
- (8.4) — a hypothetical instantiation of a template immediately following its definition would be ill-formed due to a construct that does not depend on a template parameter, or
- (8.5) — the interpretation of such a construct in the hypothetical instantiation is different from the interpretation of the corresponding construct in any actual instantiation of the template. [ *Note:* This can happen in situations including the following:
  - (8.5.1) — a type used in a non-dependent name is incomplete at the point at which a template is defined but is complete at the point at which an instantiation is performed, or

- (8.5.2) — lookup for a name in the template definition found a *using-declaration*, but the lookup in the corresponding scope in the instantiation does not find any declarations because the *using-declaration* was a pack expansion and the corresponding pack is empty, or
  - (8.5.3) — an instantiation uses a default argument or default template argument that had not been defined at the point at which the template was defined, or
  - (8.5.4)
    - constant expression evaluation (??) within the template instantiation uses
      - (8.5.4.1) — the value of a const object of integral or unscoped enumeration type or
      - (8.5.4.2) — the value of a **constexpr** object or
      - (8.5.4.3) — the value of a reference or
      - (8.5.4.4) — the definition of a **constexpr** function,

and that entity was not defined when the template was defined, or
  - (8.5.5) — a class template specialization or variable template specialization that is specified by a non-dependent *simple-template-id* is used by the template, and either it is instantiated from a partial specialization that was not defined when the template was defined or it names an explicit specialization that was not declared when the template was defined.
- *end note*]

Otherwise, no diagnostic shall be issued for a template for which a valid specialization can be generated.  
 [ *Note*: If a template is instantiated, errors will be diagnosed according to the other rules in this document. Exactly when these errors are diagnosed is a quality of implementation issue. — *end note* ] [ *Example*:

```
int j;
template<class T> class X {
    void f(T t, int i, char* p) {
        t = i;           // diagnosed if X::f is instantiated, and the assignment to t is an error
        p = i;           // may be diagnosed even if X::f is not instantiated
        p = j;           // may be diagnosed even if X::f is not instantiated
    }
    void g(T t) {
        +;              // may be diagnosed even if X::g is not instantiated
    }
};

template<class... T> struct A {
    void operator++(int, T... t);           // error: too many parameters
};
template<class... T> union X : T... { };     // error: union with base class
template<class... T> struct A : T..., T... { }; // error: duplicate base class
```

— *end example*]

<sup>9</sup> When looking for the declaration of a name used in a template definition, the usual lookup rules (??, ??) are used for non-dependent names. The lookup of names dependent on the template parameters is postponed until the actual template argument is known (??). [ *Example*:

```
#include <iostream>
using namespace std;
```

```
template<class T> class Set {
    T* p;
    int cnt;
public:
    Set();
    Set<T>(const Set<T>&);
    void printall() {
        for (int i = 0; i < cnt; i++)
            cout << p[i] << '\n';
    }
};
```

in the example, `i` is the local variable `i` declared in `printall`, `cnt` is the member `cnt` declared in `Set`, and `cout` is the standard output stream declared in `iostream`. However, not every declaration can be found this way; the resolution of some names must be postponed until the actual *template-arguments* are known. For example, even though the name `operator<<` is known within the definition of `printall()` and a declaration of it can be found in `<iostream>`, the actual declaration of `operator<<` needed to print `p[i]` cannot be known until it is known what type `T` is (??). — *end example*]

- <sup>10</sup> If a name does not depend on a *template-parameter* (as defined in ??), a declaration (or set of declarations) for that name shall be in scope at the point where the name appears in the template definition; the name is bound to the declaration (or declarations) found at that point and this binding is not affected by declarations that are visible at the point of instantiation. [ *Example*:

```
void f(char);

template<class T> void g(T t) {
    f(1);           // f(char)
    f(T(1));       // dependent
    f(t);          // dependent
    dd++;          // not dependent; error: declaration for dd not found
}

enum E { e };
void f(E);

double dd;
void h() {
    g(e);          // will cause one call of f(char) followed by two calls of f(E)
    g('a');        // will cause three calls of f(char)
}
```

— *end example*]

- <sup>11</sup> [ *Note*: For purposes of name lookup, default arguments and *noexcept-specifiers* of function templates and default arguments and *noexcept-specifiers* of member functions of class templates are considered definitions (??). — *end note*]

### 17.7.1 Locally declared names

[**temp.local**]

- <sup>1</sup> Like normal (non-template) classes, class templates have an injected-class-name (??). The injected-class-name can be used as a *template-name* or a *type-name*. When it is used with a *template-argument-list*, as a *template-argument* for a template *template-parameter*, or as the final identifier in the *elaborated-type-specifier*

of a friend class template declaration, it refers to the class template itself. Otherwise, it is equivalent to the *template-name* followed by the *template-parameters* of the class template enclosed in <>.

- 2 Within the scope of a class template specialization or partial specialization, when the injected-class-name is used as a *type-name*, it is equivalent to the *template-name* followed by the *template-arguments* of the class template specialization or partial specialization enclosed in <>. [Example:

```
template<template<class> class T> class A { };
template<class T> class Y;
template<> class Y<int> {
    Y* p;                                // meaning Y<int>
    Y<char>* q;                          // meaning Y<char>
    A<Y>* a;                            // meaning A<::Y>
    class B {
        template<class> friend class Y;    // meaning ::Y
    };
};

— end example]
```

- 3 The injected-class-name of a class template or class template specialization can be used either as a *template-name* or a *type-name* wherever it is in scope. [Example:

```
template <class T> struct Base {
    Base* p;
};

template <class T> struct Derived: public Base<T> {
    typename Derived::Base* p;           // meaning Derived::Base<T>
};

template<class T, template<class> class U = T::template Base> struct Third { };
Third<Base<int> > t;                  // OK: default argument uses injected-class-name as a template

— end example]
```

- 4 A lookup that finds an injected-class-name (??) can result in an ambiguity in certain cases (for example, if it is found in more than one base class). If all of the injected-class-names that are found refer to specializations of the same class template, and if the name is used as a *template-name*, the reference refers to the class template itself and not a specialization thereof, and is not ambiguous. [Example:

```
template <class T> struct Base { };
template <class T> struct Derived: Base<int>, Base<char> {
    typename Derived::Base b;           // error: ambiguous
    typename Derived::Base<double> d;   // OK
};

— end example]
```

- 5 When the normal name of the template (i.e., the name from the enclosing scope, not the injected-class-name) is used, it always refers to the class template itself and not a specialization of the template. [Example:

```
template<class T> class X {
    X* p;                                // meaning X<T>
    X<T>* p2;
    X<int>* p3;
```

```

::X* p4;                                // error: missing template argument list
                                         // ::X does not refer to the injected-class-name
};

— end example]

```

- 6 A *template-parameter* shall not be redeclared within its scope (including nested scopes). A *template-parameter* shall not have the same name as the template name. [Example:

```

template<class T, int i> class Y {
    int T;                                // error: template-parameter redeclared
    void f() {
        char T;                            // error: template-parameter redeclared
    }
};

template<class X> class X;                // error: template-parameter redeclared
— end example]

```

- 7 In the definition of a member of a class template that appears outside of the class template definition, the name of a member of the class template hides the name of a *template-parameter* of any enclosing class templates (but not a *template-parameter* of the member if the member is a class or function template). [Example:

```

template<class T> struct A {
    struct B { /* ... */ };
    typedef void C;
    void f();
    template<class U> void g(U);
};

template<class B> void A<B>::f() {
    B b;                                // A's B, not the template parameter
}

template<class B> template<class C> void A<B>::g(C) {
    B b;                                // A's B, not the template parameter
    C c;                                // the template parameter C, not A's C
}
— end example]

```

- 8 In the definition of a member of a class template that appears outside of the namespace containing the class template definition, the name of a *template-parameter* hides the name of a member of this namespace. [Example:

```

namespace N {
    class C {};
    template<class T> class B {
        void f(T);
    };
}

```

```
template<class C> void N::B<C>::f(C) {
    C b;           // C is the template parameter, not N::C
}
```

— end example]

- <sup>9</sup> In the definition of a class template or in the definition of a member of such a template that appears outside of the template definition, for each non-dependent base class (??), if the name of the base class or the name of a member of the base class is the same as the name of a *template-parameter*, the base class name or member name hides the *template-parameter* name (??). [Example:

```
struct A {
    struct B { /* ... */ };
    int a;
    int Y;
};

template<class B, class a> struct X : A {
    B b;           // A's B
    a b;           // error: A's a isn't a type name
};

— end example]
```

## 17.7.2 Dependent names

[temp.dep]

- <sup>1</sup> Inside a template, some constructs have semantics which may differ from one instantiation to another. Such a construct *depends* on the template parameters. In particular, types and expressions may depend on the type and/or value of template parameters (as determined by the template arguments) and this determines the context for name lookup for certain names. An expression may be *type-dependent* (that is, its type may depend on a template parameter) or *value-dependent* (that is, its value when evaluated as a constant expression (??) may depend on a template parameter) as described in this subclause. In an expression of the form:

*postfix-expression* ( *expression-list<sub>opt</sub>* )

where the *postfix-expression* is an *unqualified-id*, the *unqualified-id* denotes a *dependent name* if

- (1.1) — any of the expressions in the *expression-list* is a pack expansion (??),
- (1.2) — any of the expressions or *braced-init-lists* in the *expression-list* is type-dependent (??), or
- (1.3) — the *unqualified-id* is a *template-id* in which any of the template arguments depends on a template parameter.

If an operand of an operator is a type-dependent expression, the operator also denotes a dependent name. Such names are unbound and are looked up at the point of the template instantiation (??) in both the context of the template definition and the context of the point of instantiation.

- <sup>2</sup> [Example:

```
template<class T> struct X : B<T> {
    typename T::A* pa;
    void f(B<T>* pb) {
        static int i = B<T>::i;
        pb->j++;
    }
};
```

```

    }
};
```

the base class name `B<T>`, the type name `T::A`, the names `B<T>>::i` and `pb->j` explicitly depend on the *template-parameter*. — end example]

- 3 In the definition of a class or class template, the scope of a dependent base class (??) is not examined during unqualified name lookup either at the point of definition of the class template or member or during an instantiation of the class template or member. [Example:

```

typedef double A;
template<class T> class B {
    typedef int A;
};
template<class T> struct X : B<T> {
    A a;           // a has type double
};
```

The type name `A` in the definition of `X<T>` binds to the `typedef` name defined in the global namespace scope, not to the `typedef` name defined in the base class `B<T>`. — end example] [Example:

```

struct A {
    struct B { /* ... */ };
    int a;
    int Y;
};

int a;

template<class T> struct Y : T {
    struct B { /* ... */ };
    B b;           // The B defined in Y
    void f(int i) { a = i; } // ::a
    Y* p;         // Y<T>
};

Y<A> ya;
```

The members `A::B`, `A::a`, and `A::Y` of the template argument `A` do not affect the binding of names in `Y<A>`. — end example]

### 17.7.2.1 Dependent types

[temp.dep.type]

- <sup>1</sup> A name refers to the *current instantiation* if it is

- (1.1) — in the definition of a class template, a nested class of a class template, a member of a class template, or a member of a nested class of a class template, the injected-class-name (??) of the class template or nested class,
- (1.2) — in the definition of a primary class template or a member of a primary class template, the name of the class template followed by the template argument list of the primary template (as described below) enclosed in `<>` (or an equivalent template alias specialization),
- (1.3) — in the definition of a nested class of a class template, the name of the nested class referenced as a member of the current instantiation, or

- (1.4) — in the definition of a partial specialization or a member of a partial specialization, the name of the class template followed by the template argument list of the partial specialization enclosed in <> (or an equivalent template alias specialization). If the *n*th template parameter is a parameter pack, the *n*th template argument is a pack expansion (??) whose pattern is the name of the parameter pack.
- 2 The template argument list of a primary template is a template argument list in which the *n*th template argument has the value of the *n*th template parameter of the class template. If the *n*th template parameter is a template parameter pack (??), the *n*th template argument is a pack expansion (??) whose pattern is the name of the template parameter pack.
  - 3 A template argument that is equivalent to a template parameter can be used in place of that template parameter in a reference to the current instantiation. For a template *type-parameter*, a template argument is equivalent to a template parameter if it denotes the same type. For a non-type template parameter, a template argument is equivalent to a template parameter if it is an *identifier* that names a variable that is equivalent to the template parameter. A variable is equivalent to a template parameter if
    - (3.1) — it has the same type as the template parameter (ignoring cv-qualification) and
    - (3.2) — its initializer consists of a single *identifier* that names the template parameter or, recursively, such a variable.

[Note: Using a parenthesized variable name breaks the equivalence. — end note] [Example:

```
template <class T> class A {
    A* p1;                                // A is the current instantiation
    A<T*>* p2;                            // A<T> is the current instantiation
    A<T*> p3;                            // A<T*> is not the current instantiation
    ::A<T*>* p4;                            // ::A<T> is the current instantiation

    class B {
        B* p1;                                // B is the current instantiation
        A<T>::B* p2;                            // A<T>::B is the current instantiation
        typename A<T*>::B* p3;                // A<T*>::B is not the current instantiation
    };
};

template <class T> class A<T*> {
    A<T*>* p1;                            // A<T*> is the current instantiation
    A<T*>* p2;                            // A<T> is not the current instantiation
};

template <class T1, class T2, int I> struct B {
    B<T1, T2, I>* b1;                  // refers to the current instantiation
    B<T2, T1, I>* b2;                  // not the current instantiation
    typedef T1 my_T1;
    static const int my_I = I;
    static const int my_I2 = I+0;
    static const int my_I3 = my_I;
    static const long my_I4 = I;
    static const int my_I5 = (I);
    B<my_T1, T2, my_I>* b3;            // refers to the current instantiation
    B<my_T1, T2, my_I2>* b4;            // not the current instantiation
    B<my_T1, T2, my_I3>* b5;            // refers to the current instantiation
};
```

```
B<my_T1, T2, my_I4>* b6;           // not the current instantiation
B<my_T1, T2, my_I5>* b7;           // not the current instantiation
};

— end example]
```

- <sup>4</sup> A *dependent base class* is a base class that is a dependent type and is not the current instantiation. [ *Note:* A base class can be the current instantiation in the case of a nested class naming an enclosing class as a base. [ *Example:*

```
template<class T> struct A {
    typedef int M;
    struct B {
        typedef void M;
        struct C;
    };
};

template<class T> struct A<T>::B::C : A<T> {
    M m;                                // OK, A<T>::M
};

— end example] — end note]
```

- <sup>5</sup> A name is a *member of the current instantiation* if it is

- (5.1) — An unqualified name that, when looked up, refers to at least one member of a class that is the current instantiation or a non-dependent base class thereof. [ *Note:* This can only occur when looking up a name in a scope enclosed by the definition of a class template. — end note]
- (5.2) — A *qualified-id* in which the *nested-name-specifier* refers to the current instantiation and that, when looked up, refers to at least one member of a class that is the current instantiation or a non-dependent base class thereof. [ *Note:* If no such member is found, and the current instantiation has any dependent base classes, then the *qualified-id* is a member of an unknown specialization; see below. — end note]
- (5.3) — An *id-expression* denoting the member in a class member access expression (??) for which the type of the object expression is the current instantiation, and the *id-expression*, when looked up (??), refers to at least one member of a class that is the current instantiation or a non-dependent base class thereof. [ *Note:* If no such member is found, and the current instantiation has any dependent base classes, then the *id-expression* is a member of an unknown specialization; see below. — end note]

[ *Example:*

```
template <class T> class A {
    static const int i = 5;
    int n1[i];                          // i refers to a member of the current instantiation
    int n2[A::i];                      // A::i refers to a member of the current instantiation
    int n3[A<T>::i];                  // A<T>::i refers to a member of the current instantiation
    int f();
};

template <class T> int A<T>::f() {
    return i;                           // i refers to a member of the current instantiation
}
```

— end example]

A name is a *dependent member of the current instantiation* if it is a member of the current instantiation that, when looked up, refers to at least one member of a class that is the current instantiation.

<sup>6</sup> A name is a *member of an unknown specialization* if it is

- (6.1) — A *qualified-id* in which the *nested-name-specifier* names a dependent type that is not the current instantiation.
- (6.2) — A *qualified-id* in which the *nested-name-specifier* refers to the current instantiation, the current instantiation has at least one dependent base class, and name lookup of the *qualified-id* does not find any member of a class that is the current instantiation or a non-dependent base class thereof.
- (6.3) — An *id-expression* denoting the member in a class member access expression (??) in which either
  - (6.3.1) — the type of the object expression is the current instantiation, the current instantiation has at least one dependent base class, and name lookup of the *id-expression* does not find a member of a class that is the current instantiation or a non-dependent base class thereof; or
  - (6.3.2) — the type of the object expression is dependent and is not the current instantiation.

<sup>7</sup> If a *qualified-id* in which the *nested-name-specifier* refers to the current instantiation is not a member of the current instantiation or a member of an unknown specialization, the program is ill-formed even if the template containing the *qualified-id* is not instantiated; no diagnostic required. Similarly, if the *id-expression* in a class member access expression for which the type of the object expression is the current instantiation does not refer to a member of the current instantiation or a member of an unknown specialization, the program is ill-formed even if the template containing the member access expression is not instantiated; no diagnostic required. [Example:

```
template<class T> class A {
    typedef int type;
    void f() {
        A<T>::type i;           // OK: refers to a member of the current instantiation
        typename A<T>::other j; // error: neither a member of the current instantiation nor
                               // a member of an unknown specialization
    }
};
```

— end example]

<sup>8</sup> If, for a given set of template arguments, a specialization of a template is instantiated that refers to a member of the current instantiation with a *qualified-id* or class member access expression, the name in the *qualified-id* or class member access expression is looked up in the template instantiation context. If the result of this lookup differs from the result of name lookup in the template definition context, name lookup is ambiguous. [Example:

```
struct A {
    int m;
};

struct B {
    int m;
};
```

```

template<typename T>
struct C : A, T {
    int f() { return this->m; }      // finds A::m in the template definition context
    int g() { return m; }            // finds A::m in the template definition context
};

template int C<B>::f();           // error: finds both A::m and B::m
template int C<B>::g();           // OK: transformation to class member access syntax
                                  // does not occur in the template definition context; see ??

— end example]

```

<sup>9</sup> A type is dependent if it is

- (9.1) — a template parameter,
- (9.2) — a member of an unknown specialization,
- (9.3) — a nested class or enumeration that is a dependent member of the current instantiation,
- (9.4) — a cv-qualified type where the cv-unqualified type is dependent,
- (9.5) — a compound type constructed from any dependent type,
- (9.6) — an array type whose element type is dependent or whose bound (if any) is value-dependent,
- (9.7) — a function type whose exception specification is value-dependent,
- (9.8) — a *simple-template-id* in which either the template name is a template parameter or any of the template arguments is a dependent type or an expression that is type-dependent or value-dependent or is a pack expansion [ *Note*: This includes an injected-class-name (??) of a class template used without a *template-argument-list*. — end note ], or
- (9.9) — denoted by `decltype(expression)`, where *expression* is type-dependent (??).

<sup>10</sup> [ *Note*: Because `typedefs` do not introduce new types, but instead simply refer to other types, a name that refers to a `typedef` that is a member of the current instantiation is dependent only if the type referred to is dependent. — end note ]

### 17.7.2.2 Type-dependent expressions

[temp.dep.expr]

- <sup>1</sup> Except as described below, an expression is type-dependent if any subexpression is type-dependent.
- <sup>2</sup> `this` is type-dependent if the class type of the enclosing member function is dependent (??).
- <sup>3</sup> An *id-expression* is type-dependent if it contains
  - (3.1) — an *identifier* associated by name lookup with one or more declarations declared with a dependent type,
  - (3.2) — an *identifier* associated by name lookup with a non-type *template-parameter* declared with a type that contains a placeholder type (??),
  - (3.3) — an *identifier* associated by name lookup with one or more declarations of member functions of the current instantiation declared with a return type that contains a placeholder type,
  - (3.4) — an *identifier* associated by name lookup with a structured binding declaration (??) whose *brace-or-equal-initializer* is type-dependent,
  - (3.5) — the *identifier* `__func__` (??), where any enclosing function is a template, a member of a class template, or a generic lambda,
  - (3.6) — a *template-id* that is dependent,

- (3.7) — a *conversion-function-id* that specifies a dependent type, or
- (3.8) — a *nested-name-specifier* or a *qualified-id* that names a member of an unknown specialization; or if it names a dependent member of the current instantiation that is a static data member of type “array of unknown bound of T” for some T (??). Expressions of the following forms are type-dependent only if the type specified by the *type-id*, *simple-type-specifier* or *new-type-id* is dependent, even if any subexpression is type-dependent:

```
simple-type-specifier ( expression-listopt )
::opt new new-placementopt new-type-id new-initializeropt
::opt new new-placementopt ( type-id ) new-initializeropt
dynamic_cast < type-id > ( expression )
static_cast < type-id > ( expression )
const_cast < type-id > ( expression )
reinterpret_cast < type-id > ( expression )
( type-id ) cast-expression
```

- <sup>4</sup> Expressions of the following forms are never type-dependent (because the type of the expression cannot be dependent):

```
literal
postfix-expression . pseudo-destructor-name
postfix-expression -> pseudo-destructor-name
sizeof unary-expression
sizeof ( type-id )
sizeof ... ( identifier )
alignof ( type-id )
typeid ( expression )
typeid ( type-id )
::opt delete cast-expression
::opt delete [ ] cast-expression
throw assignment-expressionopt
noexcept ( expression )
```

[ *Note*: For the standard library macro *offsetof*, see ???. — *end note* ]

- <sup>5</sup> A class member access expression (??) is type-dependent if the expression refers to a member of the current instantiation and the type of the referenced member is dependent, or the class member access expression refers to a member of an unknown specialization. [ *Note*: In an expression of the form *x.y* or *xp->y* the type of the expression is usually the type of the member *y* of the class of *x* (or the class pointed to by *xp*). However, if *x* or *xp* refers to a dependent type that is not the current instantiation, the type of *y* is always dependent. If *x* or *xp* refers to a non-dependent type or refers to the current instantiation, the type of *y* is the type of the class member access expression. — *end note* ]

- <sup>6</sup> A *braced-init-list* is type-dependent if any element is type-dependent or is a pack expansion.

- <sup>7</sup> A *fold-expression* is type-dependent.

### 17.7.2.3 Value-dependent expressions

[temp.dep.constexpr]

- <sup>1</sup> Except as described below, an expression used in a context where a constant expression is required is value-dependent if any subexpression is value-dependent.

- <sup>2</sup> An *id-expression* is value-dependent if:

- (2.1) — it is type-dependent,

- (2.2) — it is the name of a non-type template parameter,
- (2.3) — it names a static data member that is a dependent member of the current instantiation and is not initialized in a *member-declarator*,
- (2.4) — it names a static member function that is a dependent member of the current instantiation, or
- (2.5) — it is a constant with literal type and is initialized with an expression that is value-dependent.

Expressions of the following form are value-dependent if the *unary-expression* or *expression* is type-dependent or the *type-id* is dependent:

```
sizeof unary-expression
sizeof ( type-id )
typeid ( expression )
typeid ( type-id )
alignof ( type-id )
noexcept ( expression )
```

[*Note*: For the standard library macro `offsetof`, see ???. — *end note*]

- 3 Expressions of the following form are value-dependent if either the *type-id* or *simple-type-specifier* is dependent or the *expression* or *cast-expression* is value-dependent:

```
simple-type-specifier ( expression-listopt )
static_cast < type-id > ( expression )
const_cast < type-id > ( expression )
reinterpret_cast < type-id > ( expression )
( type-id ) cast-expression
```

- 4 Expressions of the following form are value-dependent:

```
sizeof ... ( identifier )
fold-expression
```

- 5 An expression of the form `&qualified-id` where the *qualified-id* names a dependent member of the current instantiation is value-dependent. An expression of the form `&cast-expression` is also value-dependent if evaluating *cast-expression* as a core constant expression (??) succeeds and the result of the evaluation refers to a templated entity that is an object with static or thread storage duration or a member function.

#### 17.7.2.4 Dependent template arguments

[temp.dep.temp]

- <sup>1</sup> A type *template-argument* is dependent if the type it specifies is dependent.
- <sup>2</sup> A non-type *template-argument* is dependent if its type is dependent or the constant expression it specifies is value-dependent.
- <sup>3</sup> Furthermore, a non-type *template-argument* is dependent if the corresponding non-type *template-parameter* is of reference or pointer type and the *template-argument* designates or points to a member of the current instantiation or a member of a dependent type.
- <sup>4</sup> A template *template-argument* is dependent if it names a *template-parameter* or is a *qualified-id* that refers to a member of an unknown specialization.

#### 17.7.3 Non-dependent names

[temp.nondep]

- <sup>1</sup> Non-dependent names used in a template definition are found using the usual name lookup and bound at the point they are used. [*Example*:

```
void g(double);
```

```

void h();

template<class T> class Z {
public:
    void f() {
        g(1);           // calls g(double)
        h++;            // ill-formed: cannot increment function; this could be diagnosed
                        // either here or at the point of instantiation
    }
};

void g(int);           // not in scope at the point of the template definition, not considered for the call g(1)

— end example]

```

#### 17.7.4 Dependent name resolution

[temp.dep.res]

- <sup>1</sup> In resolving dependent names, names from the following sources are considered:

- (1.1) — Declarations that are visible at the point of definition of the template.
- (1.2) — Declarations from namespaces associated with the types of the function arguments both from the instantiation context (??) and from the definition context.

##### 17.7.4.1 Point of instantiation

[temp.point]

- 1 For a function template specialization, a member function template specialization, or a specialization for a member function or static data member of a class template, if the specialization is implicitly instantiated because it is referenced from within another template specialization and the context from which it is referenced depends on a template parameter, the point of instantiation of the specialization is the point of instantiation of the enclosing specialization. Otherwise, the point of instantiation for such a specialization immediately follows the namespace scope declaration or definition that refers to the specialization.
- 2 If a function template or member function of a class template is called in a way which uses the definition of a default argument of that function template or member function, the point of instantiation of the default argument is the point of instantiation of the function template or member function specialization.
- 3 For a *noexcept-specifier* of a function template specialization or specialization of a member function of a class template, if the *noexcept-specifier* is implicitly instantiated because it is needed by another template specialization and the context that requires it depends on a template parameter, the point of instantiation of the *noexcept-specifier* is the point of instantiation of the specialization that requires it. Otherwise, the point of instantiation for such a *noexcept-specifier* immediately follows the namespace scope declaration or definition that requires the *noexcept-specifier*.
- 4 For a class template specialization, a class member template specialization, or a specialization for a class member of a class template, if the specialization is implicitly instantiated because it is referenced from within another template specialization, if the context from which the specialization is referenced depends on a template parameter, and if the specialization is not instantiated previous to the instantiation of the enclosing template, the point of instantiation is immediately before the point of instantiation of the enclosing template. Otherwise, the point of instantiation for such a specialization immediately precedes the namespace scope declaration or definition that refers to the specialization.
- 5 If a virtual function is implicitly instantiated, its point of instantiation is immediately following the point of instantiation of its enclosing class template specialization.

- <sup>6</sup> An explicit instantiation definition is an instantiation point for the specialization or specializations specified by the explicit instantiation.
- <sup>7</sup> The instantiation context of an expression that depends on the template arguments is the set of declarations with external linkage declared prior to the point of instantiation of the template specialization in the same translation unit.
- <sup>8</sup> A specialization for a function template, a member function template, or of a member function or static data member of a class template may have multiple points of instantiations within a translation unit, and in addition to the points of instantiation described above, for any such specialization that has a point of instantiation within the translation unit, the end of the translation unit is also considered a point of instantiation. A specialization for a class template has at most one point of instantiation within a translation unit. A specialization for any template may have points of instantiation in multiple translation units. If two different points of instantiation give a template specialization different meanings according to the one-definition rule (??), the program is ill-formed, no diagnostic required.

#### 17.7.4.2 Candidate functions

[temp.dep.candidate]

- <sup>1</sup> For a function call where the *postfix-expression* is a dependent name, the candidate functions are found using the usual lookup rules (??, ??) except that:
  - (1.1) — For the part of the lookup using unqualified name lookup (??), only function declarations from the template definition context are found.
  - (1.2) — For the part of the lookup using associated namespaces (??), only function declarations found in either the template definition context or the template instantiation context are found.

If the call would be ill-formed or would find a better match had the lookup within the associated namespaces considered all the function declarations with external linkage introduced in those namespaces in all translation units, not just considering those declarations found in the template definition and template instantiation contexts, then the program has undefined behavior.

#### 17.7.5 Friend names declared within a class template

[temp.inject]

- <sup>1</sup> Friend classes or functions can be declared within a class template. When a template is instantiated, the names of its friends are treated as if the specialization had been explicitly declared at its point of instantiation.
- <sup>2</sup> As with non-template classes, the names of namespace-scope friend functions of a class template specialization are not visible during an ordinary lookup unless explicitly declared at namespace scope (??). Such names may be found under the rules for associated classes (??).<sup>143</sup> [Example:

```
template<typename T> struct number {
    number(int);
    friend number gcd(number x, number y) { return 0; };
};

void g() {
    number<double> a(3), b(4);
    a = gcd(a,b);      // finds gcd because number<double> is an associated class,
                       // making gcd visible in its namespace (global scope)
    b = gcd(3,4);     // ill-formed; gcd is not visible
}
```

---

<sup>143</sup>) Friend declarations do not introduce new names into any scope, either when the template is declared or when it is instantiated.

— end example ]

## 17.8 Template instantiation and specialization

[temp.spec]

- <sup>1</sup> The act of instantiating a function, a class, a member of a class template or a member template is referred to as *template instantiation*.
- <sup>2</sup> A function instantiated from a function template is called an instantiated function. A class instantiated from a class template is called an instantiated class. A member function, a member class, a member enumeration, or a static data member of a class template instantiated from the member definition of the class template is called, respectively, an instantiated member function, member class, member enumeration, or static data member. A member function instantiated from a member function template is called an instantiated member function. A member class instantiated from a member class template is called an instantiated member class.
- <sup>3</sup> An explicit specialization may be declared for a function template, a class template, a member of a class template or a member template. An explicit specialization declaration is introduced by `template<>`. In an explicit specialization declaration for a class template, a member of a class template or a class member template, the name of the class that is explicitly specialized shall be a *simple-template-id*. In the explicit specialization declaration for a function template or a member function template, the name of the function or member function explicitly specialized may be a *template-id*. [ Example:

```
template<class T = int> struct A {
    static int x;
};

template<class U> void g(U) { }

template<> struct A<double> { };           // specialize for T == double
template<> struct A<> { };                 // specialize for T == int
template<> void g(char) { }                  // specialize for U == char
                                                // U is deduced from the parameter type
template<> void g<int>(int) { }             // specialize for U == int
template<> int A<char>::x = 0;              // specialize for T == char

template<class T = int> struct B {
    static int x;
};

template<> int B<>::x = 1;                  // specialize for T == int
```

— end example ]

- 4 An instantiated template specialization can be either implicitly instantiated (??) for a given argument list or be explicitly instantiated (??). A specialization is a class, function, or class member that is either instantiated or explicitly specialized (??).
- 5 For a given template and a given set of *template-arguments*,

- (5.1) — an explicit instantiation definition shall appear at most once in a program,
- (5.2) — an explicit specialization shall be defined at most once in a program (according to ??), and
- (5.3) — both an explicit instantiation and a declaration of an explicit specialization shall not appear in a program unless the explicit instantiation follows a declaration of the explicit specialization.

An implementation is not required to diagnose a violation of this rule.

- <sup>6</sup> The usual access checking rules do not apply to names in a declaration of an explicit instantiation or explicit specialization, with the exception of names appearing in a function body, default argument, base-clause, member-specification, enumerator-list, or static data member or variable template initializer. [Note: In particular, the template arguments and names used in the function declarator (including parameter types, return types and exception specifications) may be private types or objects that would normally not be accessible. —end note]
- <sup>7</sup> Each class template specialization instantiated from a template has its own copy of any static members. [Example:

```
template<class T> class X {
    static T s;
};

template<class T> T X<T>::s = 0;
X<int> aa;
X<char*> bb;
```

X<int> has a static member s of type int and X<char\*> has a static member s of type char\*. —end example]

- <sup>8</sup> If a function declaration acquired its function type through a dependent type (??) without using the syntactic form of a function declarator, the program is ill-formed. [Example:

```
template<class T> struct A {
    static T t;
};

typedef int function();
A<function> a;           // ill-formed: would declare A<function>::t as a static member function
—end example]
```

### 17.8.1 Implicit instantiation

[temp.inst]

- <sup>1</sup> Unless a class template specialization has been explicitly instantiated (??) or explicitly specialized (??), the class template specialization is implicitly instantiated when the specialization is referenced in a context that requires a completely-defined object type or when the completeness of the class type affects the semantics of the program. [Note: In particular, if the semantics of an expression depend on the member or base class lists of a class template specialization, the class template specialization is implicitly generated. For instance, deleting a pointer to class type depends on whether or not the class declares a destructor, and a conversion between pointers to class type depends on the inheritance relationship between the two classes involved. —end note] [Example:

```
template<class T> class B { /* ... */ };
template<class T> class D : public B<T> { /* ... */ };

void f(void*);
void f(B<int>*);

void g(D<int>* p, D<char>* pp, D<double>* ppp) {
    f(p);           // instantiation of D<int> required: call f(B<int>*)
    B<char>* q = pp; // instantiation of D<char> required: convert D<char>* to B<char>*
    delete ppp;     // instantiation of D<double> required
}
```

— *end example*] If a class template has been declared, but not defined, at the point of instantiation (??), the instantiation yields an incomplete class type (??). [ *Example*:

```
template<class T> class X;
X<char> ch;           // error: incomplete type X<char>
```

— *end example*] [ *Note*: Within a template declaration, a local class (??) or enumeration and the members of a local class are never considered to be entities that can be separately instantiated (this includes their default arguments, *noexcept-specifiers*, and non-static data member initializers, if any, but not their *partial-concept-ids* or *requires-clauses*). As a result, the dependent names are looked up, the semantic constraints are checked, and any templates used are instantiated as part of the instantiation of the entity within which the local class or enumeration is declared. — *end note*]

- 2 The implicit instantiation of a class template specialization causes the implicit instantiation of the declarations, but not of the definitions, default arguments, or *noexcept-specifiers* of the class member functions, member classes, scoped member enumerations, static data members, member templates, and friends; and it causes the implicit instantiation of the definitions of unscoped member enumerations and member anonymous unions. However, for the purpose of determining whether an instantiated redeclaration is valid according to ?? and ??, a declaration that corresponds to a definition in the template is considered to be a definition. [ *Example*:

```
template<class T, class U>
struct Outer {
    template<class X, class Y> struct Inner;
    template<class Y> struct Inner<T, Y>;           // #1a
    template<class Y> struct Inner<T, Y> { };        // #1b; OK: valid redeclaration of #1a
    template<class Y> struct Inner<U, Y> { };        // #2
};

Outer<int, int> outer;                         // error at #2
```

`Outer<int, int>::Inner<int, Y>` is redeclared at #1b. (It is not defined but noted as being associated with a definition in `Outer<T, U>`.) #2 is also a redeclaration of #1a. It is noted as associated with a definition, so it is an invalid redeclaration of the same partial specialization.

```
template<typename T> struct Friendly {
    template<typename U> friend int f(U) { return sizeof(T); }
};
Friendly<char> fc;
Friendly<float> ff;                           // ill-formed: produces second definition of f(U)

— end example]
```

- 3 Unless a member of a class template or a member template has been explicitly instantiated or explicitly specialized, the specialization of the member is implicitly instantiated when the specialization is referenced in a context that requires the member definition to exist or if the existence of the definition of the member affects the semantics of the program; in particular, the initialization (and any associated side effects) of a static data member does not occur unless the static data member is itself used in a way that requires the definition of the static data member to exist.
- 4 Unless a function template specialization has been explicitly instantiated or explicitly specialized, the function template specialization is implicitly instantiated when the specialization is referenced in a context that requires a function definition to exist or if the existence of the definition affects the semantics of the program. A function whose declaration was instantiated from a friend function definition is implicitly instantiated when

it is referenced in a context that requires a function definition to exist or if the existence of the definition affects the semantics of the program. Unless a call is to a function template explicit specialization or to a member function of an explicitly specialized class template, a default argument for a function template or a member function of a class template is implicitly instantiated when the function is called in a context that requires the value of the default argument.

<sup>5</sup> [ *Example:*

```
template<class T> struct Z {
    void f();
    void g();
};

void h() {
    Z<int> a;           // instantiation of class Z<int> required
    Z<char>* p;         // instantiation of class Z<char> not required
    Z<double>* q;       // instantiation of class Z<double> not required

    a.f();              // instantiation of Z<int>::f() required
    p->g();             // instantiation of class Z<char> required, and
                         // instantiation of Z<char>::g() required
}
```

Nothing in this example requires `class Z<double>`, `Z<int>::g()`, or `Z<char>::f()` to be implicitly instantiated. — *end example*]

- <sup>6</sup> Unless a variable template specialization has been explicitly instantiated or explicitly specialized, the variable template specialization is implicitly instantiated when it is referenced in a context that requires a variable definition to exist or if the existence of the definition affects the semantics of the program. A default template argument for a variable template is implicitly instantiated when the variable template is referenced in a context that requires the value of the default argument.
- <sup>7</sup> The existence of a definition of a variable or function is considered to affect the semantics of the program if the variable or function is needed for constant evaluation by an expression (??), even if constant evaluation of the expression is not required or if constant expression evaluation does not use the definition.

[ *Example:*

```
template<typename T> constexpr int f() { return T::value; }
template<bool B, typename T> void g(decltype(B ? f<T>() : 0));
template<bool B, typename T> void g(...);
template<bool B, typename T> void h(decltype(int{B ? f<T>() : 0}));
template<bool B, typename T> void h(...);
void x() {
    g<false, int>(0); // OK, B ? f<T>() : 0 is not potentially constant evaluated
    h<false, int>(0); // error, instantiates f<int> even though B evaluates to false and
                      // list-initialization of int from int cannot be narrowing
}
```

— *end example*]

- <sup>8</sup> If the function selected by overload resolution (??) can be determined without instantiating a class template definition, it is unspecified whether that instantiation actually takes place. [ *Example:*

```

template <class T> struct S {
    operator int();
};

void f(int);
void f(S<int>&);
void f(S<float>);

void g(S<int>& sr) {
    f(sr);           // instantiation of S<int> allowed but not required
    // instantiation of S<float> allowed but not required
}
— end example]

```

- <sup>9</sup> If a function template or a member function template specialization is used in a way that involves overload resolution, a declaration of the specialization is implicitly instantiated (??).
- <sup>10</sup> An implementation shall not implicitly instantiate a function template, a variable template, a member template, a non-virtual member function, a member class, a static data member of a class template, or a substatement of a constexpr if statement (??), unless such instantiation is required. [Note: The instantiation of a generic lambda does not require instantiation of substatements of a constexpr if statement within its *compound-statement* unless the call operator template is instantiated. — end note] It is unspecified whether or not an implementation implicitly instantiates a virtual member function of a class template if the virtual member function would not otherwise be instantiated. The use of a template specialization in a default argument shall not cause the template to be implicitly instantiated except that a class template may be instantiated where its complete type is needed to determine the correctness of the default argument. The use of a default argument in a function call causes specializations in the default argument to be implicitly instantiated.
- <sup>11</sup> Implicitly instantiated class, function, and variable template specializations are placed in the namespace where the template is defined. Implicitly instantiated specializations for members of a class template are placed in the namespace where the enclosing class template is defined. Implicitly instantiated member templates are placed in the namespace where the enclosing class or class template is defined. [Example:

```

namespace N {
    template<class T> class List {
        public:
            T* get();
    };
}

template<class K, class V> class Map {
    public:
        N::List<V> lt;
        V get(K);
    };
}

void g(Map<const char*,int>& m) {
    int i = m.get("Nicholas");
}

```

a call of `lt.get()` from `Map<const char*,int>::get()` would place `List<int>::get()` in the namespace `N` rather than in the global namespace. — end example]

- <sup>12</sup> If a function template `f` is called in a way that requires a default argument to be used, the dependent names are looked up, the semantics constraints are checked, and the instantiation of any template used in the default argument is done as if the default argument had been an initializer used in a function template specialization with the same scope, the same template parameters and the same access as that of the function template `f` used at that point, except that the scope in which a closure type is declared (??) – and therefore its associated namespaces – remain as determined from the context of the definition for the default argument. This analysis is called *default argument instantiation*. The instantiated default argument is then used as the argument of `f`.

- <sup>13</sup> Each default argument is instantiated independently. [Example:

```
template<class T> void f(T x, T y = ydef(T()), T z = zdef(T()));

class A {};

A zdef(A);

void g(A a, A b, A c) {
    f(a, b, c);           // no default argument instantiation
    f(a, b);              // default argument z = zdef(T()) instantiated
    f(a);                 // ill-formed; ydef is not declared
}
```

— end example]

- <sup>14</sup> The *noexcept-specifier* of a function template specialization is not instantiated along with the function declaration; it is instantiated when needed (??). If such an *noexcept-specifier* is needed but has not yet been instantiated, the dependent names are looked up, the semantics constraints are checked, and the instantiation of any template used in the *noexcept-specifier* is done as if it were being done as part of instantiating the declaration of the specialization at that point.

- <sup>15</sup> [Note: ?? defines the point of instantiation of a template specialization. — end note]

- <sup>16</sup> There is an implementation-defined quantity that specifies the limit on the total depth of recursive instantiations (??), which could involve more than one template. The result of an infinite recursion in instantiation is undefined. [Example:

```
template<class T> class X {
    X<T*>* p;           // OK
    X<T*> a;             // implicit generation of X<T> requires
                           // the implicit instantiation of X<T*> which requires
                           // the implicit instantiation of X<T**> which ...
};

— end example]
```

- <sup>17</sup> The *partial-concept-ids* and *requires-clause* of a template specialization or member function are not instantiated along with the specialization or function itself, even for a member function of a local class; substitution into the atomic constraints formed from them is instead performed as specified in ?? and ?? when determining whether the constraints are satisfied. [Note: The satisfaction of constraints is determined during name lookup or overload resolution (??). — end note] [Example:

```

template<typename T> concept C = sizeof(T) > 2;
template<typename T> concept D = C<T> && sizeof(T) > 4;

template<typename T> struct S {
    S() requires C<T> {}           // #1
    S() requires D<T> {}           // #2
};

S<char> s1;                      // error: no matching constructor
S<char[8]> s2;                  // OK, calls #2

```

When `S<char>` is instantiated, both constructors are part of the specialization. Their constraints are not satisfied, and they suppress the implicit declaration of a default constructor for `S<char>` (??), so there is no viable constructor for `s1`. — *end example*] [Example:

```

template<typename T> struct S1 {
    template<typename U>
    requires false
    struct Inner1;                // ill-formed, no diagnostic required
};

template<typename T> struct S2 {
    template<typename U>
    requires (sizeof(T[-(int)sizeof(T)]) > 1)
    struct Inner2;                // ill-formed, no diagnostic required
};

```

The class `S1<T>::Inner1` is ill-formed, no diagnostic required, because it has no valid specializations. `S2` is ill-formed, no diagnostic required, since no substitution into the constraints of its `Inner2` template would result in a valid expression. — *end example*]

### 17.8.2 Explicit instantiation

[**temp.explicit**]

- <sup>1</sup> A class, function, variable, or member template specialization can be explicitly instantiated from its template. A member function, member class or static data member of a class template can be explicitly instantiated from the member definition associated with its class template. An explicit instantiation of a function template, member function of a class template, or variable template shall not use the `inline` or `constexpr` specifiers.
- <sup>2</sup> The syntax for explicit instantiation is:

*explicit-instantiation:*

```
externopt template declaration
```

There are two forms of explicit instantiation: an explicit instantiation definition and an explicit instantiation declaration. An explicit instantiation declaration begins with the `extern` keyword.

- <sup>3</sup> If the explicit instantiation is for a class or member class, the *elaborated-type-specifier* in the *declaration* shall include a *simple-template-id*; otherwise, the *declaration* shall be a *simple-declaration* whose *init-declarator-list* comprises a single *init-declarator* that does not have an *initializer*. If the explicit instantiation is for a function or member function, the *unqualified-id* in the *declarator* shall be either a *template-id* or, where all template arguments can be deduced, a *template-name* or *operator-function-id*. [Note: The declaration may declare a *qualified-id*, in which case the *unqualified-id* of the *qualified-id* must be a *template-id*. — *end note*] If the explicit instantiation is for a member function, a member class or a static data member of a class template specialization, the name of the class template specialization in the *qualified-id* for the member

name shall be a *simple-template-id*. If the explicit instantiation is for a variable template specialization, the *unqualified-id* in the *declarator* shall be a *simple-template-id*. An explicit instantiation shall appear in an enclosing namespace of its template. If the name declared in the explicit instantiation is an unqualified name, the explicit instantiation shall appear in the namespace where its template is declared or, if that namespace is inline (??), any namespace from its enclosing namespace set. [ *Note*: Regarding qualified names in declarators, see ???. — *end note*] [ *Example*:

```
template<class T> class Array { void mf(); };
template class Array<char>;
template void Array<int>::mf();

template<class T> void sort(Array<T>& v) { /* ... */ }
template void sort(Array<char>&);           // argument is deduced here

namespace N {
    template<class T> void f(T&) { }
}
template void N::f<int>(int&);

— end example ]
```

- <sup>4</sup> A declaration of a function template, a variable template, a member function or static data member of a class template, or a member function template of a class or class template shall precede an explicit instantiation of that entity. A definition of a class template, a member class of a class template, or a member class template of a class or class template shall precede an explicit instantiation of that entity unless the explicit instantiation is preceded by an explicit specialization of the entity with the same template arguments. If the *declaration* of the explicit instantiation names an implicitly-declared special member function (??), the program is ill-formed.
- <sup>5</sup> The *declaration* in an *explicit-instantiation* and the *declaration* produced by the corresponding substitution into the templated function, variable, or class are two declarations of the same entity. [ *Note*: These declarations are required to have matching types as specified in ??, except as specified in ???. [ *Example*:

```
template<typename T> T var = {};
template float var<float>;           // OK, instantiated variable has type float
template int var<int[16]>[];          // OK, absence of major array bound is permitted
template int *var<int>;               // error: instantiated variable has type int

template<typename T> auto av = T();
template int av<int>;                // OK, variable with type int can be redeclared with type auto

template<typename T> auto f() {}
template void f<int>();              // error: function with deduced return type
                                         // redeclared with non-deduced return type (??)
```

— *end example*] — *end note*] Despite its syntactic form, the *declaration* in an *explicit-instantiation* for a variable is not itself a definition and does not conflict with the definition instantiated by an explicit instantiation definition for that variable.

- <sup>6</sup> For a given set of template arguments, if an explicit instantiation of a template appears after a declaration of an explicit specialization for that template, the explicit instantiation has no effect. Otherwise, for an explicit instantiation definition the definition of a function template, a variable template, a member function template,

or a member function or static data member of a class template shall be present in every translation unit in which it is explicitly instantiated.

- 7 An explicit instantiation of a class, function template, or variable template specialization is placed in the namespace in which the template is defined. An explicit instantiation for a member of a class template is placed in the namespace where the enclosing class template is defined. An explicit instantiation for a member template is placed in the namespace where the enclosing class or class template is defined. [ *Example*:

```
namespace N {
    template<class T> class Y { void mf() { } };
}

template class Y<int>;           // error: class template Y not visible in the global namespace

using N::Y;
template class Y<int>;           // error: explicit instantiation outside of the namespace of the template

template class N::Y<char*>;       // OK: explicit instantiation in namespace N
template void N::Y<double>::mf();   // OK: explicit instantiation in namespace N

— end example ]
```

- 8 A trailing *template-argument* can be left unspecified in an explicit instantiation of a function template specialization or of a member function template specialization provided it can be deduced from the type of a function parameter (??). [ *Example*:

```
template<class T> class Array { /* ... */ };
template<class T> void sort(Array<T>& v) { /* ... */ }

// instantiate sort(Array<int>&) – template-argument deduced
template void sort<>(Array<int>&);

— end example ]
```

- 9 [ *Note*: An explicit instantiation of a constrained template shall satisfy that template's associated constraints (??). The satisfaction of constraints is determined when forming the template name of an explicit instantiation in which all template arguments are specified (??), or, for explicit instantiations of function templates, during template argument deduction (??) when one or more trailing template arguments are left unspecified. — *end note* ]

- 10 An explicit instantiation that names a class template specialization is also an explicit instantiation of the same kind (declaration or definition) of each of its members (not including members inherited from base classes and members that are templates) that has not been previously explicitly specialized in the translation unit containing the explicit instantiation, provided that the associated constraints, if any, of that member are satisfied by the template arguments of the explicit instantiation (??, ??), except as described below. [ *Note*: In addition, it will typically be an explicit instantiation of certain implementation-dependent data about the class. — *end note* ]

- 11 An explicit instantiation definition that names a class template specialization explicitly instantiates the class template specialization and is an explicit instantiation definition of only those members that have been defined at the point of instantiation.

- 12 Except for inline functions and variables, declarations with types deduced from their initializer or return value (??), **const** variables of literal types, variables of reference types, and class template specializations,

explicit instantiation declarations have the effect of suppressing the implicit instantiation of the definition of the entity to which they refer. [ *Note:* The intent is that an inline function that is the subject of an explicit instantiation declaration will still be implicitly instantiated when odr-used (??) so that the body can be considered for inlining, but that no out-of-line copy of the inline function would be generated in the translation unit. — *end note* ]

- 13 If an entity is the subject of both an explicit instantiation declaration and an explicit instantiation definition in the same translation unit, the definition shall follow the declaration. An entity that is the subject of an explicit instantiation declaration and that is also used in a way that would otherwise cause an implicit instantiation (??) in the translation unit shall be the subject of an explicit instantiation definition somewhere in the program; otherwise the program is ill-formed, no diagnostic required. [ *Note:* This rule does apply to inline functions even though an explicit instantiation declaration of such an entity has no other normative effect. This is needed to ensure that if the address of an inline function is taken in a translation unit in which the implementation chose to suppress the out-of-line body, another translation unit will supply the body. — *end note* ] An explicit instantiation declaration shall not name a specialization of a template with internal linkage.
- 14 An explicit instantiation does not constitute a use of a default argument, so default argument instantiation is not done. [ *Example:*

```
char* p = 0;
template<class T> T g(T x = &p) { return x; }
template int g<int>(int);           // OK even though &p isn't an int.

— end example ]
```

### 17.8.3 Explicit specialization

[temp.expl.spec]

- <sup>1</sup> An explicit specialization of any of the following:

- (1.1) — function template
- (1.2) — class template
- (1.3) — variable template
- (1.4) — member function of a class template
- (1.5) — static data member of a class template
- (1.6) — member class of a class template
- (1.7) — member enumeration of a class template
- (1.8) — member class template of a class or class template
- (1.9) — member function template of a class or class template

can be declared by a declaration introduced by `template<>`; that is:

*explicit-specialization:*  
`template < > declaration`

[ *Example:*

```
template<class T> class stream;

template<> class stream<char> { /* ... */ };
```

```
template<class T> class Array { /* ... */ };
template<class T> void sort(Array<T>& v) { /* ... */ }

template<> void sort<char*>(Array<char*>&);
```

Given these declarations, `stream<char>` will be used as the definition of streams of `chars`; other streams will be handled by class template specializations instantiated from the class template. Similarly, `sort<char*>` will be used as the sort function for arguments of type `Array<char*>`; other `Array` types will be sorted by functions generated from the template. — *end example*]

- 2 An explicit specialization may be declared in any scope in which the corresponding primary template may be defined (??, ??, ??).
- 3 A declaration of a function template, class template, or variable template being explicitly specialized shall precede the declaration of the explicit specialization. [ *Note*: A declaration, but not a definition of the template is required. — *end note* ] The definition of a class or class template shall precede the declaration of an explicit specialization for a member template of the class or class template. [ *Example*:

```
template<> class X<int> { /* ... */ }; // error: X not a template
```

```
template<class T> class X;

template<> class X<char*> { /* ... */ }; // OK: X is a template
```

— *end example*]

- 4 A member function, a member function template, a member class, a member enumeration, a member class template, a static data member, or a static data member template of a class template may be explicitly specialized for a class specialization that is implicitly instantiated; in this case, the definition of the class template shall precede the explicit specialization for the member of the class template. If such an explicit specialization for the member of a class template names an implicitly-declared special member function (??), the program is ill-formed.
- 5 A member of an explicitly specialized class is not implicitly instantiated from the member declaration of the class template; instead, the member of the class template specialization shall itself be explicitly defined if its definition is required. In this case, the definition of the class template explicit specialization shall be in scope at the point at which the member is defined. The definition of an explicitly specialized class is unrelated to the definition of a generated specialization. That is, its members need not have the same names, types, etc. as the members of a generated specialization. Members of an explicitly specialized class template are defined in the same manner as members of normal classes, and not using the `template<>` syntax. The same is true when defining a member of an explicitly specialized member class. However, `template<>` is used in defining a member of an explicitly specialized member class template that is specialized as a class template. [ *Example*:

```
template<class T> struct A {
    struct B { };
    template<class U> struct C { };
};

template<> struct A<int> {
    void f(int);
};
```

```

void h() {
    A<int> a;
    a.f(16);           // A<int>::f must be defined somewhere
}

// template<> not used for a member of an explicitly specialized class template
void A<int>::f(int) { /* ... */ }

template<> struct A<char>::B {
    void f();
};

// template<> also not used when defining a member of an explicitly specialized member class
void A<char>::B::f() { /* ... */ }

template<> template<class U> struct A<char>::C {
    void f();
};

// template<> is used when defining a member of an explicitly specialized member class template
// specialized as a class template
template<>
template<class U> void A<char>::C<U>::f() { /* ... */ }

template<> struct A<short>::B {
    void f();
};

template<> void A<short>::B::f() { /* ... */ }           // error: template<> not permitted

template<> template<class U> struct A<short>::C {
    void f();
};

template<class U> void A<short>::C<U>::f() { /* ... */ } // error: template<> required
— end example ]

```

<sup>6</sup> If a template, a member template or a member of a class template is explicitly specialized then that specialization shall be declared before the first use of that specialization that would cause an implicit instantiation to take place, in every translation unit in which such a use occurs; no diagnostic is required. If the program does not provide a definition for an explicit specialization and either the specialization is used in a way that would cause an implicit instantiation to take place or the member is a virtual member function, the program is ill-formed, no diagnostic required. An implicit instantiation is never generated for an explicit specialization that is declared but not defined. [ *Example:* ]

```

class String { };
template<class T> class Array { /* ... */ };
template<class T> void sort(Array<T>& v) { /* ... */ }

void f(Array<String>& v) {
    sort(v);           // use primary template sort(Array<T>&), T is String
}

template<> void sort<String>(Array<String>& v);      // error: specialization after use of primary template

```

```

template<> void sort<>(Array<char*>& v);           // OK: sort<char*> not yet used
template<class T> struct A {
    enum E : T;
    enum class S : T;
};

template<> enum A<int>::E : int { eint };           // OK
template<> enum class A<int>::S : int { sint };     // OK
template<class T> enum A<T>::E : T { eT };
template<class T> enum class A<T>::S : T { sT };

template<> enum A<char>::E : char { echar };        // ill-formed, A<char>::E was instantiated
                                                       // when A<char> was instantiated
template<> enum class A<char>::S : char { schar };   // OK

— end example ]

```

- <sup>7</sup> The placement of explicit specialization declarations for function templates, class templates, variable templates, member functions of class templates, static data members of class templates, member classes of class templates, member enumerations of class templates, member class templates of class templates, member function templates of class templates, static data member templates of class templates, member functions of member templates of class templates, member functions of member templates of non-template classes, static data member templates of non-template classes, member function templates of member classes of class templates, etc., and the placement of partial specialization declarations of class templates, variable templates, member class templates of non-template classes, static data member templates of non-template classes, member class templates of class templates, etc., can affect whether a program is well-formed according to the relative positioning of the explicit specialization declarations and their points of instantiation in the translation unit as specified above and below. When writing a specialization, be careful about its location; or to make it compile will be such a trial as to kindle its self-immolation.

- <sup>8</sup> A template explicit specialization is in the scope of the namespace in which the template was defined.  
[ Example:

```

namespace N {
    template<class T> class X { /* ... */ };
    template<class T> class Y { /* ... */ };

    template<> class X<int> { /* ... */ };           // OK: specialization in same namespace
    template<> class Y<double>;                      // forward-declare intent to specialize for double
}

template<> class N::Y<double> { /* ... */ };       // OK: specialization in enclosing namespace
template<> class N::Y<short> { /* ... */ };        // OK: specialization in enclosing namespace

— end example ]

```

- <sup>9</sup> A *simple-template-id* that names a class template explicit specialization that has been declared but not defined can be used exactly like the names of other incompletely-defined classes (??). [ Example:

```

template<class T> class X;                         // X is a class template
template<> class X<int>;

X<int>* p;                                       // OK: pointer to declared class X<int>
X<int> x;                                         // error: object of incomplete class X<int>

```

— end example ]

- 10 A trailing *template-argument* can be left unspecified in the *template-id* naming an explicit function template specialization provided it can be deduced from the function argument type. [ *Example*:

```
template<class T> class Array { /* ... */ };
template<class T> void sort(Array<T>& v);

// explicit specialization for sort(Array<int>&)
// with deduced template-argument of type int
template<> void sort(Array<int>&);
```

— end example ]

- 11 [ *Note*: An explicit specialization of a constrained template shall satisfy that template's associated constraints (??). The satisfaction of constraints is determined when forming the template name of an explicit specialization in which all template arguments are specified (??), or, for explicit specializations of function templates, during template argument deduction (??) when one or more trailing template arguments are left unspecified.

— end note ]

- 12 A function with the same name as a template and a type that exactly matches that of a template specialization is not an explicit specialization (??).

- 13 An explicit specialization of a function or variable template is inline only if it is declared with the `inline` specifier or defined as deleted, and independently of whether its function or variable template is inline. [ *Example*:

```
template<class T> void f(T) { /* ... */ }
template<class T> inline T g(T) { /* ... */ }

template<> inline void f<>(int) { /* ... */ }    // OK: inline
template<> int g<>(int) { /* ... */ }           // OK: not inline
```

— end example ]

- 14 An explicit specialization of a static data member of a template or an explicit specialization of a static data member template is a definition if the declaration includes an initializer; otherwise, it is a declaration. [ *Note*: The definition of a static data member of a template that requires default-initialization must use a *braced-init-list*:

```
template<> X Q<int>::x;                      // declaration
template<> X Q<int>::x ();                     // error: declares a function
template<> X Q<int>::x { };                   // definition
```

— end note ]

- 15 A member or a member template of a class template may be explicitly specialized for a given implicit instantiation of the class template, even if the member or member template is defined in the class template definition. An explicit specialization of a member or member template is specified using the syntax for explicit specialization. [ *Example*:

```
template<class T> struct A {
    void f(T);
    template<class X1> void g1(T, X1);
    template<class X2> void g2(T, X2);
    void h(T) { }
};
```

```

// specialization
template<> void A<int>::f(int);

// out of class member template definition
template<class T> template<class X1> void A<T>::g1(T, X1) { }

// member template specialization
template<> template<class X1> void A<int>::g1(int, X1);

// member template specialization
template<> template<>
    void A<int>::g1(int, char);           // X1 deduced as char
template<> template<>
    void A<int>::g2<char>(int, char);   // X2 specified as char

// member specialization even if defined in class definition
template<> void A<int>::h(int) { }

— end example]

```

- <sup>16</sup> A member or a member template may be nested within many enclosing class templates. In an explicit specialization for such a member, the member declaration shall be preceded by a `template<>` for each enclosing class template that is explicitly specialized. [Example:

```

template<class T1> class A {
    template<class T2> class B {
        void mf();
    };
    template<> template<> class A<int>::B<double>;
    template<> template<> void A<char>::B<char>::mf();
}

— end example]

```

- <sup>17</sup> In an explicit specialization declaration for a member of a class template or a member template that appears in namespace scope, the member template and some of its enclosing class templates may remain unspecialized, except that the declaration shall not explicitly specialize a class member template if its enclosing class templates are not explicitly specialized as well. In such explicit specialization declaration, the keyword `template` followed by a *template-parameter-list* shall be provided instead of the `template<>` preceding the explicit specialization declaration of the member. The types of the *template-parameters* in the *template-parameter-list* shall be the same as those specified in the primary template definition. [Example:

```

template <class T1> class A {
    template<class T2> class B {
        template<class T3> void mf1(T3);
        void mf2();
    };
};

template <> template <class X>
class A<int>::B {
    template <class T> void mf1(T);
};

```

```

template <> template <> template<class T>
    void A<int>::B<double>::mf1(T t) { }
template <class Y> template <>
    void A<Y>::B<double>::mf2() { }           // ill-formed; B<double> is specialized but
                                                // its enclosing class template A is not
— end example]

```

- 18 A specialization of a member function template, member class template, or static data member template of a non-specialized class template is itself a template.
- 19 An explicit specialization declaration shall not be a friend declaration.
- 20 Default function arguments shall not be specified in a declaration or a definition for one of the following explicit specializations:
  - (20.1) — the explicit specialization of a function template;
  - (20.2) — the explicit specialization of a member function template;
  - (20.3) — the explicit specialization of a member function of a class template where the class template specialization to which the member function specialization belongs is implicitly instantiated. [Note: Default function arguments may be specified in the declaration or definition of a member function of a class template specialization that is explicitly specialized. — end note]

## 17.9 Function template specializations

[temp.fct.spec]

- 1 A function instantiated from a function template is called a function template specialization; so is an explicit specialization of a function template. Template arguments can be explicitly specified when naming the function template specialization, deduced from the context (e.g., deduced from the function arguments in a call to the function template specialization, see ??), or obtained from default template arguments.
- 2 Each function template specialization instantiated from a template has its own copy of any static variable. [Example:

```

template<class T> void f(T* p) {
    static T s;
}

void g(int a, char* b) {
    f(&a);           // calls f<int>(int*)
    f(&b);           // calls f<char*>(char**)
}

```

Here `f<int>(int*)` has a static variable `s` of type `int` and `f<char*>(char**)` has a static variable `s` of type `char*`. — end example]

### 17.9.1 Explicit template argument specification

[temp.arg.explicit]

- 1 Template arguments can be specified when referring to a function template specialization by qualifying the function template name with the list of *template-arguments* in the same way as *template-arguments* are specified in uses of a class template specialization. [Example:

```

template<class T> void sort(Array<T>& v);
void f(Array<dcomplex>& cv, Array<int>& ci) {
    sort<dcomplex>(cv);           // sort(Array<dcomplex>&)
}

```

```

    sort<int>(ci);           // sort(Array<int>&)
}

and

template<class U, class V> U convert(V v);

void g(double d) {
    int i = convert<int,double>(d);      // int convert(double)
    char c = convert<char,double>(d);     // char convert(double)
}

— end example]

```

- 2 A template argument list may be specified when referring to a specialization of a function template
- (2.1) — when a function is called,
  - (2.2) — when the address of a function is taken, when a function initializes a reference to function, or when a pointer to member function is formed,
  - (2.3) — in an explicit specialization,
  - (2.4) — in an explicit instantiation, or
  - (2.5) — in a friend declaration.
- 3 Trailing template arguments that can be deduced (??) or obtained from default *template-arguments* may be omitted from the list of explicit *template-arguments*. A trailing template parameter pack (??) not otherwise deduced will be deduced to an empty sequence of template arguments. If all of the template arguments can be deduced, they may all be omitted; in this case, the empty template argument list <> itself may also be omitted. In contexts where deduction is done and fails, or in contexts where deduction is not done, if a template argument list is specified and it, along with any default template arguments, identifies a single function template specialization, then the *template-id* is an lvalue for the function template specialization.

[*Example*:

```

template<class X, class Y> X f(Y);
template<class X, class Y, class ... Z> X g(Y);
void h() {
    int i = f<int>(5.6);           // Y is deduced to be double
    int j = f(5.6);                // ill-formed: X cannot be deduced
    f<void>(f<int, bool>);       // Y for outer f deduced to be int (*)(bool)
    f<void>(f<int>);            // ill-formed: f<int> does not denote a single function template specialization
    int k = g<int>(5.6);          // Y is deduced to be double, Z is deduced to an empty sequence
    f<void>(g<int, bool>);       // Y for outer f is deduced to be int (*)(bool),
                                // Z is deduced to an empty sequence
}

```

— end example]

- 4 [Note: An empty template argument list can be used to indicate that a given use refers to a specialization of a function template even when a non-template function (??) is visible that would otherwise be used. For example:

```

template <class T> int f(T);    // #1
int f(int);                   // #2
int k = f(1);                 // uses #2

```

```
int l = f<>(1); // uses #1
— end note]
```

- 5 Template arguments that are present shall be specified in the declaration order of their corresponding *template-parameters*. The template argument list shall not specify more *template-arguments* than there are corresponding *template-parameters* unless one of the *template-parameters* is a template parameter pack. [ *Example*:

```
template<class X, class Y, class Z> X f(Y,Z);
template<class ... Args> void f2();
void g() {
    f<int,const char*,double>("aa",3.0);
    f<int,const char*>("aa",3.0); // Z is deduced to be double
    f<int>("aa",3.0);           // Y is deduced to be const char*, and Z is deduced to be double
    f("aa",3.0);               // error: X cannot be deduced
    f2<char, short, int, long>(); // OK
}
```

— end example]

- 6 Implicit conversions (??) will be performed on a function argument to convert it to the type of the corresponding function parameter if the parameter type contains no *template-parameters* that participate in template argument deduction. [ *Note*: Template parameters do not participate in template argument deduction if they are explicitly specified. For example,

```
template<class T> void f(T);

class Complex {
    Complex(double);
};

void g() {
    f<Complex>(1); // OK, means f<Complex>(Complex(1))
}
```

— end note]

- 7 [ *Note*: Because the explicit template argument list follows the function template name, and because conversion member function templates and constructor member function templates are called without using a function name, there is no way to provide an explicit template argument list for these function templates. — end note]

- 8 Template argument deduction can extend the sequence of template arguments corresponding to a template parameter pack, even when the sequence contains explicitly specified template arguments. [ *Example*:

```
template<class ... Types> void f(Types ... values);

void g() {
    f<int*, float*>(0, 0, 0); // Types is deduced to the sequence int*, float*, int
}

— end example]
```

### 17.9.2 Template argument deduction

[temp.deduct]

- <sup>1</sup> When a function template specialization is referenced, all of the template arguments shall have values. The values can be explicitly specified or, in some cases, be deduced from the use or obtained from default template-arguments. [Example:

```
void f(Array<dcomplex>& cv, Array<int>& ci) {
    sort(cv);           // calls sort(Array<dcomplex>&)
    sort(ci);          // calls sort(Array<int>&)
}
```

and

```
void g(double d) {
    int i = convert<int>(d);      // calls convert<int,double>(double)
    int c = convert<char>(d);     // calls convert<char,double>(double)
}
```

— end example]

- <sup>2</sup> When an explicit template argument list is specified, if the template arguments are not compatible with the template parameter list or do not result in a valid function type as described below, type deduction fails. Specifically, the following steps are performed when evaluating an explicitly specified template argument list with respect to a given function template:

- (2.1) — If the specified template arguments do not match the template parameters in kind (i.e., type, non-type, template), or if there are more arguments than there are parameters and no parameter is a template parameter pack, or if there is not an argument for each non-pack parameter, type deduction fails.
  - (2.2) — If any non-type argument does not match the type of the corresponding non-type template parameter, and is not convertible to the type of the corresponding non-type parameter as specified in ??, type deduction fails.
  - (2.3) — The specified template argument values are substituted for the corresponding template parameters as specified below.
- 3 After this substitution is performed, the function parameter type adjustments described in ?? are performed. [Example: A parameter type of “void (const int, int[5])” becomes “void(\*)(int,int\*)”. — end example] [Note: A top-level qualifier in a function parameter declaration does not affect the function type but still affects the type of the function parameter variable within the function. — end note] [Example:

```
template <class T> void f(T t);
template <class X> void g(const X x);
template <class Z> void h(Z, Z*);

int main() {
    // #1: function type is f(int), t is non const
    f<int>(1);

    // #2: function type is f(int), t is const
    f<const int>(1);

    // #3: function type is g(int), x is const
    g<int>(1);
```

```
// #4: function type is g(int), x is const
g<const int>(1);

// #5: function type is h(int, const int*)
h<const int>(1,0);
}

— end example]
```

<sup>4</sup> [Note: `f<int>(1)` and `f<const int>(1)` call distinct functions even though both of the functions called have the same function type. — end note]

<sup>5</sup> The resulting substituted and adjusted function type is used as the type of the function template for template argument deduction. If a template argument has not been deduced and its corresponding template parameter has a default argument, the template argument is determined by substituting the template arguments determined for preceding template parameters into the default argument. If the substitution results in an invalid type, as described above, type deduction fails. [Example:

```
template <class T, class U = double>
void f(T t = 0, U u = 0);

void g() {
    f(1, 'c');           // f<int,char>(1,'c')
    f(1);               // f<int,double>(1,0)
    f();                // error: T cannot be deduced
    f<int>();           // f<int,double>(0,0)
    f<int,char>();      // f<int,char>(0,0)
}
```

— end example]

When all template arguments have been deduced or obtained from default template arguments, all uses of template parameters in the template parameter list of the template and the function type are replaced with the corresponding deduced or default argument values. If the substitution results in an invalid type, as described above, type deduction fails. If the function template has associated constraints (??), those constraints are checked for satisfaction (??). If the constraints are not satisfied, type deduction fails.

<sup>6</sup> At certain points in the template argument deduction process it is necessary to take a function type that makes use of template parameters and replace those template parameters with the corresponding template arguments. This is done at the beginning of template argument deduction when any explicitly specified template arguments are substituted into the function type, and again at the end of template argument deduction when any template arguments that were deduced or obtained from default arguments are substituted.

<sup>7</sup> The substitution occurs in all types and expressions that are used in the function type and in template parameter declarations. The expressions include not only constant expressions such as those that appear in array bounds or as nontype template arguments but also general expressions (i.e., non-constant expressions) inside `sizeof`, `decltype`, and other contexts that allow non-constant expressions. The substitution proceeds in lexical order and stops when a condition that causes deduction to fail is encountered. [Note: The equivalent substitution in exception specifications is done only when the `noexcept-specifier` is instantiated, at which point a program is ill-formed if the substitution results in an invalid type or expression. — end note] [Example:

```

template <class T> struct A { using X = typename T::X; };
template <class T> typename T::X f(typename A<T>::X);
template <class T> void f(...) { }
template <class T> auto g(typename A<T>::X) -> typename T::X;
template <class T> void g(...) { }

void h() {
    f<int>(0);           // OK, substituting return type causes deduction to fail
    g<int>(0);           // error, substituting parameter type instantiates A<int>
}

— end example ]

```

- <sup>8</sup> If a substitution results in an invalid type or expression, type deduction fails. An invalid type or expression is one that would be ill-formed, with a diagnostic required, if written using the substituted arguments. [ *Note:* If no diagnostic is required, the program is still ill-formed. Access checking is done as part of the substitution process. — *end note*] Only invalid types and expressions in the immediate context of the function type and its template parameter types can result in a deduction failure. [ *Note:* The substitution into types and expressions can result in effects such as the instantiation of class template specializations and/or function template specializations, the generation of implicitly-defined functions, etc. Such effects are not in the “immediate context” and can result in the program being ill-formed. — *end note* ]
- <sup>9</sup> A *lambda-expression* appearing in a function type or a template parameter is not considered part of the immediate context for the purposes of template argument deduction. [ *Note:* The intent is to avoid requiring implementations to deal with substitution failure involving arbitrary statements. [ *Example:*

```

template <class T>
    auto f(T) -> decltype([]() { T::invalid; } ());
void f(...);
f(0);           // error: invalid expression not part of the immediate context

template <class T, std::size_t = sizeof([]() { T::invalid; })>
    void g(T);
void g(...);
g(0);           // error: invalid expression not part of the immediate context

template <class T>
    auto h(T) -> decltype([x = T::invalid]());
void h(...);
h(0);           // error: invalid expression not part of the immediate context

template <class T>
    auto i(T) -> decltype([]() -> typename T::invalid { });
void i(...);
i(0);           // error: invalid expression not part of the immediate context

template <class T>
    auto j(T t) -> decltype([](auto x) -> decltype(x.invalid) { } (t)); // #1
void j(...);          // #2
j(0);           // deduction fails on #1, calls #2

```

— *end example*] — *end note* ]

<sup>10</sup> [ *Example:*

```
struct X { };
struct Y {
    Y(X){}
};

template <class T> auto f(T t1, T t2) -> decltype(t1 + t2);      // #1
X f(Y, Y);                                // #2

X x1, x2;
X x3 = f(x1, x2);    // deduction fails on #1 (cannot add X+X), calls #2
— end example]
```

<sup>11</sup> [ *Note:* Type deduction may fail for the following reasons:

- (11.1) — Attempting to instantiate a pack expansion containing multiple parameter packs of differing lengths.
- (11.2) — Attempting to create an array with an element type that is `void`, a function type, a reference type, or an abstract class type, or attempting to create an array with a size that is zero or negative. [ *Example:*

```
template <class T> int f(T[5]);
int I = f<int>(0);
int j = f<void>(0);           // invalid array
— end example]
```

- (11.3) — Attempting to use a type that is not a class or enumeration type in a qualified name. [ *Example:*

```
template <class T> int f(typename T::B*);
int i = f<int>(0);
— end example]
```

- (11.4) — Attempting to use a type in a *nested-name-specifier* of a *qualified-id* when that type does not contain the specified member, or
  - (11.4.1) — the specified member is not a type where a type is required, or
  - (11.4.2) — the specified member is not a template where a template is required, or
  - (11.4.3) — the specified member is not a non-type where a non-type is required.

[ *Example:*

```
template <int I> struct X {};
template <template <class T> class> struct Z {};
template <class T> void f(typename T::Y*){}
template <class T> void g(X<T::N*>) {}
template <class T> void h(Z<T::template TT*>) {}
struct A {};
struct B { int Y; };
struct C {
    typedef int N;
};
struct D {
    typedef int TT;
};
```

```

int main() {
    // Deduction fails in each of these cases:
    f<A>(0);           // A does not contain a member Y
    f<B>(0);           // The Y member of B is not a type
    g<C>(0);           // The N member of C is not a non-type
    h<D>(0);           // The TT member of D is not a template
}

```

— end example]

- (11.5) — Attempting to create a pointer to reference type.
  - (11.6) — Attempting to create a reference to `void`.
  - (11.7) — Attempting to create “pointer to member of T” when T is not a class type. [Example:
 

```

template <class T> int f(int T::*);
int i = f<int>(0);

```

 — end example]
  - (11.8) — Attempting to give an invalid type to a non-type template parameter. [Example:
 

```

template <class T, T> struct S {};
template <class T> int f(S<T, T()>*);
struct X {};
int i0 = f<X>(0);

```

 — end example]
  - (11.9) — Attempting to perform an invalid conversion in either a template argument expression, or an expression used in the function declaration. [Example:
 

```

template <class T, T*> int f(int);
int i2 = f<int,1>(0);           // can't conv 1 to int*

```

 — end example]
  - (11.10) — Attempting to create a function type in which a parameter has a type of `void`, or in which the return type is a function type or array type.
  - (11.11) — Attempting to create a function type in which a parameter type or the return type is an abstract class type (??).
- end note]

<sup>12</sup> [Example: In the following example, assuming a `signed char` cannot represent the value 1000, a narrowing conversion (??) would be required to convert the *template-argument* of type `int` to `signed char`, therefore substitution fails for the second template (??).]

```

template <int> int f(int);
template <signed char> int f(int);
int i1 = f<1000>(0);           // OK
int i2 = f<1>(0);             // ambiguous; not narrowing

```

— end example]

### 17.9.2.1 Deducing template arguments from a function call

[temp.deduct.call]

<sup>1</sup> Template argument deduction is done by comparing each function template parameter type (call it P) that contains *template-parameters* that participate in template argument deduction with the type of the

corresponding argument of the call (call it A) as described below. If removing references and cv-qualifiers from P gives `std::initializer_list<P'>` or `P'[N]` for some `P'` and `N` and the argument is a non-empty initializer list (??), then deduction is performed instead for each element of the initializer list, taking `P'` as a function template parameter type and the initializer element as its argument, and in the `P'[N]` case, if `N` is a non-type template parameter, `N` is deduced from the length of the initializer list. Otherwise, an initializer list argument causes the parameter to be considered a non-deduced context (??). [Example:

```
template<class T> void f(std::initializer_list<T>);  
f({1,2,3}); // T deduced to int  
f({1,"asdf"}); // error: T deduced to both int and const char*  
  
template<class T> void g(T);  
g({1,2,3}); // error: no argument deduced for T  
  
template<class T, int N> void h(T const(&)[N]);  
h({1,2,3}); // T deduced to int, N deduced to 3  
  
template<class T> void j(T const(&)[3]);  
j({42}); // T deduced to int, array bound not considered  
  
struct Aggr { int i; int j; };  
template<int N> void k(Aggr const(&)[N]);  
k({1,2,3}); // error: deduction fails, no conversion from int to Aggr  
k({{1},{2},{3}}); // OK, N deduced to 3  
  
template<int M, int N> void m(int const(&)[M][N]);  
m({{1,2},{3,4}}); // M and N both deduced to 2  
  
template<class T, int N> void n(T const(&)[N], T);  
n({{1},{2},{3}},Aggr()); // OK, T is Aggr, N is 3
```

—end example] For a function parameter pack that occurs at the end of the *parameter-declaration-list*, deduction is performed for each remaining argument of the call, taking the type P of the *declarator-id* of the function parameter pack as the corresponding function template parameter type. Each deduction deduces template arguments for subsequent positions in the template parameter packs expanded by the function parameter pack. When a function parameter pack appears in a non-deduced context (??), the type of that parameter pack is never deduced. [Example:

```
template<class ... Types> void f(Types& ...);  
template<class T1, class ... Types> void g(T1, Types ...);  
template<class T1, class ... Types> void g1(Types ..., T1);  
  
void h(int x, float& y) {  
    const int z = x;  
    f(x, y, z); // Types is deduced to int, float, const int  
    g(x, y, z); // T1 is deduced to int; Types is deduced to float, int  
    g1(x, y, z); // error: Types is not deduced  
    g1<int, int, int>(x, y, z); // OK, no deduction occurs  
}  
—end example]
```

<sup>2</sup> If P is not a reference type:

- (2.1) — If A is an array type, the pointer type produced by the array-to-pointer standard conversion (??) is used in place of A for type deduction; otherwise,
- (2.2) — If A is a function type, the pointer type produced by the function-to-pointer standard conversion (??) is used in place of A for type deduction; otherwise,
- (2.3) — If A is a cv-qualified type, the top-level cv-qualifiers of A's type are ignored for type deduction.

<sup>3</sup> If P is a cv-qualified type, the top-level cv-qualifiers of P's type are ignored for type deduction. If P is a reference type, the type referred to by P is used for type deduction. [Example:

```
template<class T> int f(const T&);
int n1 = f(5);                                // calls f<int>(const int&)
const int i = 0;
int n2 = f(i);                                 // calls f<int>(const int&)
template <class T> int g(volatile T&);
int n3 = g(i);                                 // calls g<const int>(const volatile int&)
```

— end example] A *forwarding reference* is an rvalue reference to a cv-unqualified template parameter that does not represent a template parameter of a class template (during class template argument deduction (??)). If P is a forwarding reference and the argument is an lvalue, the type “lvalue reference to A” is used in place of A for type deduction. [Example:

```
template <class T> int f(T&& heisenreference);
template <class T> int g(const T&&);

int i;
int n1 = f(i);                                // calls f<int&>(int&)
int n2 = f(0);                                 // calls f<int>(int&&)
int n3 = g(i);                                 // error: would call g<int>(const int&&), which
                                                // would bind an rvalue reference to an lvalue
```

```
template <class T> struct A {
    template <class U>
        A(T&&, U&&, int*);           // #1: T&& is not a forwarding reference.
                                            // U&& is a forwarding reference.
        A(T&&, int*);                // #2
};
```

```
template <class T> A(T&&, int*) -> A<T>;      // #3: T&& is a forwarding reference.
```

```
int *ip;
A a{i, 0, ip};                                // error: cannot deduce from #1
A a0{0, 0, ip};                               // uses #1 to deduce A<int> and #1 to initialize
A a2{i, ip};                                  // uses #3 to deduce A<int&> and #2 to initialize
```

— end example]

<sup>4</sup> In general, the deduction process attempts to find template argument values that will make the deduced A identical to A (after the type A is transformed as described above). However, there are three cases that allow a difference:

- (4.1) — If the original P is a reference type, the deduced A (i.e., the type referred to by the reference) can be more cv-qualified than the transformed A.

(4.2) — The transformed A can be another pointer or pointer-to-member type that can be converted to the deduced A via a function pointer conversion (??) and/or qualification conversion (??).

(4.3) — If P is a class and P has the form *simple-template-id*, then the transformed A can be a derived class of the deduced A. Likewise, if P is a pointer to a class of the form *simple-template-id*, the transformed A can be a pointer to a derived class pointed to by the deduced A.

<sup>5</sup> These alternatives are considered only if type deduction would otherwise fail. If they yield more than one possible deduced A, the type deduction fails. [ *Note*: If a *template-parameter* is not used in any of the function parameters of a function template, or is used only in a non-deduced context, its corresponding *template-argument* cannot be deduced from a function call and the *template-argument* must be explicitly specified. — *end note* ]

<sup>6</sup> When P is a function type, function pointer type, or pointer-to-member-function type:

(6.1) — If the argument is an overload set containing one or more function templates, the parameter is treated as a non-deduced context.

(6.2) — If the argument is an overload set (not containing function templates), trial argument deduction is attempted using each of the members of the set. If deduction succeeds for only one of the overload set members, that member is used as the argument value for the deduction. If deduction succeeds for more than one member of the overload set the parameter is treated as a non-deduced context.

<sup>7</sup> [ *Example*:

```
// Only one function of an overload set matches the call so the function parameter is a deduced context.
template <class T> int f(T (*p)(T));
int g(int);
int g(char);
int i = f(g);           // calls f(int (*)(int))

— end example]
```

<sup>8</sup> [ *Example*:

```
// Ambiguous deduction causes the second function parameter to be a non-deduced context.
template <class T> int f(T, T (*p)(T));
int g(int);
char g(char);
int i = f(1, g);        // calls f(int, int (*)(int))

— end example]
```

<sup>9</sup> [ *Example*:

```
// The overload set contains a template, causing the second function parameter to be a non-deduced context.
template <class T> int f(T, T (*p)(T));
char g(char);
template <class T> T g(T);
int i = f(1, g);        // calls f(int, int (*)(int))

— end example]
```

<sup>10</sup> If deduction succeeds for all parameters that contain *template-parameters* that participate in template argument deduction, and all template arguments are explicitly specified, deduced, or obtained from default template arguments, remaining parameters are then compared with the corresponding arguments. For each remaining parameter P with a type that was non-dependent before substitution of any explicitly-specified template arguments, if the corresponding argument A cannot be implicitly converted to P, deduction fails.

[*Note:* Parameters with dependent types in which no *template-parameters* participate in template argument deduction, and parameters that became non-dependent due to substitution of explicitly-specified template arguments, will be checked during overload resolution. — *end note*] [*Example:*

```
template <class T> struct Z {
    typedef typename T::x xx;
};

template <class T> typename Z<T>::xx f(void *, T);      // #1
template <class T> void f(int, T);                      // #2
struct A {} a;
int main() {
    f(1, a);           // OK, deduction fails for #1 because there is no conversion from int to void*
}
```

— *end example*]

### 17.9.2.2 Deducing template arguments taking the address of a function template [temp.deduct.funcaddr]

- <sup>1</sup> Template arguments can be deduced from the type specified when taking the address of an overloaded function (??). The function template's function type and the specified type are used as the types of P and A, and the deduction is done as described in ??.
- <sup>2</sup> A placeholder type (??) in the return type of a function template is a non-deduced context. If template argument deduction succeeds for such a function, the return type is determined from instantiation of the function body.

### 17.9.2.3 Deducing conversion function template arguments [temp.deduct.conv]

- <sup>1</sup> Template argument deduction is done by comparing the return type of the conversion function template (call it P) with the type that is required as the result of the conversion (call it A; see ??, ??, and ?? for the determination of that type) as described in ??.
- <sup>2</sup> If P is a reference type, the type referred to by P is used in place of P for type deduction and for any further references to or transformations of P in the remainder of this subclause.
- <sup>3</sup> If A is not a reference type:
  - (3.1) — If P is an array type, the pointer type produced by the array-to-pointer standard conversion (??) is used in place of P for type deduction; otherwise,
  - (3.2) — If P is a function type, the pointer type produced by the function-to-pointer standard conversion (??) is used in place of P for type deduction; otherwise,
  - (3.3) — If P is a cv-qualified type, the top-level cv-qualifiers of P's type are ignored for type deduction.
- <sup>4</sup> If A is a cv-qualified type, the top-level cv-qualifiers of A's type are ignored for type deduction. If A is a reference type, the type referred to by A is used for type deduction.
- <sup>5</sup> In general, the deduction process attempts to find template argument values that will make the deduced A identical to A. However, there are four cases that allow a difference:
  - (5.1) — If the original A is a reference type, A can be more cv-qualified than the deduced A (i.e., the type referred to by the reference)
  - (5.2) — If the original A is a function pointer type, A can be “pointer to function” even if the deduced A is “pointer to noexcept function”.

- (5.3) — If the original A is a pointer-to-member-function type, A can be “pointer to member of type function” even if the deduced A is “pointer to member of type noexcept function”.
- (5.4) — The deduced A can be another pointer or pointer-to-member type that can be converted to A via a qualification conversion.
- 6 These alternatives are considered only if type deduction would otherwise fail. If they yield more than one possible deduced A, the type deduction fails.
- 7 When the deduction process requires a qualification conversion for a pointer or pointer-to-member type as described above, the following process is used to determine the deduced template argument values:

If A is a type

$cv_{1,0}$  “pointer to ...”  $cv_{1,n-1}$  “pointer to”  $cv_{1,n}$  T1

and P is a type

$cv_{2,0}$  “pointer to ...”  $cv_{2,n-1}$  “pointer to”  $cv_{2,n}$  T2,

then the cv-unqualified T1 and T2 are used as the types of A and P respectively for type deduction.

[Example:

```
struct A {
    template <class T> operator T***();
};

A a;
const int * const * const * p1 = a;      // T is deduced as int, not const int
— end example]
```

#### 17.9.2.4 Deducing template arguments during partial ordering

[temp.deduct.partial]

- 1 Template argument deduction is done by comparing certain types associated with the two function templates being compared.
- 2 Two sets of types are used to determine the partial ordering. For each of the templates involved there is the original function type and the transformed function type. [Note: The creation of the transformed type is described in ??. — end note] The deduction process uses the transformed type as the argument template and the original type of the other template as the parameter template. This process is done twice for each type involved in the partial ordering comparison: once using the transformed template-1 as the argument template and template-2 as the parameter template and again using the transformed template-2 as the argument template and template-1 as the parameter template.
- 3 The types used to determine the ordering depend on the context in which the partial ordering is done:
  - (3.1) — In the context of a function call, the types used are those function parameter types for which the function call has arguments.<sup>144</sup>
  - (3.2) — In the context of a call to a conversion function, the return types of the conversion function templates are used.
  - (3.3) — In other contexts (??) the function template’s function type is used.
- 4 Each type nominated above from the parameter template and the corresponding type from the argument template are used as the types of P and A. If a particular P contains no *template-parameters* that participate in template argument deduction, that P is not used to determine the ordering.

---

<sup>144</sup>) Default arguments are not considered to be arguments in this context; they only become arguments after a function has been selected.

<sup>5</sup> Before the partial ordering is done, certain transformations are performed on the types used for partial ordering:

(5.1) — If P is a reference type, P is replaced by the type referred to.

(5.2) — If A is a reference type, A is replaced by the type referred to.

<sup>6</sup> If both P and A were reference types (before being replaced with the type referred to above), determine which of the two types (if any) is more cv-qualified than the other; otherwise the types are considered to be equally cv-qualified for partial ordering purposes. The result of this determination will be used below.

<sup>7</sup> Remove any top-level cv-qualifiers:

(7.1) — If P is a cv-qualified type, P is replaced by the cv-unqualified version of P.

(7.2) — If A is a cv-qualified type, A is replaced by the cv-unqualified version of A.

<sup>8</sup> Using the resulting types P and A, the deduction is then done as described in [??](#). If P is a function parameter pack, the type A of each remaining parameter type of the argument template is compared with the type P of the *declarator-id* of the function parameter pack. Each comparison deduces template arguments for subsequent positions in the template parameter packs expanded by the function parameter pack. Similarly, if A was transformed from a function parameter pack, it is compared with each remaining parameter type of the parameter template. If deduction succeeds for a given type, the type from the argument template is considered to be at least as specialized as the type from the parameter template. [ *Example*:

```
template<class... Args> void f(Args... args); // #1
template<class T1, class... Args> void f(T1 a1, Args... args); // #2
template<class T1, class T2> void f(T1 a1, T2 a2); // #3

f(); // calls #1
f(1, 2, 3); // calls #2
f(1, 2); // calls #3; non-variadic template #3 is more specialized
           // than the variadic templates #1 and #2
```

— end example ]

<sup>9</sup> If, for a given type, deduction succeeds in both directions (i.e., the types are identical after the transformations above) and both P and A were reference types (before being replaced with the type referred to above):

(9.1) — if the type from the argument template was an lvalue reference and the type from the parameter template was not, the parameter type is not considered to be at least as specialized as the argument type; otherwise,

(9.2) — if the type from the argument template is more cv-qualified than the type from the parameter template (as described above), the parameter type is not considered to be at least as specialized as the argument type.

<sup>10</sup> Function template F is *at least as specialized as* function template G if, for each pair of types used to determine the ordering, the type from F is at least as specialized as the type from G. F is *more specialized than* G if F is at least as specialized as G and G is not at least as specialized as F.

<sup>11</sup> If, after considering the above, function template F is at least as specialized as function template G and vice-versa, and if G has a trailing parameter pack for which F does not have a corresponding parameter, and if F does not have a trailing parameter pack, then F is more specialized than G.

<sup>12</sup> In most cases, deduction fails if not all template parameters have values, but for partial ordering purposes a template parameter may remain without a value provided it is not used in the types being used for partial

ordering. [ *Note:* A template parameter used in a non-deduced context is considered used. — *end note* ]  
 [ *Example:*

```
template <class T> T f(int);           // #1
template <class T, class U> T f(U);    // #2
void g() {
    f<int>(1);                      // calls #1
}
```

— *end example* ]

13 [ *Note:* Partial ordering of function templates containing template parameter packs is independent of the number of deduced arguments for those template parameter packs. — *end note* ] [ *Example:*

```
template<class ...> struct Tuple { };
template<class ... Types> void g(Tuple<Types ...>);           // #1
template<class T1, class ... Types> void g(Tuple<T1, Types ...>); // #2
template<class T1, class ... Types> void g(Tuple<T1, Types& ...>); // #3

g(Tuple<>());          // calls #1
g(Tuple<int, float>()); // calls #2
g(Tuple<int, float&>()); // calls #3
g(Tuple<int>());        // calls #3
```

— *end example* ]

### 17.9.2.5 Deducing template arguments from a type

[temp.deduct.type]

- <sup>1</sup> Template arguments can be deduced in several different contexts, but in each case a type that is specified in terms of template parameters (call it P) is compared with an actual type (call it A), and an attempt is made to find template argument values (a type for a type parameter, a value for a non-type parameter, or a template for a template parameter) that will make P, after substitution of the deduced values (call it the deduced A), compatible with A.
- <sup>2</sup> In some cases, the deduction is done using a single set of types P and A, in other cases, there will be a set of corresponding types P and A. Type deduction is done independently for each P/A pair, and the deduced template argument values are then combined. If type deduction cannot be done for any P/A pair, or if for any pair the deduction leads to more than one possible set of deduced values, or if different pairs yield different deduced values, or if any template argument remains neither deduced nor explicitly specified, template argument deduction fails. The type of a type parameter is only deduced from an array bound if it is not otherwise deduced.
- <sup>3</sup> A given type P can be composed from a number of other types, templates, and non-type values:
  - (3.1) — A function type includes the types of each of the function parameters and the return type.
  - (3.2) — A pointer-to-member type includes the type of the class object pointed to and the type of the member pointed to.
  - (3.3) — A type that is a specialization of a class template (e.g., A<int>) includes the types, templates, and non-type values referenced by the template argument list of the specialization.
  - (3.4) — An array type includes the array element type and the value of the array bound.
- <sup>4</sup> In most cases, the types, templates, and non-type values that are used to compose P participate in template argument deduction. That is, they may be used to determine the value of a template argument, and template argument deduction fails if the value so determined is not consistent with the values determined elsewhere.

In certain contexts, however, the value does not participate in type deduction, but instead uses the values of template arguments that were either deduced elsewhere or explicitly specified. If a template parameter is used only in non-deduced contexts and is not explicitly specified, template argument deduction fails. [ *Note: Under ?? and ??, if P contains no template-parameters that appear in deduced contexts, no deduction is done, so P and A need not have the same form. — end note* ]

5 The non-deduced contexts are:

- (5.1) — The *nested-name-specifier* of a type that was specified using a *qualified-id*.
  - (5.2) — The *expression* of a *decltype-specifier*.
  - (5.3) — A non-type template argument or an array bound in which a subexpression references a template parameter.
  - (5.4) — A template parameter used in the parameter type of a function parameter that has a default argument that is being used in the call for which argument deduction is being done.
  - (5.5) — A function parameter for which argument deduction cannot be done because the associated function argument is a function, or a set of overloaded functions (??), and one or more of the following apply:
    - (5.5.1) — more than one function matches the function parameter type (resulting in an ambiguous deduction), or
    - (5.5.2) — no function matches the function parameter type, or
    - (5.5.3) — the set of functions supplied as an argument contains one or more function templates.
  - (5.6) — A function parameter for which the associated argument is an initializer list (??) but the parameter does not have a type for which deduction from an initializer list is specified (??). [ *Example:*
- ```
template<class T> void g(T);
g({1,2,3}); // error: no argument deduced for T
— end example]
```
- (5.7) — A function parameter pack that does not occur at the end of the *parameter-declaration-list*.

6 When a type name is specified in a way that includes a non-deduced context, all of the types that comprise that type name are also non-deduced. However, a compound type can include both deduced and non-deduced types. [ *Example: If a type is specified as A<T>::B<T2>, both T and T2 are non-deduced. Likewise, if a type is specified as A<I+J>::X<T>, I, J, and T are non-deduced. If a type is specified as void f(typename A<T>::B, A<T>), the T in A<T>::B is non-deduced but the T in A<T> is deduced. — end example* ]

7 [ *Example: Here is an example in which different parameter/argument pairs produce inconsistent template argument deductions:*

```
template<class T> void f(T x, T y) { /* ... */ }
struct A { /* ... */ };
struct B : A { /* ... */ };
void g(A a, B b) {
    f(a,b); // error: T could be A or B
    f(b,a); // error: T could be A or B
    f(a,a); // OK: T is A
    f(b,b); // OK: T is B
}
```

Here is an example where two template arguments are deduced from a single function parameter/argument pair. This can lead to conflicts that cause type deduction to fail:

```

template <class T, class U> void f( T (*)( T, U, U ) );
int g1( int, float, float);
char g2( int, float, float);
int g3( int, char, float);

void r() {
    f(g1);           // OK: T is int and U is float
    f(g2);           // error: T could be char or int
    f(g3);           // error: U could be char or float
}

```

Here is an example where a qualification conversion applies between the argument type on the function call and the deduced template argument type:

```

template<class T> void f(const T*) { }
int* p;
void s() {
    f(p);           // f(const int*)
}

```

Here is an example where the template argument is used to instantiate a derived class type of the corresponding function parameter type:

```

template <class T> struct B { };
template <class T> struct D : public B<T> {};
struct D2 : public B<int> {};
template <class T> void f(B<T>&){}
void t() {
    D<int> d;
    D2      d2;
    f(d);           // calls f(B<int>&)
    f(d2);          // calls f(B<int>&)
}

```

— end example ]

- <sup>8</sup> A template type argument T, a template template argument TT or a template non-type argument i can be deduced if P and A have one of the following forms:

```

T
cv T
T*
T&
T&&
T[integer-constant]
template-name<T>  (where template-name refers to a class template)
type(T)
T()
T(T)
T type::*
type T::*
T T::*
T (type::*)()

```

```

type (T::*)()
type (type::*)(T)
type (T::*)(T)
T (type::*)(T)
T (T::*)()
T (T::*)(T)
type[i]
template-name<i> (where template-name refers to a class template)
TT<T>
TT<i>
TT<>

```

where (T) represents a parameter-type-list (??) where at least one parameter type contains a T, and () represents a parameter-type-list where no parameter type contains a T. Similarly, <T> represents template argument lists where at least one argument contains a T, <i> represents template argument lists where at least one argument contains an i and <> represents template argument lists where no argument contains a T or an i.

- <sup>9</sup> If P has a form that contains <T> or <i>, then each argument  $P_i$  of the respective template argument list of P is compared with the corresponding argument  $A_i$  of the corresponding template argument list of A. If the template argument list of P contains a pack expansion that is not the last template argument, the entire template argument list is a non-deduced context. If  $P_i$  is a pack expansion, then the pattern of  $P_i$  is compared with each remaining argument in the template argument list of A. Each comparison deduces template arguments for subsequent positions in the template parameter packs expanded by  $P_i$ . During partial ordering (??), if  $A_i$  was originally a pack expansion:

- (9.1) — if P does not contain a template argument corresponding to  $A_i$  then  $A_i$  is ignored;
- (9.2) — otherwise, if  $P_i$  is not a pack expansion, template argument deduction fails.

[ Example:

```

template<class T1, class... Z> class S;                                // #1
template<class T1, class... Z> class S<T1, const Z&...> { };          // #2
template<class T1, class T2>    class S<T1, const T2&> { };           // #3
S<int, const int&> s;        // both #2 and #3 match; #3 is more specialized

template<class T, class... U>      struct A { };                      // #1
template<class T1, class T2, class... U> struct A<T1, T2*, U...> { }; // #2
template<class T1, class T2>       struct A<T1, T2> { };            // #3
template struct A<int, int*>; // selects #2

```

— end example]

- <sup>10</sup> Similarly, if P has a form that contains (T), then each parameter type  $P_i$  of the respective parameter-type-list (??) of P is compared with the corresponding parameter type  $A_i$  of the corresponding parameter-type-list of A. If P and A are function types that originated from deduction when taking the address of a function template (??) or when deducing template arguments from a function declaration (??) and  $P_i$  and  $A_i$  are parameters of the top-level parameter-type-list of P and A, respectively,  $P_i$  is adjusted if it is a forwarding reference (??) and  $A_i$  is an lvalue reference, in which case the type of  $P_i$  is changed to be the template parameter type (i.e., T&& is changed to simply T). [ Note: As a result, when  $P_i$  is T&& and  $A_i$  is X&, the adjusted  $P_i$  will be T, causing T to be deduced as X&. — end note] [ Example:

```
template <class T> void f(T&&);
```

```

template <> void f(int&) { }      // #1
template <> void f(int&&) { }    // #2
void g(int i) {
    f(i);                      // calls f<int&>(int&), i.e., #1
    f(0);                      // calls f<int>(int&&), i.e., #2
}
— end example]

```

If the *parameter-declaration* corresponding to  $P_i$  is a function parameter pack, then the type of its *declarator-id* is compared with each remaining parameter type in the parameter-type-list of A. Each comparison deduces template arguments for subsequent positions in the template parameter packs expanded by the function parameter pack. During partial ordering (??), if  $A_i$  was originally a function parameter pack:

- (10.1) — if P does not contain a function parameter type corresponding to  $A_i$  then  $A_i$  is ignored;
- (10.2) — otherwise, if  $P_i$  is not a function parameter pack, template argument deduction fails.

[*Example*:

```

template<class T, class... U> void f(T*, U...) { } // #1
template<class T>           void f(T) { }          // #2
template void f(int*);           // selects #1
— end example]

```

- 11 These forms can be used in the same way as T is for further composition of types. [*Example*:

`X<int> (*)(char[6])`

is of the form

`template-name<T> (*)(type[i])`

which is a variant of

`type (*)(T)`

where type is `X<int>` and T is `char[6]`. — end example]

- 12 Template arguments cannot be deduced from function arguments involving constructs other than the ones specified above.
- 13 When the value of the argument corresponding to a non-type template parameter P that is declared with a dependent type is deduced from an expression, the template parameters in the type of P are deduced from the type of the value. [*Example*:

```

template<long n> struct A { };

template<typename T> struct C;
template<typename T, T n> struct C<A<n>> {
    using Q = T;
};

using R = long;
using R = C<A<2>>::Q;           // OK; T was deduced to long from the
                                    // template argument value in the type A<2>

```

— end example] The type of N in the type T[N] is `std::size_t`. [*Example*:

`template<typename T> struct S;`

```
template<typename T, T n> struct S<int[n]> {
    using Q = T;
};

using V = decltype(sizeof 0);
using V = S<int[42]>::Q;           // OK; T was deduced to std::size_t from the type int[42]
— end example]
```

<sup>14</sup> [Example:

```
template<class T, T i> void f(int (&a)[i]);
int v[10];
void g() {
    f(v);                  // OK: T is std::size_t
}
```

— end example]

<sup>15</sup> [Note: Except for reference and pointer types, a major array bound is not part of a function parameter type and cannot be deduced from an argument:

```
template<int i> void f1(int a[10][i]);
template<int i> void f2(int a[i][20]);
template<int i> void f3(int (&a)[i][20]);

void g() {
    int v[10][20];
    f1(v);                // OK: i deduced to be 20
    f1<20>(v);           // OK
    f2(v);                // error: cannot deduce template-argument i
    f2<10>(v);           // OK
    f3(v);                // OK: i deduced to be 10
}
```

— end note]

<sup>16</sup> [Note: If, in the declaration of a function template with a non-type template parameter, the non-type template parameter is used in a subexpression in the function parameter list, the expression is a non-deduced context as specified above. [Example:

```
template <int i> class A { /* ... */ };
template <int i> void g(A<i+1>);
template <int i> void f(A<i>, A<i+1>);
void k() {
    A<1> a1;
    A<2> a2;
    g(a1);                // error: deduction fails for expression i+1
    g<0>(a1);             // OK
    f(a1, a2);             // OK
}
```

— end example] — end note]

<sup>17</sup> [Note: Template parameters do not participate in template argument deduction if they are used only in non-deduced contexts. For example,

```

template<int i, typename T>
T deduce(typename A<T>::X x,      // T is not deduced here
          T t,                  // but T is deduced here
          typename B<i>::Y y); // i is not deduced here
A<int> a;
B<77> b;

int x = deduce<77>(a.xm, 62, b.ym);
// T is deduced to be int, a.xm must be convertible to A<int>::X
// i is explicitly specified to be 77, b.ym must be convertible to B<77>::Y
— end note]

```

- <sup>18</sup> If P has a form that contains *<i>*, and if the type of *i* differs from the type of the corresponding template parameter of the template named by the enclosing *simple-template-id*, deduction fails. If P has a form that contains *[i]*, and if the type of *i* is not an integral type, deduction fails.<sup>145</sup> [Example:

```

template<int i> class A { /* ... */ };
template<short s> void f(A<s>);
void k1() {
    A<1> a;
    f(a);           // error: deduction fails for conversion from int to short
    f<1>(a);       // OK
}

template<const short cs> class B { };
template<short s> void g(B<s>);
void k2() {
    B<1> b;
    g(b);           // OK: cv-qualifiers are ignored on template parameter types
}

```

— end example]

- <sup>19</sup> A *template-argument* can be deduced from a function, pointer to function, or pointer-to-member-function type.

[Example:

```

template<class T> void f(void()(T,int));
template<class T> void foo(T,int);
void g(int,int);
void g(char,int);

void h(int,int,int);
void h(char,int);
int m() {
    f(&g);           // error: ambiguous
    f(&h);           // OK: void h(char,int) is a unique match
    f(&foo);         // error: type deduction fails because foo is a template
}

```

---

<sup>145</sup>) Although the *template-argument* corresponding to a *template-parameter* of type `bool` may be deduced from an array bound, the resulting value will always be `true` because the array bound will be nonzero.

— end example]

- 20 A template *type-parameter* cannot be deduced from the type of a function default argument. [Example:

```
template <class T> void f(T = 5, T = 7);
void g() {
    f(1);           // OK: call f<int>(1,7)
    f();            // error: cannot deduce T
    f<int>();      // OK: call f<int>(5,7)
}
```

— end example]

- 21 The *template-argument* corresponding to a template *template-parameter* is deduced from the type of the *template-argument* of a class template specialization used in the argument list of a function call. [Example:

```
template <template <class T> class X> struct A { };
template <template <class T> class X> void f(A<X>) { }
template<class T> struct B { };
A<B> ab;
f(ab);           // calls f(A<B>)
```

— end example]

- 22 [Note: Template argument deduction involving parameter packs (??) can deduce zero or more arguments for each parameter pack. — end note] [Example:

```
template<class> struct X { };
template<class R, class ... ArgTypes> struct X<R(int, ArgTypes ...)> { };
template<class ... Types> struct Y { };
template<class T, class ... Types> struct Y<T, Types& ...> { };

template<class ... Types> int f(void (*)(Types ...));
void g(int, float);

X<int> x1;           // uses primary template
X<int(int, float, double)> x2; // uses partial specialization; ArgTypes contains float, double
X<int(float, int)> x3;        // uses primary template
Y<> y1;              // use primary template; Types is empty
Y<int&, float&, double&> y2; // uses partial specialization; T is int&, Types contains float, double
Y<int, float, double> y3;     // uses primary template; Types contains int, float, double
int fv = f(g);         // OK; Types contains int, float
```

— end example]

### 17.9.2.6 Deducing template arguments from a function declaration

[temp.deduct.decl]

- 1 In a declaration whose *declarator-id* refers to a specialization of a function template, template argument deduction is performed to identify the specialization to which the declaration refers. Specifically, this is done for explicit instantiations (??), explicit specializations (??), and certain friend declarations (??). This is also done to determine whether a deallocation function template specialization matches a placement `operator new` (??, ??). In all these cases, P is the type of the function template being considered as a potential match and A is either the function type from the declaration or the type of the deallocation function that would match the placement `operator new` as described in ???. The deduction is done as described in ??.

- <sup>2</sup> If, for the set of function templates so considered, there is either no match or more than one match after partial ordering has been considered (??), deduction fails and, in the declaration cases, the program is ill-formed.

### 17.9.3 Overload resolution

[temp.over]

- <sup>1</sup> A function template can be overloaded either by (non-template) functions of its name or by (other) function templates of the same name. When a call to that name is written (explicitly, or implicitly using the operator notation), template argument deduction (??) and checking of any explicit template arguments (??) are performed for each function template to find the template argument values (if any) that can be used with that function template to instantiate a function template specialization that can be invoked with the call arguments. For each function template, if the argument deduction and checking succeeds, the *template-arguments* (deduced and/or explicit) are used to synthesize the declaration of a single function template specialization which is added to the candidate functions set to be used in overload resolution. If, for a given function template, argument deduction fails or the synthesized function template specialization would be ill-formed, no such function is added to the set of candidate functions for that template. The complete set of candidate functions includes all the synthesized declarations and all of the non-template overloaded functions of the same name. The synthesized declarations are treated like any other functions in the remainder of overload resolution, except as explicitly noted in ??.<sup>146</sup>

- <sup>2</sup> [Example:

```
template<class T> T max(T a, T b) { return a>b?a:b; }

void f(int a, int b, char c, char d) {
    int m1 = max(a,b);           // max(int a, int b)
    char m2 = max(c,d);         // max(char a, char b)
    int m3 = max(a,c);         // error: cannot generate max(int,char)
}
```

Adding the non-template function

```
int max(int,int);
```

to the example above would resolve the third call, by providing a function that could be called for `max(a,c)` after using the standard conversion of `char` to `int` for `c`. —end example]

- <sup>3</sup> [Example: Here is an example involving conversions on a function argument involved in *template-argument* deduction:

```
template<class T> struct B { /* ... */ };
template<class T> struct D : public B<T> { /* ... */ };
template<class T> void f(B<T>&);

void g(B<int>& bi, D<int>& di) {
    f(bi);                  // f(bi)
    f(di);                  // f((B<int>&)di)
}
```

—end example]

---

<sup>146</sup>) The parameters of function template specializations contain no template parameter types. The set of conversions allowed on deduced arguments is limited, because the argument deduction process produces function templates with parameters that either match the call arguments exactly or differ only in ways that can be bridged by the allowed limited conversions. Non-deduced arguments allow the full range of conversions. Note also that ?? specifies that a non-template function will be given preference over a template specialization if the two functions are otherwise equally good candidates for an overload match.

- <sup>4</sup> [Example: Here is an example involving conversions on a function argument not involved in *template-parameter* deduction:

```
template<class T> void f(T*,int);      // #1
template<class T> void f(T,char);      // #2

void h(int* pi, int i, char c) {
    f(pi,i);           // #1: f<int>(pi,i)
    f(pi,c);           // #2: f<int*>(pi,c)

    f(i,c);           // #2: f<int>(i,c);
    f(i,i);           // #2: f<int>(i,char(i))
}
```

— end example]

- <sup>5</sup> Only the signature of a function template specialization is needed to enter the specialization in a set of candidate functions. Therefore only the function template declaration is needed to resolve a call for which a template specialization is a candidate. [Example:

```
template<class T> void f(T);    // declaration

void g() {
    f("Annemarie");        // call of f<const char*>
}
```

The call of **f** is well-formed even if the template **f** is only declared and not defined at the point of the call. The program will be ill-formed unless a specialization for **f<const char\*>**, either implicitly or explicitly generated, is present in some translation unit. — end example]

## 17.10 Deduction guides

[temp.deduct.guide]

- <sup>1</sup> Deduction guides are used when a *template-name* appears as a type specifier for a deduced class type (??). Deduction guides are not found by name lookup. Instead, when performing class template argument deduction (??), any deduction guides declared for the class template are considered.

*deduction-guide*:

*explicit<sub>opt</sub>* *template-name* (*parameter-declaration-clause*) → *simple-template-id* ;

- <sup>2</sup> [Example:

```
template<class T, class D = int>
struct S {
    T data;
};

template<class U>
S(U) -> S<typename U::type>;

struct A {
    using type = short;
    operator type();
};

S x{A()};           // x is of type S<short, int>

— end example]
```

- <sup>3</sup> The same restrictions apply to the *parameter-declaration-clause* of a deduction guide as in a function declaration (??). The *simple-template-id* shall name a class template specialization. The *template-name* shall be the same *identifier* as the *template-name* of the *simple-template-id*. A *deduction-guide* shall be declared in the same scope as the corresponding class template and, for a member class template, with the same access. Two deduction guide declarations in the same translation unit for the same class template shall not have equivalent *parameter-declaration-clauses*.

# 18 Exception handling

[except]

- <sup>1</sup> Exception handling provides a way of transferring control and information from a point in the execution of a thread to an exception handler associated with a point previously passed by the execution. A handler will be invoked only by throwing an exception in code executed in the handler's try block or in functions called from the handler's try block.

```

try-block:
    try compound-statement handler-seq

function-try-block:
    try ctor-initializeropt compound-statement handler-seq

handler-seq:
    handler handler-seqopt

handler:
    catch ( exception-declaration ) compound-statement

exception-declaration:
    attribute-specifier-seqopt type-specifier-seq declarator
    attribute-specifier-seqopt type-specifier-seq abstract-declaratoropt
    ...

```

The optional *attribute-specifier-seq* in an *exception-declaration* appertains to the parameter of the catch clause (??).

- <sup>2</sup> A *try-block* is a *statement* (??). [Note: Within this Clause “try block” is taken to mean both *try-block* and *function-try-block*. — end note]

- <sup>3</sup> A **goto** or **switch** statement shall not be used to transfer control into a try block or into a handler.

[Example:

```

void f() {
    goto 11;           // ill-formed
    goto 12;           // ill-formed
    try {
        goto 11;       // OK
        goto 12;       // ill-formed
        11: ;
    } catch (...) {
        12: ;
        goto 11;       // ill-formed
        goto 12;       // OK
    }
}

```

— end example] A **goto**, **break**, **return**, or **continue** statement can be used to transfer control out of a try block or handler. When this happens, each variable declared in the try block will be destroyed in the context that directly contains its declaration. [Example:

```

lab: try {
    T1 t1;
}

```

```

try {
    T2 t2;
    if (condition)
        goto lab;
} catch(...) { /* handler 2 */ }
} catch(...) { /* handler 1 */ }

```

Here, executing `goto lab;` will destroy first `t2`, then `t1`, assuming the `condition` does not declare a variable. Any exception thrown while destroying `t2` will result in executing `handler 2`; any exception thrown while destroying `t1` will result in executing `handler 1`. —end example]

- <sup>4</sup> A *function-try-block* associates a *handler-seq* with the *ctor-initializer*, if present, and the *compound-statement*. An exception thrown during the execution of the *compound-statement* or, for constructors and destructors, during the initialization or destruction, respectively, of the class's subobjects, transfers control to a handler in a *function-try-block* in the same way as an exception thrown during the execution of a *try-block* transfers control to other handlers. [Example:

```

int f(int);
class C {
    int i;
    double d;
public:
    C(int, double);
};

C::C(int ii, double id)
try : i(f(ii)), d(id) {
    // constructor statements
} catch (...) {
    // handles exceptions thrown from the ctor-initializer and from the constructor statements
}

```

—end example]

- <sup>5</sup> In this Clause, “before” and “after” refer to the “sequenced before” relation (??).

## 18.1 Throwing an exception

[**except.throw**]

- <sup>1</sup> Throwing an exception transfers control to a handler. [Note: An exception can be thrown from one of the following contexts: *throw-expressions* (??), allocation functions (??), `dynamic_cast` (??), `typeid` (??), *new-expressions* (??), and standard library functions (??). —end note] An object is passed and the type of that object determines which handlers can catch it. [Example:

```
throw "Help!";
```

can be caught by a *handler* of `const char*` type:

```

try {
    // ...
} catch(const char* p) {
    // handle character string exceptions here
}

```

and

```

class Overflow {
public:
    Overflow(char,double,double);
};

void f(double x) {
    throw Overflow('+' ,x,3.45e107);
}

```

can be caught by a handler for exceptions of type `Overflow`:

```

try {
    f(1.2);
} catch(Overflow& oo) {
    // handle exceptions of type Overflow here
}

— end example]

```

- 2 When an exception is thrown, control is transferred to the nearest handler with a matching type (??); “nearest” means the handler for which the *compound-statement* or *ctor-initializer* following the `try` keyword was most recently entered by the thread of control and not yet exited.
- 3 Throwing an exception copy-initializes (??, ??) a temporary object, called the *exception object*. An lvalue denoting the temporary is used to initialize the variable declared in the matching *handler* (??). If the type of the exception object would be an incomplete type or a pointer to an incomplete type other than `cv void` the program is ill-formed.
- 4 The memory for the exception object is allocated in an unspecified way, except as noted in ???. If a handler exits by rethrowing, control is passed to another handler for the same exception object. The points of potential destruction for the exception object are:

- (4.1) — when an active handler for the exception exits by any means other than rethrowing, immediately after the destruction of the object (if any) declared in the *exception-declaration* in the handler;
- (4.2) — when an object of type `std::exception_ptr` (??) that refers to the exception object is destroyed, before the destructor of `std::exception_ptr` returns.

Among all points of potential destruction for the exception object, there is an unspecified last one where the exception object is destroyed. All other points happen before that last one (??). [Note: No other thread synchronization is implied in exception handling. — end note] The implementation may then deallocate the memory for the exception object; any such deallocation is done in an unspecified way. [Note: A thrown exception does not propagate to other threads unless caught, stored, and rethrown using appropriate library functions; see ?? and ???. — end note]

- 5 When the thrown object is a class object, the constructor selected for the copy-initialization as well as the constructor selected for a copy-initialization considering the thrown object as an lvalue shall be non-deleted and accessible, even if the copy/move operation is elided (??). The destructor is potentially invoked (??).
- 6 An exception is considered caught when a handler for that exception becomes active (??). [Note: An exception can have active handlers and still be considered uncaught if it is rethrown. — end note]
- 7 If the exception handling mechanism handling an uncaught exception (??) directly invokes a function that exits via an exception, `std::terminate` is called (??). [Example:

```

struct C {
    C() { }
    C(const C&) {
        if (std::uncaught_exception()) {
            throw 0;      // throw during copy to handler's exception-declaration object (??)
        }
    }
};

int main() {
    try {
        throw C();      // calls std::terminate() if construction of the handler's
                        // exception-declaration object is not elided (??)
    } catch(C) { }
}

```

—end example] [Note: Consequently, destructors should generally catch exceptions and not let them propagate. —end note]

## 18.2 Constructors and destructors

[**except.ctor**]

- <sup>1</sup> As control passes from the point where an exception is thrown to a handler, destructors are invoked by a process, specified in this subclause, called *stack unwinding*.
- <sup>2</sup> The destructor is invoked for each automatic object of class type constructed, but not yet destroyed, since the try block was entered. If an exception is thrown during the destruction of temporaries or local variables for a **return** statement (??), the destructor for the returned object (if any) is also invoked. The objects are destroyed in the reverse order of the completion of their construction. [*Example:*

```

struct A { };

struct Y { ~Y() noexcept(false) { throw 0; } };

A f() {
    try {
        A a;
        Y y;
        A b;
        return {};      // #1
    } catch (...) {
    }
    return {};      // #2
}

```

At #1, the returned object of type **A** is constructed. Then, the local variable **b** is destroyed (??). Next, the local variable **y** is destroyed, causing stack unwinding, resulting in the destruction of the returned object, followed by the destruction of the local variable **a**. Finally, the returned object is constructed again at #2. —end example]

- <sup>3</sup> If the initialization or destruction of an object other than by delegating constructor is terminated by an exception, the destructor is invoked for each of the object's direct subobjects and, for a complete object, virtual base class subobjects, whose initialization has completed (??) and whose destructor has not yet begun execution, except that in the case of destruction, the variant members of a union-like class are not destroyed.

The subobjects are destroyed in the reverse order of the completion of their construction. Such destruction is sequenced before entering a handler of the *function-try-block* of the constructor or destructor, if any.

- <sup>4</sup> If the *compound-statement* of the *function-body* of a delegating constructor for an object exits via an exception, the object's destructor is invoked. Such destruction is sequenced before entering a handler of the *function-try-block* of a delegating constructor for that object, if any.
- <sup>5</sup> [ *Note:* If the object was allocated by a *new-expression* (??), the matching deallocation function (??), if any, is called to free the storage occupied by the object. — *end note* ]

### 18.3 Handling an exception

[**except.handle**]

- <sup>1</sup> The *exception-declaration* in a *handler* describes the type(s) of exceptions that can cause that *handler* to be entered. The *exception-declaration* shall not denote an incomplete type, an abstract class type, or an rvalue reference type. The *exception-declaration* shall not denote a pointer or reference to an incomplete type, other than `void*`, `const void*`, `volatile void*`, or `const volatile void*`.
- <sup>2</sup> A handler of type “array of T” or function type T is adjusted to be of type “pointer to T”.
- <sup>3</sup> A *handler* is a match for an exception object of type E if
  - (3.1) — The *handler* is of type *cv T* or *cv T&* and E and T are the same type (ignoring the top-level *cv-qualifiers*), or
  - (3.2) — the *handler* is of type *cv T* or *cv T&* and T is an unambiguous public base class of E, or
  - (3.3) — the *handler* is of type *cv T* or *const T&* where T is a pointer or pointer-to-member type and E is a pointer or pointer-to-member type that can be converted to T by one or more of
    - (3.3.1) — a standard pointer conversion (??) not involving conversions to pointers to private or protected or ambiguous classes
    - (3.3.2) — a function pointer conversion (??)
    - (3.3.3) — a qualification conversion (??), or
  - (3.4) — the *handler* is of type *cv T* or *const T&* where T is a pointer or pointer-to-member type and E is `std::nullptr_t`.

[ *Note:* A *throw-expression* whose operand is an integer literal with value zero does not match a handler of pointer or pointer-to-member type. A handler of reference to array or function type is never a match for any exception object (??). — *end note* ]

[ *Example:*

```
class Matherr { /* ... */ virtual void vf(); };
class Overflow: public Matherr { /* ... */ };
class Underflow: public Matherr { /* ... */ };
class Zerodivide: public Matherr { /* ... */ };

void f() {
    try {
        g();
    } catch (Overflow oo) {
        // ...
    } catch (Matherr mm) {
        // ...
    }
}
```

}

Here, the `Overflow` handler will catch exceptions of type `Overflow` and the `Matherr` handler will catch exceptions of type `Matherr` and of all types publicly derived from `Matherr` including exceptions of type `Underflow` and `Zerodivide`. — *end example*]

- 4 The handlers for a try block are tried in order of appearance. [ *Note:* This makes it possible to write handlers that can never be executed, for example by placing a handler for a final derived class after a handler for a corresponding unambiguous public base class. — *end note* ]
- 5 A ... in a handler's *exception-declaration* functions similarly to ... in a function parameter declaration; it specifies a match for any exception. If present, a ... handler shall be the last handler for its try block.
- 6 If no match is found among the handlers for a try block, the search for a matching handler continues in a dynamically surrounding try block of the same thread.
- 7 A handler is considered *active* when initialization is complete for the parameter (if any) of the catch clause. [ *Note:* The stack will have been unwound at that point. — *end note* ] Also, an implicit handler is considered active when `std::terminate()` is entered due to a throw. A handler is no longer considered active when the catch clause exits.
- 8 The exception with the most recently activated handler that is still active is called the *currently handled exception*.
- 9 If no matching handler is found, the function `std::terminate()` is called; whether or not the stack is unwound before this call to `std::terminate()` is implementation-defined (??).
- 10 Referring to any non-static member or base class of an object in the handler for a *function-try-block* of a constructor or destructor for that object results in undefined behavior.
- 11 The scope and lifetime of the parameters of a function or constructor extend into the handlers of a *function-try-block*.
- 12 Exceptions thrown in destructors of objects with static storage duration or in constructors of namespace-scope objects with static storage duration are not caught by a *function-try-block* on the `main` function (??). Exceptions thrown in destructors of objects with thread storage duration or in constructors of namespace-scope objects with thread storage duration are not caught by a *function-try-block* on the initial function of the thread.
- 13 If a return statement appears in a handler of the *function-try-block* of a constructor, the program is ill-formed.
- 14 The currently handled exception is rethrown if control reaches the end of a handler of the *function-try-block* of a constructor or destructor. Otherwise, flowing off the end of the *compound-statement* of a *handler* of a *function-try-block* is equivalent to flowing off the end of the *compound-statement* of that function (see ??).
- 15 The variable declared by the *exception-declaration*, of type `cv T` or `cv T&`, is initialized from the exception object, of type `E`, as follows:
  - (15.1) — if `T` is a base class of `E`, the variable is copy-initialized (??) from the corresponding base class subobject of the exception object;
  - (15.2) — otherwise, the variable is copy-initialized (??) from the exception object.

The lifetime of the variable ends when the handler exits, after the destruction of any automatic objects initialized within the handler.

- <sup>16</sup> When the handler declares an object, any changes to that object will not affect the exception object. When the handler declares a reference to an object, any changes to the referenced object are changes to the exception object and will have effect should that object be rethrown.

## 18.4 Exception specifications

[except.spec]

- <sup>1</sup> The predicate indicating whether a function cannot exit via an exception is called the *exception specification* of the function. If the predicate is false, the function has a *potentially-throwing exception specification*, otherwise it has a *non-throwing exception specification*. The exception specification is either defined implicitly, or defined explicitly by using a *noexcept-specifier* as a suffix of a function declarator (??).

*noexcept-specifier*:

```
noexcept ( constant-expression )
noexcept
throw ( )
```

- <sup>2</sup> In a *noexcept-specifier*, the *constant-expression*, if supplied, shall be a contextually converted constant expression of type `bool` (??); that constant expression is the exception specification of the function type in which the *noexcept-specifier* appears. A ( token that follows `noexcept` is part of the *noexcept-specifier* and does not commence an initializer (??). The *noexcept-specifier* `noexcept` without a *constant-expression* is equivalent to the *noexcept-specifier* `noexcept(true)`. The *noexcept-specifier* `throw()` is deprecated (??), and equivalent to the *noexcept-specifier* `noexcept(true)`.
- <sup>3</sup> If a declaration of a function does not have a *noexcept-specifier*, the declaration has a potentially throwing exception specification unless it is a destructor or a deallocation function or is defaulted on its first declaration, in which cases the exception specification is as specified below and no other declaration for that function shall have a *noexcept-specifier*. In an explicit instantiation (??) a *noexcept-specifier* may be specified, but is not required. If a *noexcept-specifier* is specified in an explicit instantiation directive, the exception specification shall be the same as the exception specification of all other declarations of that function. A diagnostic is required only if the exception specifications are not the same within a single translation unit.
- <sup>4</sup> If a virtual function has a non-throwing exception specification, all declarations, including the definition, of any function that overrides that virtual function in any derived class shall have a non-throwing exception specification, unless the overriding function is defined as deleted. [ *Example*:

```
struct B {
    virtual void f() noexcept;
    virtual void g();
    virtual void h() noexcept = delete;
};

struct D: B {
    void f();                                // ill-formed
    void g() noexcept;                        // OK
    void h() = delete;                         // OK
};
```

The declaration of `D::f` is ill-formed because it has a potentially-throwing exception specification, whereas `B::f` has a non-throwing exception specification. — *end example* ]

- <sup>5</sup> Whenever an exception is thrown and the search for a handler (??) encounters the outermost block of a function with a non-throwing exception specification, the function `std::terminate()` is called (??). [ *Note*:

An implementation shall not reject an expression merely because, when executed, it throws or might throw an exception from a function with a non-throwing exception specification. — *end note*] [Example:

```
extern void f();           // potentially-throwing

void g() noexcept {
    f();                  // valid, even if f throws
    throw 42;              // valid, effectively a call to std::terminate
}
```

The call to `f` is well-formed even though, when called, `f` might throw an exception. — *end example*]

6 An expression `e` is *potentially-throwing* if

- (6.1) — `e` is a function call (??) whose *postfix-expression* has a function type, or a pointer-to-function type, with a potentially-throwing exception specification, or
- (6.2) — `e` implicitly invokes a function (such as an overloaded operator, an allocation function in a *new-expression*, a constructor for a function argument, or a destructor if `e` is a full-expression (??)) that is potentially-throwing, or
- (6.3) — `e` is a *throw-expression* (??), or
- (6.4) — `e` is a `dynamic_cast` expression that casts to a reference type and requires a runtime check (??), or
- (6.5) — `e` is a `typeid` expression applied to a (possibly parenthesized) built-in unary `*` operator applied to a pointer to a polymorphic class type (??), or
- (6.6) — any of the immediate subexpressions (??) of `e` is potentially-throwing.

7 An implicitly-declared constructor for a class `X`, or a constructor without a *noexcept-specifier* that is defaulted on its first declaration, has a potentially-throwing exception specification if and only if any of the following constructs is potentially-throwing:

- (7.1) — a constructor selected by overload resolution in the implicit definition of the constructor for class `X` to initialize a potentially constructed subobject, or
- (7.2) — a subexpression of such an initialization, such as a default argument expression, or,
- (7.3) — for a default constructor, a default member initializer.

[Note: Even though destructors for fully-constructed subobjects are invoked when an exception is thrown during the execution of a constructor (??), their exception specifications do not contribute to the exception specification of the constructor, because an exception thrown from such a destructor would call `std::terminate` rather than escape the constructor (??, ??). — *end note*]

- 8 The exception specification for an implicitly-declared destructor, or a destructor without a *noexcept-specifier*, is potentially-throwing if and only if any of the destructors for any of its potentially constructed subobjects is potentially throwing.
- 9 The exception specification for an implicitly-declared assignment operator, or an assignment-operator without a *noexcept-specifier* that is defaulted on its first declaration, is potentially-throwing if and only if the invocation of any assignment operator in the implicit definition is potentially-throwing.
- 10 A deallocation function (??) with no explicit *noexcept-specifier* has a non-throwing exception specification.
- 11 The exception specification for a comparison operator (??, ??, ??) without a *noexcept-specifier* that is defaulted on its first declaration is potentially-throwing if and only if the invocation of any comparison operator in the implicit definition is potentially-throwing.

<sup>12</sup> [ *Example:*

```

struct A {
    A(int = (A(5), 0)) noexcept;
    A(const A&) noexcept;
    A(A&&) noexcept;
    ~A();
};

struct B {
    B() throw();
    B(const B&) = default;           // implicit exception specification is noexcept(true)
    B(B&&, int = (throw Y(), 0)) noexcept;
    ~B() noexcept(false);
};

int n = 7;
struct D : public A, public B {
    int * p = new int[n];
    // D::D() potentially-throwing, as the new operator may throw bad_alloc or bad_array_new_length
    // D::D(const D&) non-throwing
    // D::D(D&&) potentially-throwing, as the default argument for B's constructor may throw
    // D::~D() potentially-throwing
};

```

Furthermore, if `A::~A()` were virtual, the program would be ill-formed since a function that overrides a virtual function from a base class shall not have a potentially-throwing exception specification if the base class function has a non-throwing exception specification. — *end example*]

<sup>13</sup> An exception specification is considered to be *needed* when:

- (13.1) — in an expression, the function is the unique lookup result or the selected member of a set of overloaded functions (??, ??, ??);
- (13.2) — the function is odr-used (??) or, if it appears in an unevaluated operand, would be odr-used if the expression were potentially-evaluated;
- (13.3) — the exception specification is compared to that of another declaration (e.g., an explicit specialization or an overriding virtual function);
- (13.4) — the function is defined; or
- (13.5) — the exception specification is needed for a defaulted special member function that calls the function.

[ *Note:* A defaulted declaration does not require the exception specification of a base member function to be evaluated until the implicit exception specification of the derived function is needed, but an explicit *noexcept-specifier* needs the implicit exception specification to compare against. — *end note*]

The exception specification of a defaulted special member function is evaluated as described above only when needed; similarly, the *noexcept-specifier* of a specialization of a function template or member function of a class template is instantiated only when needed.

## 18.5 Special functions

[`except.special`]

- <sup>1</sup> The function `std::terminate()` (??) is used by the exception handling mechanism for coping with errors related to the exception handling mechanism itself. The function `std::current_exception()` (??) and the class `std::nested_exception` (??) can be used by a program to capture the currently handled exception.

### 18.5.1 The `std::terminate()` function

[`except.terminate`]

- <sup>1</sup> In some situations exception handling must be abandoned for less subtle error handling techniques. [ *Note:* These situations are:

- (1.1) — when the exception handling mechanism, after completing the initialization of the exception object but before activation of a handler for the exception (??), calls a function that exits via an exception, or
- (1.2) — when the exception handling mechanism cannot find a handler for a thrown exception (??), or
- (1.3) — when the search for a handler (??) encounters the outermost block of a function with a non-throwing exception specification (??), or
- (1.4) — when the destruction of an object during stack unwinding (??) terminates by throwing an exception, or
- (1.5) — when initialization of a non-local variable with static or thread storage duration (??) exits via an exception, or
- (1.6) — when destruction of an object with static or thread storage duration exits via an exception (??), or
- (1.7) — when execution of a function registered with `std::atexit` or `std::at_quick_exit` exits via an exception (??), or
- (1.8) — when a *throw-expression* (??) with no operand attempts to rethrow an exception and no exception is being handled (??), or
- (1.9) — when the function `std::nested_exception::rethrow_nested` is called for an object that has captured no exception (??), or
- (1.10) — when execution of the initial function of a thread exits via an exception (??), or
- (1.11) — for a parallel algorithm whose `ExecutionPolicy` specifies such behavior (??, ??, ??), when execution of an element access function (??) of the parallel algorithm exits via an exception (??), or
- (1.12) — when the destructor or the copy assignment operator is invoked on an object of type `std::thread` that refers to a joinable thread (??, ??), or
- (1.13) — when a call to a `wait()`, `wait_until()`, or `wait_for()` function on a condition variable (??, ??) fails to meet a postcondition.

— *end note* ]

- <sup>2</sup> In such cases, `std::terminate()` is called (??). In the situation where no matching handler is found, it is implementation-defined whether or not the stack is unwound before `std::terminate()` is called. In the situation where the search for a handler (??) encounters the outermost block of a function with a non-throwing exception specification (??), it is implementation-defined whether the stack is unwound, unwound partially, or not unwound at all before `std::terminate()` is called. In all other situations, the stack shall not be unwound before `std::terminate()` is called. An implementation is not permitted to finish stack unwinding prematurely based on a determination that the unwind process will eventually cause a call to `std::terminate()`.

### 18.5.2 The `std::uncaught_exceptions()` function

[`except.uncaught`]

- <sup>1</sup> An exception is considered uncaught after completing the initialization of the exception object (??) until completing the activation of a handler for the exception (??). This includes stack unwinding. If an exception is rethrown (??, ??), it is considered uncaught from the point of rethrow until the rethrown exception is caught. The function `std::uncaught_exceptions()` (??) returns the number of uncaught exceptions in the current thread.

# 19 Preprocessing directives [cpp]

- <sup>1</sup> A *preprocessing directive* consists of a sequence of preprocessing tokens that satisfies the following constraints: The first token in the sequence is a # preprocessing token that (at the start of translation phase 4) is either the first character in the source file (optionally after white space containing no new-line characters) or that follows white space containing at least one new-line character. The last token in the sequence is the first new-line character that follows the first token in the sequence.<sup>147</sup> A new-line character ends the preprocessing directive even if it occurs within what would otherwise be an invocation of a function-like macro.

```

preprocessing-file:
  groupopt

group:
  group-part
  group group-part

group-part:
  control-line
  if-section
  text-line
  # conditionally-supported-directive

control-line:
  # include      pp-tokens new-line
  # define       identifier replacement-list new-line
  # define       identifier lparen identifier-listopt ) replacement-list new-line
  # define       identifier lparen ... ) replacement-list new-line
  # define       identifier lparen identifier-list , ... ) replacement-list new-line
  # undef        identifier new-line
  # line         pp-tokens new-line
  # error        pp-tokensopt new-line
  # pragma       pp-tokensopt new-line
  # new-line

if-section:
  if-group elif-groupsopt else-groupopt endif-line

if-group:
  # if           constant-expression new-line groupopt
  # ifdef        identifier new-line groupopt
  # ifndef       identifier new-line groupopt

elif-groups:
  elif-group
  elif-groups elif-group

elif-group:
  # elif         constant-expression new-line groupopt

```

---

<sup>147)</sup> Thus, preprocessing directives are commonly called “lines”. These “lines” have no other syntactic significance, as all white space is equivalent except in certain situations during preprocessing (see the # character string literal creation operator in ??, for example).

```

else-group:
  # else      new-line groupopt
endif-line:
  # endif     new-line
text-line:
  pp-tokensopt new-line
conditionally-supported-directive:
  pp-tokens new-line
lparen:
  a ( character not immediately preceded by white-space
identifier-list:
  identifier
  identifier-list , identifier
replacement-list:
  pp-tokensopt
pp-tokens:
  preprocessing-token
  pp-tokens preprocessing-token
new-line:
  the new-line character

```

- <sup>2</sup> A text line shall not begin with a # preprocessing token. A *conditionally-supported-directive* shall not begin with any of the directive names appearing in the syntax. A *conditionally-supported-directive* is conditionally-supported with implementation-defined semantics.
- <sup>3</sup> When in a group that is skipped (??), the directive syntax is relaxed to allow any sequence of preprocessing tokens to occur between the directive name and the following new-line character.
- <sup>4</sup> The only white-space characters that shall appear between preprocessing tokens within a preprocessing directive (from just after the introducing # preprocessing token through just before the terminating new-line character) are space and horizontal-tab (including spaces that have replaced comments or possibly other white-space characters in translation phase 3).
- <sup>5</sup> The implementation can process and skip sections of source files conditionally, include other source files, and replace macros. These capabilities are called *preprocessing*, because conceptually they occur before translation of the resulting translation unit.
- <sup>6</sup> The preprocessing tokens within a preprocessing directive are not subject to macro expansion unless otherwise stated.

[ *Example:* In:

```
#define EMPTY
EMPTY  #  include <file.h>
```

the sequence of preprocessing tokens on the second line is *not* a preprocessing directive, because it does not begin with a # at the start of translation phase 4, even though it will do so after the macro EMPTY has been replaced. — *end example* ]

## 19.1 Conditional inclusion

[cpp.cond]

*defined-macro-expression:*

```
defined identifier
defined ( identifier )
```

*h-preprocessing-token:*

```
any preprocessing-token other than >
```

*h-pp-tokens:*

```
h-preprocessing-token
h-pp-tokens h-preprocessing-token
```

*has-include-expression:*

```
--has_include ( < h-char-sequence > )
--has_include ( " q-char-sequence " )
--has_include ( string-literal )
--has_include ( < h-pp-tokens > )
```

- <sup>1</sup> The expression that controls conditional inclusion shall be an integral constant expression except that identifiers (including those lexically identical to keywords) are interpreted as described below<sup>148</sup> and it may contain zero or more *defined-macro-expressions* and/or *has-include-expressions* as unary operator expressions.
- <sup>2</sup> A *defined-macro-expression* evaluates to 1 if the identifier is currently defined as a macro name (that is, if it is predefined or if it has been the subject of a `#define` preprocessing directive without an intervening `#undef` directive with the same subject identifier), 0 if it is not.
- <sup>3</sup> The third and fourth forms of *has-include-expression* are considered only if neither of the first or second forms matches, in which case the preprocessing tokens are processed just as in normal text.
- <sup>4</sup> The header or source file identified by the parenthesized preprocessing token sequence in each contained *has-include-expression* is searched for as if that preprocessing token sequence were the *pp-tokens* in a `#include` directive, except that no further macro expansion is performed. If such a directive would not satisfy the syntactic requirements of a `#include` directive, the program is ill-formed. The *has-include-expression* evaluates to 1 if the search for the source file succeeds, and to 0 if the search fails.
- <sup>5</sup> The `#ifdef` and `#ifndef` directives, and the `defined` conditional inclusion operator, shall treat `--has_include` as if it were the name of a defined macro. The identifier `--has_include` shall not appear in any context not mentioned in this subclause.
- <sup>6</sup> Each preprocessing token that remains (in the list of preprocessing tokens that will become the controlling expression) after all macro replacements have occurred shall be in the lexical form of a token (??).
- <sup>7</sup> Preprocessing directives of the forms

```
# if      constant-expression new-line groupopt
# elif    constant-expression new-line groupopt
```

check whether the controlling constant expression evaluates to nonzero.

- <sup>8</sup> Prior to evaluation, macro invocations in the list of preprocessing tokens that will become the controlling constant expression are replaced (except for those macro names modified by the `defined` unary operator), just as in normal text. If the token `defined` is generated as a result of this replacement process or use of the `defined` unary operator does not match one of the two specified forms prior to macro replacement, the behavior is undefined.

---

<sup>148</sup>) Because the controlling constant expression is evaluated during translation phase 4, all identifiers either are or are not macro names — there simply are no keywords, enumeration constants, etc.

- <sup>9</sup> After all replacements due to macro expansion and evaluations of *defined-macro-expressions* and *has-include-expressions* have been performed, all remaining identifiers and keywords, except for `true` and `false`, are replaced with the *pp-number* 0, and then each preprocessing token is converted into a token. [ *Note*: An alternative token (??) is not an identifier, even when its spelling consists entirely of letters and underscores. Therefore it is not subject to this replacement. — *end note* ]
- <sup>10</sup> The resulting tokens comprise the controlling constant expression which is evaluated according to the rules of ?? using arithmetic that has at least the ranges specified in ???. For the purposes of this token conversion and evaluation all signed and unsigned integer types act as if they have the same representation as, respectively, `intmax_t` or `uintmax_t` (??). [ *Note*: Thus on an implementation where `std::numeric_limits<int>::max()` is 0x7FFF and `std::numeric_limits<unsigned int>::max()` is 0xFFFF, the integer literal 0x8000 is signed and positive within a `#if` expression even though it is unsigned in translation phase 7 (??). — *end note* ] This includes interpreting character literals, which may involve converting escape sequences into execution character set members. Whether the numeric value for these character literals matches the value obtained when an identical character literal occurs in an expression (other than within a `#if` or `#elif` directive) is implementation-defined. [ *Note*: Thus, the constant expression in the following `#if` directive and `if` statement is not guaranteed to evaluate to the same value in these two contexts:

```
#if 'z' - 'a' == 25
if ('z' - 'a' == 25)
```

— *end note*] Also, whether a single-character character literal may have a negative value is implementation-defined. Each subexpression with type `bool` is subjected to integral promotion before processing continues.

- <sup>11</sup> Preprocessing directives of the forms

```
# ifdef    identifier new-line groupopt
# ifndef   identifier new-line groupopt
```

check whether the identifier is or is not currently defined as a macro name. Their conditions are equivalent to `#if defined identifier` and `#if !defined identifier` respectively.

- <sup>12</sup> Each directive's condition is checked in order. If it evaluates to false (zero), the group that it controls is skipped: directives are processed only through the name that determines the directive in order to keep track of the level of nested conditionals; the rest of the directives' preprocessing tokens are ignored, as are the other preprocessing tokens in the group. Only the first group whose control condition evaluates to true (nonzero) is processed; any following groups are skipped and their controlling directives are processed as if they were in a group that is skipped. If none of the conditions evaluates to true, and there is a `#else` directive, the group controlled by the `#else` is processed; lacking a `#else` directive, all the groups until the `#endif` are skipped.<sup>149</sup>

[ *Example*: This demonstrates a way to include a library `optional` facility only if it is available:

```
#if __has_include(<optional>)
# include <optional>
# define have_optional 1
#elif __has_include(<experimental/optional>)
# include <experimental/optional>
# define have_optional 1
# define experimental_optional 1
#else
```

<sup>149</sup>) As indicated by the syntax, a preprocessing token shall not follow a `#else` or `#endif` directive before the terminating new-line character. However, comments may appear anywhere in a source file, including within a preprocessing directive.

```
# define have_optional 0
#endif
— end example ]
```

## 19.2 Source file inclusion

[**cpp.include**]

- <sup>1</sup> A `#include` directive shall identify a header or source file that can be processed by the implementation.
- <sup>2</sup> A preprocessing directive of the form

```
# include < h-char-sequence > new-line
```

searches a sequence of implementation-defined places for a header identified uniquely by the specified sequence between the `<` and `>` delimiters, and causes the replacement of that directive by the entire contents of the header. How the places are specified or the header identified is implementation-defined.

- <sup>3</sup> A preprocessing directive of the form

```
# include " q-char-sequence " new-line
```

causes the replacement of that directive by the entire contents of the source file identified by the specified sequence between the `"` delimiters. The named source file is searched for in an implementation-defined manner. If this search is not supported, or if the search fails, the directive is reprocessed as if it read

```
# include < h-char-sequence > new-line
```

with the identical contained sequence (including `>` characters, if any) from the original directive.

- <sup>4</sup> A preprocessing directive of the form

```
# include pp-tokens new-line
```

(that does not match one of the two previous forms) is permitted. The preprocessing tokens after `include` in the directive are processed just as in normal text (i.e., each identifier currently defined as a macro name is replaced by its replacement list of preprocessing tokens). If the directive resulting after all replacements does not match one of the two previous forms, the behavior is undefined.<sup>150</sup> The method by which a sequence of preprocessing tokens between a `<` and a `>` preprocessing token pair or a pair of `"` characters is combined into a single header name preprocessing token is implementation-defined.

- <sup>5</sup> The implementation shall provide unique mappings for sequences consisting of one or more *nondigits* or *digits* (??) followed by a period (.) and a single *nondigit*. The first character shall not be a *digit*. The implementation may ignore distinctions of alphabetical case.
- <sup>6</sup> A `#include` preprocessing directive may appear in a source file that has been read because of a `#include` directive in another file, up to an implementation-defined nesting limit.
- <sup>7</sup> [ *Note*: Although an implementation may provide a mechanism for making arbitrary source files available to the `<` `>` search, in general programmers should use the `<` `>` form for headers provided with the implementation, and the `"` `"` form for sources outside the control of the implementation. For instance:

```
#include <stdio.h>
#include <unistd.h>
#include "usefullib.h"
#include "myprog.h"
```

— end note ]

- <sup>8</sup> [ *Example*: This illustrates macro-replaced `#include` directives:

---

<sup>150</sup>) Note that adjacent string literals are not concatenated into a single string literal (see the translation phases in ??); thus, an expansion that results in two string literals is an invalid directive.

```

#ifndef VERSION == 1
    #define INCFILE "vers1.h"
#elif VERSION == 2
    #define INCFILE "vers2.h" // and so on
#else
    #define INCFILE "versN.h"
#endif
#include INCFILE
— end example]

```

### 19.3 Macro replacement

[cpp.replace]

- <sup>1</sup> Two replacement lists are identical if and only if the preprocessing tokens in both have the same number, ordering, spelling, and white-space separation, where all white-space separations are considered identical.
- <sup>2</sup> An identifier currently defined as an object-like macro (see below) may be redefined by another `#define` preprocessing directive provided that the second definition is an object-like macro definition and the two replacement lists are identical, otherwise the program is ill-formed. Likewise, an identifier currently defined as a function-like macro (see below) may be redefined by another `#define` preprocessing directive provided that the second definition is a function-like macro definition that has the same number and spelling of parameters, and the two replacement lists are identical, otherwise the program is ill-formed.
- <sup>3</sup> There shall be white-space between the identifier and the replacement list in the definition of an object-like macro.
- <sup>4</sup> If the *identifier-list* in the macro definition does not end with an ellipsis, the number of arguments (including those arguments consisting of no preprocessing tokens) in an invocation of a function-like macro shall equal the number of parameters in the macro definition. Otherwise, there shall be at least as many arguments in the invocation as there are parameters in the macro definition (excluding the ...). There shall exist a preprocessing token that terminates the invocation.
- <sup>5</sup> The identifiers `__VA_ARGS__` and `__VA_OPT__` shall occur only in the *replacement-list* of a function-like macro that uses the ellipsis notation in the parameters.
- <sup>6</sup> A parameter identifier in a function-like macro shall be uniquely declared within its scope.
- <sup>7</sup> The identifier immediately following the `define` is called the *macro name*. There is one name space for macro names. Any white-space characters preceding or following the replacement list of preprocessing tokens are not considered part of the replacement list for either form of macro.
- <sup>8</sup> If a `#` preprocessing token, followed by an identifier, occurs lexically at the point at which a preprocessing directive could begin, the identifier is not subject to macro replacement.
- <sup>9</sup> A preprocessing directive of the form

```
# define identifier replacement-list new-line
```

defines an *object-like macro* that causes each subsequent instance of the macro name<sup>151</sup> to be replaced by the replacement list of preprocessing tokens that constitute the remainder of the directive.<sup>152</sup> The replacement list is then rescanned for more macro names as specified below.

- <sup>10</sup> A preprocessing directive of the form

---

<sup>151</sup>) Since, by macro-replacement time, all character literals and string literals are preprocessing tokens, not sequences possibly containing identifier-like subsequences (see ??, translation phases), they are never scanned for macro names or parameters.

<sup>152</sup>) An alternative token (??) is not an identifier, even when its spelling consists entirely of letters and underscores. Therefore it is not possible to define a macro whose name is the same as that of an alternative token.

```
# define identifier lparen identifier-listopt ) replacement-list new-line
# define identifier lparen ... ) replacement-list new-line
# define identifier lparen identifier-list , ... ) replacement-list new-line
```

defines a *function-like macro* with parameters, whose use is similar syntactically to a function call. The parameters are specified by the optional list of identifiers, whose scope extends from their declaration in the identifier list until the new-line character that terminates the `#define` preprocessing directive. Each subsequent instance of the function-like macro name followed by a `(` as the next preprocessing token introduces the sequence of preprocessing tokens that is replaced by the replacement list in the definition (an invocation of the macro). The replaced sequence of preprocessing tokens is terminated by the matching `)` preprocessing token, skipping intervening matched pairs of left and right parenthesis preprocessing tokens. Within the sequence of preprocessing tokens making up an invocation of a function-like macro, new-line is considered a normal white-space character.

- <sup>11</sup> The sequence of preprocessing tokens bounded by the outside-most matching parentheses forms the list of arguments for the function-like macro. The individual arguments within the list are separated by comma preprocessing tokens, but comma preprocessing tokens between matching inner parentheses do not separate arguments. If there are sequences of preprocessing tokens within the list of arguments that would otherwise act as preprocessing directives,<sup>153</sup> the behavior is undefined.
- <sup>12</sup> If there is a `...` immediately preceding the `)` in the function-like macro definition, then the trailing arguments (if any), including any separating comma preprocessing tokens, are merged to form a single item: the *variable arguments*. The number of arguments so combined is such that, following merger, the number of arguments is either equal to or one more than the number of parameters in the macro definition (excluding the `...`).

### 19.3.1 Argument substitution

[cpp.subst]

- <sup>1</sup> After the arguments for the invocation of a function-like macro have been identified, argument substitution takes place. A parameter in the replacement list, unless preceded by a `#` or `##` preprocessing token or followed by a `##` preprocessing token (see below), is replaced by the corresponding argument after all macros contained therein have been expanded. Before being substituted, each argument's preprocessing tokens are completely macro replaced as if they formed the rest of the preprocessing file; no other preprocessing tokens are available.
- <sup>2</sup> An identifier `__VA_ARGS__` that occurs in the replacement list shall be treated as if it were a parameter, and the variable arguments shall form the preprocessing tokens used to replace it.
- <sup>3</sup> The identifier `__VA_OPT__` shall always occur as part of the token sequence `__VA_OPT__(content)`, where *content* is an arbitrary sequence of *preprocessing-tokens* other than `__VA_OPT__`, which is terminated by the closing `)` and skips intervening pairs of matching left and right parentheses. If *content* would be ill-formed as the replacement list of the current function-like macro, the program is ill-formed. The token sequence `__VA_OPT__(content)` shall be treated as if it were a parameter, and the preprocessing tokens used to replace it are defined as follows. If the variable arguments consist of no tokens, the replacement consists of a single placemarker preprocessing token (`??, ??`). Otherwise, the replacement consists of the results of the expansion of *content* as the replacement list of the current function-like macro before rescanning and further replacement.

[Example:

```
#define F(...)          f(0 __VA_OPT__(,) __VA_ARGS__)
#define G(X, ...)        f(0, X __VA_OPT__(,) __VA_ARGS__)
#define SDEF(sname, ...)  S sname __VA_OPT__(= { __VA_ARGS__ })
```

---

<sup>153</sup>) A *conditionally-supported-directive* is a preprocessing directive regardless of whether the implementation supports it.

```

F(a, b, c)      // replaced by f(0, a, b, c)
F()             // replaced by f(0)

G(a, b, c)      // replaced by f(0, a, b, c)
G(a, )          // replaced by f(0, a)
G(a)            // replaced by f(0, a)

SDEF(foo);      // replaced by S foo;
SDEF(bar, 1, 2); // replaced by S bar = { 1, 2 };

#define H1(X, ...) X __VA_OPT__(##) __VA_ARGS__ // ill-formed: ## may not appear at
  // the beginning of a replacement list (??)
#define H2(X, Y, ...) __VA_OPT__(X ## Y,) __VA_ARGS__

H2(a, b, c, d) // replaced by ab, c, d
— end example]

```

### 19.3.2 The # operator

[cpp.stringize]

- <sup>1</sup> Each # preprocessing token in the replacement list for a function-like macro shall be followed by a parameter as the next preprocessing token in the replacement list.
- <sup>2</sup> A *character string literal* is a *string-literal* with no prefix. If, in the replacement list, a parameter is immediately preceded by a # preprocessing token, both are replaced by a single character string literal preprocessing token that contains the spelling of the preprocessing token sequence for the corresponding argument. Each occurrence of white space between the argument's preprocessing tokens becomes a single space character in the character string literal. White space before the first preprocessing token and after the last preprocessing token comprising the argument is deleted. Otherwise, the original spelling of each preprocessing token in the argument is retained in the character string literal, except for special handling for producing the spelling of string literals and character literals: a \ character is inserted before each " and \ character of a character literal or string literal (including the delimiting " characters). If the replacement that results is not a valid character string literal, the behavior is undefined. The character string literal corresponding to an empty argument is "". The order of evaluation of # and ## operators is unspecified.

### 19.3.3 The ## operator

[cpp.concat]

- <sup>1</sup> A ## preprocessing token shall not occur at the beginning or at the end of a replacement list for either form of macro definition.
- <sup>2</sup> If, in the replacement list of a function-like macro, a parameter is immediately preceded or followed by a ## preprocessing token, the parameter is replaced by the corresponding argument's preprocessing token sequence; however, if an argument consists of no preprocessing tokens, the parameter is replaced by a placemarker preprocessing token instead.<sup>154</sup>
- <sup>3</sup> For both object-like and function-like macro invocations, before the replacement list is reexamined for more macro names to replace, each instance of a ## preprocessing token in the replacement list (not from an argument) is deleted and the preceding preprocessing token is concatenated with the following preprocessing token. Placemarker preprocessing tokens are handled specially: concatenation of two placemarkers results in a single placemarker preprocessing token, and concatenation of a placemarker with a non-placemarker

<sup>154)</sup> Placemarker preprocessing tokens do not appear in the syntax because they are temporary entities that exist only within translation phase 4.

preprocessing token results in the non-placemarker preprocessing token. If the result is not a valid preprocessing token, the behavior is undefined. The resulting token is available for further macro replacement. The order of evaluation of `##` operators is unspecified.

[*Example*: In the following fragment:

```
#define hash_hash # ## #
#define mkstr(a) # a
#define in_between(a) mkstr(a)
#define join(c, d) in_between(c hash_hash d)
char p[] = join(x, y);           // equivalent to char p[] = "x ## y";
```

The expansion produces, at various stages:

```
join(x, y)
in_between(x hash_hash y)
in_between(x ## y)
mkstr(x ## y)
"x ## y"
```

In other words, expanding `hash_hash` produces a new token, consisting of two adjacent sharp signs, but this new token is not the `##` operator. — *end example*]

### 19.3.4 Rescanning and further replacement

[**cpp.rescan**]

- <sup>1</sup> After all parameters in the replacement list have been substituted and `#` and `##` processing has taken place, all placemarker preprocessing tokens are removed. Then the resulting preprocessing token sequence is rescanned, along with all subsequent preprocessing tokens of the source file, for more macro names to replace.
- <sup>2</sup> If the name of the macro being replaced is found during this scan of the replacement list (not including the rest of the source file's preprocessing tokens), it is not replaced. Furthermore, if any nested replacements encounter the name of the macro being replaced, it is not replaced. These nonreplaced macro name preprocessing tokens are no longer available for further replacement even if they are later (re)examined in contexts in which that macro name preprocessing token would otherwise have been replaced.
- <sup>3</sup> The resulting completely macro-replaced preprocessing token sequence is not processed as a preprocessing directive even if it resembles one, but all pragma unary operator expressions within it are then processed as specified in ?? below.

### 19.3.5 Scope of macro definitions

[**cpp.scope**]

- <sup>1</sup> A macro definition lasts (independent of block structure) until a corresponding `#undef` directive is encountered or (if none is encountered) until the end of the translation unit. Macro definitions have no significance after translation phase 4.
- <sup>2</sup> A preprocessing directive of the form

```
# undef identifier new-line
```

causes the specified identifier no longer to be defined as a macro name. It is ignored if the specified identifier is not currently defined as a macro name.

- <sup>3</sup> [*Example*: The simplest use of this facility is to define a “manifest constant”, as in

```
#define TABSIZE 100
int table[TABSIZE];
— end example
```

- <sup>4</sup> [ *Example:* The following defines a function-like macro whose value is the maximum of its arguments. It has the advantages of working for any compatible types of the arguments and of generating in-line code without the overhead of function calling. It has the disadvantages of evaluating one or the other of its arguments a second time (including side effects) and generating more code than a function if invoked several times. It also cannot have its address taken, as it has none.

```
#define max(a, b) ((a) > (b) ? (a) : (b))
```

The parentheses ensure that the arguments and the resulting expression are bound properly. — *end example* ]

- <sup>5</sup> [ *Example:* To illustrate the rules for redefinition and reexamination, the sequence

```
#define x      3
#define f(a)    f(x * (a))
#undef x
#define x      2
#define g      f
#define z      z[0]
#define h      g(~
#define m(a)  a(w)
#define w      0,1
#define t(a)  a
#define p()    int
#define q(x)  x
#define r(x,y) x ## y
#define str(x) # x

f(y+1) + f(f(z)) % t(t(g)(0) + t)(1);
g(x+(3,4)-w) | h 5) & m
(f)^m(m);
p() i[q()] = { q(1), r(2,3), r(4,), r(,5), r(,) };
char c[2][6] = { str(hello), str() };
```

results in

```
f(2 * (y+1)) + f(2 * (f(2 * (z[0])))) % f(2 * (0)) + t(1);
f(2 * (2+(3,4)-0,1)) | f(2 * (~ 5)) & f(2 * (0,1))^m(0,1);
int i[] = { 1, 23, 4, 5, };
char c[2][6] = { "hello", "" };
```

— *end example* ]

- <sup>6</sup> [ *Example:* To illustrate the rules for creating character string literals and concatenating tokens, the sequence

```
#define str(s)      # s
#define xstr(s)     str(s)
#define debug(s, t) printf("x" # s "= %d, x" # t "= %s", \
                      x ## s, x ## t)
#define INCFILE(n)   vers ## n
#define glue(a, b)   a ## b
#define xglue(a, b) glue(a, b)
#define HIGHLOW     "hello"
#define LOW         LOW ", world"

debug(1, 2);
```

```
fputs(str(strncmp("abc\0d", "abc", '\4')           // this goes away
        == 0) str(: @\n), s);
#include xstr(INCFILE(2).h)
glue(HIGH, LOW);
xglue(HIGH, LOW)
```

results in

```
printf("x" "1" "= %d, x" "2" "= %s", x1, x2);
fputs("strcmp(\"abc\\0d\", \"abc\", '\\4') == 0" ": @\n", s);
#include "vers2.h"      (after macro replacement, before file access)
"hello";
"hello" ", world"
```

or, after concatenation of the character string literals,

```
printf("x1= %d, x2= %s", x1, x2);
fputs("strcmp(\"abc\\0d\", \"abc\", '\\4') == 0: @\n", s);
#include "vers2.h"      (after macro replacement, before file access)
"hello";
"hello, world"
```

Space around the # and ## tokens in the macro definition is optional. — end example]

- 7 [Example: To illustrate the rules for placemarker preprocessing tokens, the sequence

```
#define t(x,y,z) x ## y ## z
int j[] = { t(1,2,3), t(,4,5), t(6,,7), t(8,9,,,
t(10,,,), t(,11,,), t(,,12), t(,,) };
```

results in

```
int j[] = { 123, 45, 67, 89,
10, 11, 12, };
```

— end example]

- 8 [Example: To demonstrate the redefinition rules, the following sequence is valid.

```
#define OBJ_LIKE      (1-1)
#define OBJ_LIKE      /* white space */ (1-1) /* other */
#define FUNC_LIKE(a)   ( a )
#define FUNC_LIKE( a )( /* note the white space */ \
a /* other stuff on this line
*)
```

But the following redefinitions are invalid:

```
#define OBJ_LIKE      (0)          // different token sequence
#define OBJ_LIKE      (1 - 1)       // different white space
#define FUNC_LIKE(b)   ( a )        // different parameter usage
#define FUNC_LIKE(b)   ( b )        // different parameter spelling
```

— end example]

- 9 [Example: Finally, to show the variable argument list macro facilities:

```
#define debug(...) fprintf(stderr, __VA_ARGS__)
#define showlist(...) puts(__VA_ARGS__)
#define report(test, ...) ((test) ? puts(#test) : printf(__VA_ARGS__))
debug("Flag");
```

```
debug("X = %d\n", x);
showlist(The first, second, and third items.);
report(x>y, "x is %d but y is %d", x, y);
```

results in

```
fprintf(stderr, "Flag");
fprintf(stderr, "X = %d\n", x);
puts("The first, second, and third items.");
((x>y) ? puts("x>y") : printf("x is %d but y is %d", x, y));
— end example]
```

## 19.4 Line control

[cpp.line]

- <sup>1</sup> The string literal of a `#line` directive, if present, shall be a character string literal.
- <sup>2</sup> The *line number* of the current source line is one greater than the number of new-line characters read or introduced in translation phase 1 (??) while processing the source file to the current token.
- <sup>3</sup> A preprocessing directive of the form

```
# line digit-sequence new-line
```

causes the implementation to behave as if the following sequence of source lines begins with a source line that has a line number as specified by the digit sequence (interpreted as a decimal integer). If the digit sequence specifies zero or a number greater than 2147483647, the behavior is undefined.

- <sup>4</sup> A preprocessing directive of the form

```
# line digit-sequence " s-char-sequenceopt " new-line
```

sets the presumed line number similarly and changes the presumed name of the source file to be the contents of the character string literal.

- <sup>5</sup> A preprocessing directive of the form

```
# line pp-tokens new-line
```

(that does not match one of the two previous forms) is permitted. The preprocessing tokens after `line` on the directive are processed just as in normal text (each identifier currently defined as a macro name is replaced by its replacement list of preprocessing tokens). If the directive resulting after all replacements does not match one of the two previous forms, the behavior is undefined; otherwise, the result is processed as appropriate.

## 19.5 Error directive

[cpp.error]

- <sup>1</sup> A preprocessing directive of the form

```
# error pp-tokensopt new-line
```

causes the implementation to produce a diagnostic message that includes the specified sequence of preprocessing tokens, and renders the program ill-formed.

## 19.6 Pragma directive

[cpp.pragma]

- <sup>1</sup> A preprocessing directive of the form

```
# pragma pp-tokensopt new-line
```

causes the implementation to behave in an implementation-defined manner. The behavior might cause translation to fail or cause the translator or the resulting program to behave in a non-conforming manner. Any pragma that is not recognized by the implementation is ignored.

## 19.7 Null directive

[cpp.null]

- <sup>1</sup> A preprocessing directive of the form

```
# new-line
```

has no effect.

## 19.8 Predefined macro names

[cpp.predefined]

- <sup>1</sup> The following macro names shall be defined by the implementation:

`--cplusplus`

The integer literal 201703L.<sup>155</sup>

`--DATE--`

The date of translation of the source file: a character string literal of the form "Mmm dd yyyy", where the names of the months are the same as those generated by the `asctime` function, and the first character of dd is a space character if the value is less than 10. If the date of translation is not available, an implementation-defined valid date shall be supplied.

`--FILE--`

The presumed name of the current source file (a character string literal).<sup>156</sup>

`--LINE--`

The presumed line number (within the current source file) of the current source line (an integer literal).<sup>157</sup>

`--STDC_HOSTED--`

The integer literal 1 if the implementation is a hosted implementation or the integer literal 0 if it is not.

`--STDCPP_DEFAULT_ALIGNMENT--`

An integer literal of type `std::size_t` whose value is the alignment guaranteed by a call to `operator new(std::size_t)` or `operator new[](std::size_t)`. [Note: Larger alignments will be passed to `operator new(std::size_t, std::align_val_t)`, etc. (??). —end note]

`--TIME--`

The time of translation of the source file: a character string literal of the form "hh:mm:ss" as in the time generated by the `asctime` function. If the time of translation is not available, an implementation-defined valid time shall be supplied.

- <sup>2</sup> The following macro names are conditionally defined by the implementation:

`--STDC--`

Whether `--STDC--` is predefined and if so, what its value is, are implementation-defined.

`--STDC_MB_MIGHT_NEQ_WC--`

The integer literal 1, intended to indicate that, in the encoding for `wchar_t`, a member of the basic character set need not have a code value equal to its value when used as the lone character in an ordinary character literal.

<sup>155</sup>) It is intended that future versions of this International Standard will replace the value of this macro with a greater value. Non-conforming compilers should use a value with at most five decimal digits.

<sup>156</sup>) The presumed source file name can be changed by the `#line` directive.

<sup>157</sup>) The presumed line number can be changed by the `#line` directive.

**`--STDC_VERSION--`**

Whether `--STDC_VERSION--` is predefined and if so, what its value is, are implementation-defined.

**`--STDC_ISO_10646--`**

An integer literal of the form `yyyymmL` (for example, `199712L`). If this symbol is defined, then every character in the Unicode required set, when stored in an object of type `wchar_t`, has the same value as the short identifier of that character. The *Unicode required set* consists of all the characters that are defined by ISO/IEC 10646, along with all amendments and technical corrigenda as of the specified year and month.

**`--STDCPP_STRICT_POINTER_SAFETY--`**

Defined, and has the value integer literal 1, if and only if the implementation has strict pointer safety (??).

**`--STDCPP_THREADS--`**

Defined, and has the value integer literal 1, if and only if a program can have more than one thread of execution (??).

<sup>3</sup> The values of the predefined macros (except for `--FILE--` and `--LINE--`) remain constant throughout the translation unit.

<sup>4</sup> If any of the pre-defined macro names in this subclause, or the identifier `defined`, is the subject of a `#define` or a `#undef` preprocessing directive, the behavior is undefined. Any other predefined macro names shall begin with a leading underscore followed by an uppercase letter or a second underscore.

## 19.9 Pragma operator

[[cpp.pragma.op](#)]

<sup>1</sup> A unary operator expression of the form:

`_Pragma ( string-literal )`

is processed as follows: The string literal is *destringized* by deleting the L prefix, if present, deleting the leading and trailing double-quotes, replacing each escape sequence `\"` by a double-quote, and replacing each escape sequence `\\"` by a single backslash. The resulting sequence of characters is processed through translation phase 3 to produce preprocessing tokens that are executed as if they were the *pp-tokens* in a pragma directive. The original four preprocessing tokens in the unary operator expression are removed.

<sup>2</sup> [*Example*:

`#pragma listing on "..\listing.dir"`

can also be expressed as:

`_Pragma ( "listing on \"..\\"listing.dir\\\" " )`

The latter form is processed in the same way whether it appears literally as shown, or results from macro replacement, as in:

```
#define LISTING(x) PRAGMA(listing on #x)
#define PRAGMA(x) _Pragma(#x)
```

`LISTING( ..\listing.dir )`

— *end example*]

# 20 Library introduction

[library]

## 20.1 General

[library.general]

- <sup>1</sup> This Clause describes the contents of the *C++ standard library*, how a well-formed C++ program makes use of the library, and how a conforming implementation may provide the entities in the library.
- <sup>2</sup> The following subclauses describe the definitions (??), method of description (??), and organization (??) of the library. ??, ?? through ??, and ?? specify the contents of the library, as well as library requirements and constraints on both well-formed C++ programs and conforming implementations.
- <sup>3</sup> Detailed specifications for each of the components in the library are in ??–??, as shown in Table ??.

Table 15 — Library categories

| Clause | Category                    |
|--------|-----------------------------|
| ??     | Language support library    |
| ??     | Diagnostics library         |
| ??     | General utilities library   |
| ??     | Strings library             |
| ??     | Localization library        |
| ??     | Containers library          |
| ??     | Iterators library           |
| ??     | Algorithms library          |
| ??     | Numerics library            |
| ??     | Input/output library        |
| ??     | Regular expressions library |
| ??     | Atomic operations library   |
| ??     | Thread support library      |

- <sup>4</sup> The language support library (??) provides components that are required by certain parts of the C++ language, such as memory allocation (??, ??) and exception processing (??).
- <sup>5</sup> The diagnostics library (??) provides a consistent framework for reporting errors in a C++ program, including predefined exception classes.
- <sup>6</sup> The general utilities library (??) includes components used by other library elements, such as a predefined storage allocator for dynamic storage management (??), and components used as infrastructure in C++ programs, such as tuples, function wrappers, and time facilities.
- <sup>7</sup> The strings library (??) provides support for manipulating text represented as sequences of type `char`, sequences of type `char16_t`, sequences of type `char32_t`, sequences of type `wchar_t`, and sequences of any other character-like type.
- <sup>8</sup> The localization library (??) provides extended internationalization support for text processing.
- <sup>9</sup> The containers (??), iterators (??), and algorithms (??) libraries provide a C++ program with access to a subset of the most widely used algorithms and data structures.
- <sup>10</sup> The numerics library (??) provides numeric algorithms and complex number components that extend support for numeric processing. The `valarray` component provides support for *n*-at-a-time processing, potentially implemented as parallel operations on platforms that support such processing. The random number component provides facilities for generating pseudo-random numbers.

- <sup>11</sup> The input/output library (??) provides the `iostream` components that are the primary mechanism for C++ program input and output. They can be used with other elements of the library, particularly strings, locales, and iterators.
- <sup>12</sup> The regular expressions library (??) provides regular expression matching and searching.
- <sup>13</sup> The atomic operations library (??) allows more fine-grained concurrent access to shared data than is possible with locks.
- <sup>14</sup> The thread support library (??) provides components to create and manage threads, including mutual exclusion and interthread communication.

## 20.2 The C standard library

[library.c]

- <sup>1</sup> The C++ standard library also makes available the facilities of the C standard library, suitably adjusted to ensure static type safety.
- <sup>2</sup> The descriptions of many library functions rely on the C standard library for the semantics of those functions. In some cases, the signatures specified in this document may be different from the signatures in the C standard library, and additional overloads may be declared in this document, but the behavior and the preconditions (including any preconditions implied by the use of an ISO C `restrict` qualifier) are the same unless otherwise stated.

## 20.3 Definitions

[definitions]

- <sup>1</sup> [ *Note:* ?? defines additional terms used elsewhere in this document. — end note ]

### 20.3.1

[defns.arbitrary.stream]

#### arbitrary-positional stream

stream (described in ??) that can seek to any integral position within the length of the stream

[ *Note 1 to entry:* Every arbitrary-positional stream is also a repositional stream. — end note ]

### 20.3.2

[defns.character]

#### character

⟨??, ??, ??, and ??⟩ object which, when treated sequentially, can represent text

[ *Note 1 to entry:* The term does not mean only `char`, `char16_t`, `char32_t`, and `wchar_t` objects, but any value that can be represented by a type that provides the definitions specified in these Clauses. — end note ]

### 20.3.3

[defns.character.container]

#### character container type

class or a type used to represent a character

[ *Note 1 to entry:* It is used for one of the template parameters of the string, iostream, and regular expression class templates. — end note ]

### 20.3.4

[defns.comparison]

#### comparison function

operator function (??) for any of the equality (??) or relational (??) operators

### 20.3.5

[defns.component]

#### component

group of library entities directly related as members, parameters, or return types

[*Note 1 to entry:* For example, the class template `basic_string` and the non-member function templates that operate on strings are referred to as the *string component*. — *end note*]

**20.3.6**[`defns.const.subexpr`]**constant subexpression**

expression whose evaluation as subexpression of a *conditional-expression* CE (??) would not prevent CE from being a core constant expression (??)

**20.3.7**[`defns.deadlock`]**deadlock**

situation wherein one or more threads are unable to continue execution because each is blocked waiting for one or more of the others to satisfy some condition

**20.3.8**[`defns.default.behavior.impl`]**default behavior**

*(implementation)* specific behavior provided by the implementation, within the scope of the *required behavior*

**20.3.9**[`defns.default.behavior.func`]**default behavior**

*(specification)* description of *replacement function* and *handler function* semantics

**20.3.10**[`defns.direct-non-list-init`]**direct-non-list-initialization**

direct-initialization (??) that is not list-initialization (??)

**20.3.11**[`defns.handler`]**handler function**

*non-reserved function* whose definition may be provided by a C++ program

[*Note 1 to entry:* A C++ program may designate a handler function at various points in its execution by supplying a pointer to the function when calling any of the library functions that install handler functions (??). — *end note*]

**20.3.12**[`defns.iofstream.templates`]**iostream class templates**

templates, defined in ??, that take two template arguments

[*Note 1 to entry:* The arguments are named `charT` and `traits`. The argument `charT` is a character container class, and the argument `traits` is a class which defines additional characteristics and functions of the character type represented by `charT` necessary to implement the iostream class templates. — *end note*]

**20.3.13**[`defns.modifier`]**modifier function**

class member function (??) other than a constructor, assignment operator, or destructor that alters the state of an object of the class

**20.3.14**[`defns.move.assign`]**move assignment**

assignment of an rvalue of some object type to a modifiable lvalue of the same type

|                                                                                                                                                                                                                                                         |                                      |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------|
| <b>20.3.15</b>                                                                                                                                                                                                                                          | [ <b>defns.move.constr</b> ]         |
| <b>move construction</b>                                                                                                                                                                                                                                |                                      |
| direct-initialization of an object of some type with an rvalue of the same type                                                                                                                                                                         |                                      |
| <b>20.3.16</b>                                                                                                                                                                                                                                          | [ <b>defns.ntcts</b> ]               |
| <b>NTCTS</b>                                                                                                                                                                                                                                            |                                      |
| sequence of values that have character type that precede the terminating null character type value <code>charT()</code>                                                                                                                                 |                                      |
| <b>20.3.17</b>                                                                                                                                                                                                                                          | [ <b>defns.observer</b> ]            |
| <b>observer function</b>                                                                                                                                                                                                                                |                                      |
| class member function (??) that accesses the state of an object of the class but does not alter that state                                                                                                                                              |                                      |
| [ <i>Note 1 to entry:</i> Observer functions are specified as <code>const</code> member functions (??). — <i>end note</i> ]                                                                                                                             |                                      |
| <b>20.3.18</b>                                                                                                                                                                                                                                          | [ <b>defns.referenceable</b> ]       |
| <b>referenceable type</b>                                                                                                                                                                                                                               |                                      |
| type that is either an object type, a function type that does not have cv-qualifiers or a <i>ref-qualifier</i> , or a reference type                                                                                                                    |                                      |
| [ <i>Note 1 to entry:</i> The term describes a type to which a reference can be created, including reference types. — <i>end note</i> ]                                                                                                                 |                                      |
| <b>20.3.19</b>                                                                                                                                                                                                                                          | [ <b>defns.replacement</b> ]         |
| <b>replacement function</b>                                                                                                                                                                                                                             |                                      |
| non-reserved function whose definition is provided by a C++ program                                                                                                                                                                                     |                                      |
| [ <i>Note 1 to entry:</i> Only one definition for such a function is in effect for the duration of the program's execution, as the result of creating the program (??) and resolving the definitions of all translation units (??). — <i>end note</i> ] |                                      |
| <b>20.3.20</b>                                                                                                                                                                                                                                          | [ <b>defns.repositional.stream</b> ] |
| <b>repositional stream</b>                                                                                                                                                                                                                              |                                      |
| stream (described in ??) that can seek to a position that was previously encountered                                                                                                                                                                    |                                      |
| <b>20.3.21</b>                                                                                                                                                                                                                                          | [ <b>defns.required.behavior</b> ]   |
| <b>required behavior</b>                                                                                                                                                                                                                                |                                      |
| description of <i>replacement function</i> and <i>handler function</i> semantics applicable to both the behavior provided by the implementation and the behavior of any such function definition in the program                                         |                                      |
| [ <i>Note 1 to entry:</i> If such a function defined in a C++ program fails to meet the required behavior when it executes, the behavior is undefined. — <i>end note</i> ]                                                                              |                                      |
| <b>20.3.22</b>                                                                                                                                                                                                                                          | [ <b>defns.reserved.function</b> ]   |
| <b>reserved function</b>                                                                                                                                                                                                                                |                                      |
| function, specified as part of the C++ standard library, that is defined by the implementation                                                                                                                                                          |                                      |
| [ <i>Note 1 to entry:</i> If a C++ program provides a definition for any reserved function, the results are undefined. — <i>end note</i> ]                                                                                                              |                                      |

**20.3.23**[**defns.stable**]**stable algorithm**

algorithm that preserves, as appropriate to the particular algorithm, the order of elements

[*Note 1 to entry:* Requirements for stable algorithms are given in ???. — *end note*]

**20.3.24**[**defns.traits**]**traits class**

class that encapsulates a set of types and functions necessary for class templates and function templates to manipulate objects of types for which they are instantiated

**20.3.25**[**defns.valid**]**valid but unspecified state**

value of an object that is not specified except that the object's invariants are met and operations on the object behave as specified for its type

[*Example:* If an object `x` of type `std::vector<int>` is in a valid but unspecified state, `x.empty()` can be called unconditionally, and `x.front()` can be called only if `x.empty()` returns `false`. — *end example*]

**20.4 Method of description (Informative)**[**description**]

- <sup>1</sup> This subclause describes the conventions used to specify the C++ standard library. ?? describes the structure of the normative ?? through ?? and ???. ?? describes other editorial conventions.

**20.4.1 Structure of each clause**[**structure**]**20.4.1.1 Elements**[**structure.elements**]

- <sup>1</sup> Each library clause contains the following elements, as applicable:<sup>158</sup>

- (1.1) — Summary
- (1.2) — Requirements
- (1.3) — Detailed specifications
- (1.4) — References to the C standard library

**20.4.1.2 Summary**[**structure.summary**]

- <sup>1</sup> The Summary provides a synopsis of the category, and introduces the first-level subclauses. Each subclause also provides a summary, listing the headers specified in the subclause and the library entities provided in each header.
- <sup>2</sup> The contents of the summary and the detailed specifications include:

- (2.1) — macros
- (2.2) — values
- (2.3) — types
- (2.4) — classes and class templates
- (2.5) — functions and function templates
- (2.6) — objects

<sup>158</sup>) To save space, items that do not apply to a Clause are omitted. For example, if a Clause does not specify any requirements, there will be no “Requirements” subclause.

### 20.4.1.3 Requirements

[**structure.requirements**]

- <sup>1</sup> Requirements describe constraints that shall be met by a C++ program that extends the standard library. Such extensions are generally one of the following:
  - (1.1) — Template arguments
  - (1.2) — Derived classes
  - (1.3) — Containers, iterators, and algorithms that meet an interface convention
- <sup>2</sup> The string and iostream components use an explicit representation of operations required of template arguments. They use a class template `char_traits` to define these constraints.
- <sup>3</sup> Interface convention requirements are stated as generally as possible. Instead of stating “class X has to define a member function `operator++()`”, the interface requires “for any object x of class X, `++x` is defined”. That is, whether the operator is a member is unspecified.
- <sup>4</sup> Requirements are stated in terms of well-defined expressions that define valid terms of the types that satisfy the requirements. For every set of well-defined expression requirements there is a table that specifies an initial set of the valid expressions and their semantics. Any generic algorithm (??) that uses the well-defined expression requirements is described in terms of the valid expressions for its template type parameters.
- <sup>5</sup> Template argument requirements are sometimes referenced by name. See ??.
- <sup>6</sup> In some cases the semantic requirements are presented as C++ code. Such code is intended as a specification of equivalence of a construct to another construct, not necessarily as the way the construct must be implemented.<sup>159</sup>

### 20.4.1.4 Detailed specifications

[**structure.specifications**]

- <sup>1</sup> The detailed specifications each contain the following elements:

- (1.1) — name and brief description
- (1.2) — synopsis (class definition or function declaration, as appropriate)
- (1.3) — restrictions on template arguments, if any
- (1.4) — description of class invariants
- (1.5) — description of function semantics

- <sup>2</sup> Descriptions of class member functions follow the order (as appropriate):<sup>160</sup>

- (2.1) — constructor(s) and destructor
- (2.2) — copying, moving & assignment functions
- (2.3) — comparison functions
- (2.4) — modifier functions
- (2.5) — observer functions
- (2.6) — operators and other non-member functions

- <sup>3</sup> Descriptions of function semantics contain the following elements (as appropriate):<sup>161</sup>

- (3.1) — *Requires*: the preconditions for calling the function

<sup>159</sup>) Although in some cases the code given is unambiguously the optimum implementation.

<sup>160</sup>) To save space, items that do not apply to a class are omitted. For example, if a class does not specify any comparison functions, there will be no “Comparison functions” subclause.

<sup>161</sup>) To save space, items that do not apply to a function are omitted. For example, if a function does not specify any further preconditions, there will be no *Requires*: paragraph.

- (3.2) — *Effects*: the actions performed by the function
- (3.3) — *Synchronization*: the synchronization operations (??) applicable to the function
- (3.4) — *Postconditions*: the observable results established by the function
- (3.5) — *Returns*: a description of the value(s) returned by the function
- (3.6) — *Throws*: any exceptions thrown by the function, and the conditions that would cause the exception
- (3.7) — *Complexity*: the time and/or space complexity of the function
- (3.8) — *Remarks*: additional semantic constraints on the function
- (3.9) — *Error conditions*: the error conditions for error codes reported by the function

- <sup>4</sup> Whenever the *Effects* element specifies that the semantics of some function F are *Equivalent to* some code sequence, then the various elements are interpreted as follows. If F's semantics specifies a *Requires* element, then that requirement is logically imposed prior to the *equivalent-to* semantics. Next, the semantics of the code sequence are determined by the *Requires*, *Effects*, *Synchronization*, *Postconditions*, *Returns*, *Throws*, *Complexity*, *Remarks*, and *Error conditions* specified for the function invocations contained in the code sequence. The value returned from F is specified by F's *Returns* element, or if F has no *Returns* element, a non-`void` return from F is specified by the `return` statements in the code sequence. If F's semantics contains a *Throws*, *Postconditions*, or *Complexity* element, then that supersedes any occurrences of that element in the code sequence.
- <sup>5</sup> For non-reserved replacement and handler functions, ?? specifies two behaviors for the functions in question: their required and default behavior. The *default behavior* describes a function definition provided by the implementation. The *required behavior* describes the semantics of a function definition provided by either the implementation or a C++ program. Where no distinction is explicitly made in the description, the behavior described is the required behavior.
- <sup>6</sup> If the formulation of a complexity requirement calls for a negative number of operations, the actual requirement is zero operations.<sup>162</sup>
- <sup>7</sup> Complexity requirements specified in the library clauses are upper bounds, and implementations that provide better complexity guarantees satisfy the requirements.
- <sup>8</sup> Error conditions specify conditions where a function may fail. The conditions are listed, together with a suitable explanation, as the `enum class errc` constants (??).

#### 20.4.1.5 C library

[structure.see.also]

- <sup>1</sup> Paragraphs labeled “SEE ALSO” contain cross-references to the relevant portions of the ISO C standard.

#### 20.4.2 Other conventions

[conventions]

- <sup>1</sup> This subclause describes several editorial conventions used to describe the contents of the C++ standard library. These conventions are for describing implementation-defined types (??), and member functions (??).

##### 20.4.2.1 Type descriptions

[type.descriptions]

###### 20.4.2.1.1 General

[type.descriptions.general]

- <sup>1</sup> The Requirements subclauses may describe names that are used to specify constraints on template arguments.<sup>163</sup> These names are used in library Clauses to describe the types that may be supplied as arguments

<sup>162)</sup> This simplifies the presentation of complexity requirements in some cases.

<sup>163)</sup> Examples from ?? include: `EqualityComparable`, `LessThanComparable`, `CopyConstructible`. Examples from ?? include: `InputIterator`, `ForwardIterator`.

by a C++ program when instantiating template components from the library.

- 2 Certain types defined in ?? are used to describe implementation-defined types. They are based on other types, but with added constraints.

#### 20.4.2.1.2 Exposition-only types

[expos.only.types]

- 1 Several types defined in ?? through ?? and ?? that are used as function parameter or return types are defined for the purpose of exposition only in order to capture their language linkage. The declarations of such types are followed by a comment ending in *exposition only*. [Example:

```
namespace std {
    extern "C" using some-handler = int(int, void*, double); // exposition only
}
```

The type placeholder *some-handler* can now be used to specify a function that takes a callback parameter with C language linkage. —end example]

#### 20.4.2.1.3 Enumerated types

[enumerated.types]

- 1 Several types defined in ?? are *enumerated types*. Each enumerated type may be implemented as an enumeration or as a synonym for an enumeration.<sup>164</sup>
- 2 The enumerated type *enumerated* can be written:

```
enum enumerated { V0, V1, V2, V3, ..... };
```

```
inline const enumerated C0(V0);
inline const enumerated C1(V1);
inline const enumerated C2(V2);
inline const enumerated C3(V3);
....
```

- 3 Here, the names *C<sub>0</sub>*, *C<sub>1</sub>*, etc. represent *enumerated elements* for this particular enumerated type. All such elements have distinct values.

#### 20.4.2.1.4 Bitmask types

[bitmask.types]

- 1 Several types defined in ?? through ?? and ?? are *bitmask types*. Each bitmask type can be implemented as an enumerated type that overloads certain operators, as an integer type, or as a *bitset* (??).
- 2 The bitmask type *bitmask* can be written:

```
// For exposition only.
// int_type is an integral type capable of representing all values of the bitmask type.
enum bitmask : int_type {
    V0 = 1 << 0, V1 = 1 << 1, V2 = 1 << 2, V3 = 1 << 3, .....
};

inline constexpr bitmask C0(V0);
inline constexpr bitmask C1(V1);
inline constexpr bitmask C2(V2);
inline constexpr bitmask C3(V3);
....
```

---

<sup>164)</sup> Such as an integer type, with constant integer values (??).

```

constexpr bitmask operator&(bitmask X, bitmask Y) {
    return static_cast<bitmask>(
        static_cast<int_type>(X) & static_cast<int_type>(Y));
}

constexpr bitmask operator|(bitmask X, bitmask Y) {
    return static_cast<bitmask>(
        static_cast<int_type>(X) | static_cast<int_type>(Y));
}

constexpr bitmask operator^(bitmask X, bitmask Y){
    return static_cast<bitmask>(
        static_cast<int_type>(X) ^ static_cast<int_type>(Y));
}

constexpr bitmask operator~(bitmask X){
    return static_cast<bitmask>(~static_cast<int_type>(X));
}

bitmask& operator&=(bitmask& X, bitmask Y){
    X = X & Y; return X;
}

bitmask& operator|=(bitmask& X, bitmask Y) {
    X = X | Y; return X;
}

bitmask& operator^=(bitmask& X, bitmask Y) {
    X = X ^ Y; return X;
}

```

<sup>3</sup> Here, the names  $C_0$ ,  $C_1$ , etc. represent *bitmask elements* for this particular bitmask type. All such elements have distinct, nonzero values such that, for any pair  $C_i$  and  $C_j$  where  $i \neq j$ ,  $C_i \& C_j$  is nonzero and  $C_i \& C_j$  is zero. Additionally, the value 0 is used to represent an *empty bitmask*, in which no bitmask elements are set.

<sup>4</sup> The following terms apply to objects and values of bitmask types:

- (4.1) — To *set* a value  $Y$  in an object  $X$  is to evaluate the expression  $X |= Y$ .
- (4.2) — To *clear* a value  $Y$  in an object  $X$  is to evaluate the expression  $X &= \sim Y$ .
- (4.3) — The value  $Y$  is *set* in the object  $X$  if the expression  $X \& Y$  is nonzero.

#### 20.4.2.1.5 Character sequences

[character.seq]

<sup>1</sup> The C standard library makes widespread use of characters and character sequences that follow a few uniform conventions:

- (1.1) — A *letter* is any of the 26 lowercase or 26 uppercase letters in the basic execution character set.
- (1.2) — The *decimal-point character* is the (single-byte) character used by functions that convert between a (single-byte) character sequence and a value of one of the floating-point types. It is used in the character sequence to denote the beginning of a fractional part. It is represented in ?? through ?? and ?? by a period, '.', which is also its value in the "C" locale, but may change during program execution by a call to `setlocale(int, const char*)`,<sup>165</sup> or by a change to a `locale` object, as described in ?? and ??.
- (1.3) — A *character sequence* is an array object (??)  $A$  that can be declared as  $T A[N]$ , where  $T$  is any of the types `char`, `unsigned char`, or `signed char` (??), optionally qualified by any combination of `const`

<sup>165</sup>) declared in `<clocale>` (??).

or **volatile**. The initial elements of the array have defined contents up to and including an element determined by some predicate. A character sequence can be designated by a pointer value *S* that points to its first element.

#### 20.4.2.1.5.1 Byte strings

[**byte.strings**]

- <sup>1</sup> A *null-terminated byte string*, or NTBS, is a character sequence whose highest-addressed element with defined content has the value zero (the *terminating null character*); no other element in the sequence has the value zero.<sup>166</sup>
- <sup>2</sup> The *length* of an NTBS is the number of elements that precede the terminating null character. An *empty* NTBS has a length of zero.
- <sup>3</sup> The *value* of an NTBS is the sequence of values of the elements up to and including the terminating null character.
- <sup>4</sup> A *static* NTBS is an NTBS with static storage duration.<sup>167</sup>

#### 20.4.2.1.5.2 Multibyte strings

[**multibyte.strings**]

- <sup>1</sup> A *null-terminated multibyte string*, or NTMBS, is an NTBS that constitutes a sequence of valid multibyte characters, beginning and ending in the initial shift state.<sup>168</sup>
- <sup>2</sup> A *static* NTMBS is an NTMBS with static storage duration.

#### 20.4.2.2 Functions within classes

[**functions.within.classes**]

- <sup>1</sup> For the sake of exposition, ?? through ?? and ?? do not describe copy/move constructors, assignment operators, or (non-virtual) destructors with the same apparent semantics as those that can be generated by default (??, ??, ??). It is unspecified whether the implementation provides explicit definitions for such member function signatures, or for virtual destructors that can be generated by default.
- <sup>2</sup> For the sake of exposition, the library clauses sometimes annotate constructors with *EXPLICIT*. Such a constructor is conditionally declared as either explicit or non-explicit (??). [Note: This is typically implemented by declaring two such constructors, of which at most one participates in overload resolution. —end note]

#### 20.4.2.3 Operators

[**operators**]

- <sup>1</sup> In this library, whenever a declaration is provided for an `operator!=`, `operator>`, `operator>=`, or `operator<=` for a type T, its requirements and semantics are as follows, unless explicitly specified otherwise.

`bool operator!=(const T& x, const T& y);`  
<sup>2</sup> *Requires:* Type T is `EqualityComparable` (Table ??).  
<sup>3</sup> *Returns:* !(x == y).

`bool operator>(const T& x, const T& y);`  
<sup>4</sup> *Requires:* Type T is `LessThanComparable` (Table ??).  
<sup>5</sup> *Returns:* y < x.

<sup>166</sup>) Many of the objects manipulated by function signatures declared in `<cstring>` (??) are character sequences or NTBSS. The size of some of these character sequences is limited by a length value, maintained separately from the character sequence.

<sup>167</sup>) A string literal, such as "abc", is a static NTBS.

<sup>168</sup>) An NTBS that contains characters only from the basic execution character set is also an NTMBS. Each multibyte character then consists of a single byte.

```

bool operator<=(const T& x, const T& y);
6   Requires: Type T is LessThanComparable (Table ??).
7   Returns: !(y < x).

bool operator>=(const T& x, const T& y);
8   Requires: Type T is LessThanComparable (Table ??).
9   Returns: !(x < y).

```

#### 20.4.2.4 Private members

[objects.within.classes]

- <sup>1</sup> ?? through ?? and ?? do not specify the representation of classes, and intentionally omit specification of class members (??). An implementation may define static or non-static class members, or both, as needed to implement the semantics of the member functions specified in ?? through ?? and ??.
- <sup>2</sup> For the sake of exposition, some subclauses provide representative declarations, and semantic requirements, for private members of classes that meet the external specifications of the classes. The declarations for such members are followed by a comment that ends with *exposition only*, as in:

```
streambuf* sb; // exposition only
```

- <sup>3</sup> An implementation may use any technique that provides equivalent observable behavior.

#### 20.5 Library-wide requirements

[requirements]

- <sup>1</sup> This subclause specifies requirements that apply to the entire C++ standard library. ?? through ?? and ?? specify the requirements of individual entities within the library.
- <sup>2</sup> Requirements specified in terms of interactions between threads do not apply to programs having only a single thread of execution.
- <sup>3</sup> Within this subclause, ?? describes the library's contents and organization, ?? describes how well-formed C++ programs gain access to library entities, ?? describes constraints on types and functions used with the C++ standard library, ?? describes constraints on well-formed C++ programs, and ?? describes constraints on conforming implementations.

#### 20.5.1 Library contents and organization

[organization]

- <sup>1</sup> ?? describes the entities and macros defined in the C++ standard library. ?? lists the standard library headers and some constraints on those headers. ?? lists requirements for a freestanding implementation of the C++ standard library.

##### 20.5.1.1 Library contents

[contents]

- <sup>1</sup> The C++ standard library provides definitions for the entities and macros described in the synopses of the C++ standard library headers (??).
- <sup>2</sup> All library entities except `operator new` and `operator delete` are defined within the namespace `std` or namespaces nested within namespace `std`.<sup>169</sup> It is unspecified whether names declared in a specific namespace are declared directly in that namespace or in an inline namespace inside that namespace.<sup>170</sup>

<sup>169)</sup> The C standard library headers (??) also define names within the global namespace, while the C++ headers for C library facilities (??) may also define names within the global namespace.

<sup>170)</sup> This gives implementers freedom to use inline namespaces to support multiple configurations of the library.

- <sup>3</sup> Whenever a name *x* defined in the standard library is mentioned, the name *x* is assumed to be fully qualified as `::std::x`, unless explicitly described otherwise. For example, if the *Effects:* element for library function *F* is described as calling library function *G*, the function `::std::G` is meant.

### 20.5.1.2 Headers

[headers]

- 1 Each element of the C++ standard library is declared or defined (as appropriate) in a *header*.<sup>171</sup>  
C++ 标准库的每一个元素都会在一个 *header* 中声明或定义。<sup>172</sup>
- 2 The C++ standard library provides the *C++ library headers*, shown in Table ??.

Table 16 — C++ library headers

|                                         |                                       |                                       |                                    |
|-----------------------------------------|---------------------------------------|---------------------------------------|------------------------------------|
| <code>&lt;algorithm&gt;</code>          | <code>&lt;fstream&gt;</code>          | <code>&lt;mutex&gt;</code>            | <code>&lt;string&gt;</code>        |
| <code>&lt;any&gt;</code>                | <code>&lt;functional&gt;</code>       | <code>&lt;new&gt;</code>              | <code>&lt;string_view&gt;</code>   |
| <code>&lt;array&gt;</code>              | <code>&lt;future&gt;</code>           | <code>&lt;numeric&gt;</code>          | <code>&lt;strstream&gt;</code>     |
| <code>&lt;atomic&gt;</code>             | <code>&lt;initializer_list&gt;</code> | <code>&lt;optional&gt;</code>         | <code>&lt;syncstream&gt;</code>    |
| <code>&lt;bitset&gt;</code>             | <code>&lt;iomanip&gt;</code>          | <code>&lt;ostream&gt;</code>          | <code>&lt;system_error&gt;</code>  |
| <code>&lt;charconv&gt;</code>           | <code>&lt;ios&gt;</code>              | <code>&lt;queue&gt;</code>            | <code>&lt;thread&gt;</code>        |
| <code>&lt;chrono&gt;</code>             | <code>&lt;iostfwd&gt;</code>          | <code>&lt;random&gt;</code>           | <code>&lt;tuple&gt;</code>         |
| <code>&lt;codecvt&gt;</code>            | <code>&lt;iostream&gt;</code>         | <code>&lt;ratio&gt;</code>            | <code>&lt;type_traits&gt;</code>   |
| <code>&lt;compare&gt;</code>            | <code>&lt;istream&gt;</code>          | <code>&lt;regex&gt;</code>            | <code>&lt;typeindex&gt;</code>     |
| <code>&lt;complex&gt;</code>            | <code>&lt;iterator&gt;</code>         | <code>&lt;scoped_allocator&gt;</code> | <code>&lt;typeinfo&gt;</code>      |
| <code>&lt;condition_variable&gt;</code> | <code>&lt;limits&gt;</code>           | <code>&lt;set&gt;</code>              | <code>&lt;unordered_map&gt;</code> |
| <code>&lt;deque&gt;</code>              | <code>&lt;list&gt;</code>             | <code>&lt;shared_mutex&gt;</code>     | <code>&lt;unordered_set&gt;</code> |
| <code>&lt;exception&gt;</code>          | <code>&lt;locale&gt;</code>           | <code>&lt;sstream&gt;</code>          | <code>&lt;utility&gt;</code>       |
| <code>&lt;execution&gt;</code>          | <code>&lt;map&gt;</code>              | <code>&lt;stack&gt;</code>            | <code>&lt;valarray&gt;</code>      |
| <code>&lt;filesystem&gt;</code>         | <code>&lt;memory&gt;</code>           | <code>&lt;stdexcept&gt;</code>        | <code>&lt;variant&gt;</code>       |
| <code>&lt;forward_list&gt;</code>       | <code>&lt;memory_resource&gt;</code>  | <code>&lt;streambuf&gt;</code>        | <code>&lt;vector&gt;</code>        |

- <sup>3</sup> The facilities of the C standard library are provided in the additional headers shown in Table ??.<sup>173</sup>

Table 17 — C++ headers for C library facilities

|                               |                                |                                |                              |                              |
|-------------------------------|--------------------------------|--------------------------------|------------------------------|------------------------------|
| <code>&lt;cassert&gt;</code>  | <code>&lt;cinttypes&gt;</code> | <code>&lt;csignal&gt;</code>   | <code>&lt;cstdio&gt;</code>  | <code>&lt;cwchar&gt;</code>  |
| <code>&lt;ccomplex&gt;</code> | <code>&lt;ciso646&gt;</code>   | <code>&lt;cstdalign&gt;</code> | <code>&lt;cstdlib&gt;</code> | <code>&lt;cwctype&gt;</code> |
| <code>&lt;cctype&gt;</code>   | <code>&lt;climits&gt;</code>   | <code>&lt;cstdarg&gt;</code>   | <code>&lt;cstring&gt;</code> |                              |
| <code>&lt;cerrno&gt;</code>   | <code>&lt;clocale&gt;</code>   | <code>&lt;cstdbool&gt;</code>  | <code>&lt;ctgmath&gt;</code> |                              |
| <code>&lt;cfenv&gt;</code>    | <code>&lt;cmath&gt;</code>     | <code>&lt;cstddef&gt;</code>   | <code>&lt;ctime&gt;</code>   |                              |
| <code>&lt;cfloat&gt;</code>   | <code>&lt;csetjmp&gt;</code>   | <code>&lt;cstdint&gt;</code>   | <code>&lt;cuchar&gt;</code>  |                              |

- <sup>4</sup> Except as noted in ?? through ?? and ??, the contents of each header *cname* is the same as that of the corresponding header *name.h* as specified in the C standard library (??). In the C++ standard library, however, the declarations (except for names which are defined as macros in C) are within namespace scope (??) of the namespace `std`. It is unspecified whether these names (including any overloads added in ?? through ?? and ??) are first declared within the global namespace scope and are then injected into namespace `std` by explicit *using-declarations* (??).
- <sup>5</sup> Names which are defined as macros in C shall be defined as macros in the C++ standard library, even if C grants license for implementation as functions. [Note: The names defined as macros in C include the following: `assert`, `offsetof`, `setjmp`, `va_arg`, `va_end`, and `va_start`. — end note]

171) A header is not necessarily a source file, nor are the sequences delimited by `<` and `>` in header names necessarily valid source file names (??).

172) 一个标头不一定是一个源文件，也不一定是在具有有效源文件名的标头名中被 `<` 和 `>` 分隔的序列 (??)

173) It is intentional that there is no C++ header for any of these C headers: `<stdatomic.h>`, `<stdnoreturn.h>`, `<threads.h>`.

- <sup>6</sup> Names that are defined as functions in C shall be defined as functions in the C++ standard library.<sup>174</sup>
- <sup>7</sup> Identifiers that are keywords or operators in C++ shall not be defined as macros in C++ standard library headers.<sup>175</sup>
- <sup>8</sup> ??, C standard library headers, describes the effects of using the `name.h` (C header) form in a C++ program.<sup>176</sup>
- <sup>9</sup> Annex K of the C standard describes a large number of functions, with associated types and macros, which “promote safer, more secure programming” than many of the traditional C library functions. The names of the functions have a suffix of `_s`; most of them provide the same service as the C library function with the unsuffixed name, but generally take an additional argument whose value is the size of the result array. If any C++ header is included, it is implementation-defined whether any of these names is declared in the global namespace. (None of them is declared in namespace `std`.)
- <sup>10</sup> Table ?? lists the Annex K names that may be declared in some header. These names are also subject to the restrictions of ??.

Table 18 — C standard Annex K names

|                                   |                                       |                           |                          |
|-----------------------------------|---------------------------------------|---------------------------|--------------------------|
| <code>abort_handler_s</code>      | <code>mbstowcs_s</code>               | <code>strncat_s</code>    | <code>vswscanf_s</code>  |
| <code>asctime_s</code>            | <code>memcpy_s</code>                 | <code>strncpy_s</code>    | <code>vwprintf_s</code>  |
| <code>bsearch_s</code>            | <code>memmove_s</code>                | <code>strtok_s</code>     | <code>vwscanf_s</code>   |
| <code>constraint_handler_t</code> | <code>memset_s</code>                 | <code>swprintf_s</code>   | <code>wcrtomb_s</code>   |
| <code>ctime_s</code>              | <code>printf_s</code>                 | <code>swscanf_s</code>    | <code>wcscat_s</code>    |
| <code>errno_t</code>              | <code>qsort_s</code>                  | <code>tmpfile_s</code>    | <code>wcscpy_s</code>    |
| <code>fopen_s</code>              | <code>RSIZE_MAX</code>                | <code>TMP_MAX_S</code>    | <code>wcsncat_s</code>   |
| <code>fprintf_s</code>            | <code>rsize_t</code>                  | <code>tmpnam_s</code>     | <code>wcsncpy_s</code>   |
| <code>freopen_s</code>            | <code>scanf_s</code>                  | <code>vfprintf_s</code>   | <code>wcsnlen_s</code>   |
| <code>fscanf_s</code>             | <code>set_constraint_handler_s</code> | <code>vfscanf_s</code>    | <code>wcsrtombs_s</code> |
| <code>fwprintf_s</code>           | <code>snprintf_s</code>               | <code>vfwprintf_s</code>  | <code>wcstok_s</code>    |
| <code>fwscanf_s</code>            | <code>snwprintf_s</code>              | <code>vfwscanf_s</code>   | <code>wcstombs_s</code>  |
| <code>getenv_s</code>             | <code>sprintf_s</code>                | <code>vprintf_s</code>    | <code>wctomb_s</code>    |
| <code>gets_s</code>               | <code>sscanf_s</code>                 | <code>vscanf_s</code>     | <code>wmemcpy_s</code>   |
| <code>gmtime_s</code>             | <code>strcat_s</code>                 | <code>vsprintf_s</code>   | <code>wmemmove_s</code>  |
| <code>ignore_handler_s</code>     | <code>strcpy_s</code>                 | <code>vsnwprintf_s</code> | <code>wprintf_s</code>   |
| <code>L_tmpnam_s</code>           | <code>strerror_s</code>               | <code>vsprintf_s</code>   | <code>wscanf_s</code>    |
| <code>localtime_s</code>          | <code>strerrorlen_s</code>            | <code>vscanf_s</code>     |                          |
| <code>mbsrtowcs_s</code>          | <code>strlen_s</code>                 | <code>vswprintf_s</code>  |                          |

## 20.5.1.3 Freestanding implementations

[compliance]

- <sup>1</sup> Two kinds of implementations are defined: *hosted* and *freestanding* (??). For a hosted implementation, this document describes the set of available headers.
- <sup>2</sup> A freestanding implementation has an implementation-defined set of headers. This set shall include at least the headers shown in Table ??.
- <sup>3</sup> The supplied version of the header `<cstdlib>` shall declare at least the functions `abort`, `atexit`, `at_quick_exit`, `exit`, and `quick_exit` (??). The other headers listed in this table shall meet the same requirements as for a hosted implementation.

<sup>174</sup>) This disallows the practice, allowed in C, of providing a masking macro in addition to the function prototype. The only way to achieve equivalent inline behavior in C++ is to provide a definition as an `extern inline` function.

<sup>175</sup>) In particular, including the standard header `<iso646.h>` or `<ciso646>` has no effect.

<sup>176</sup>) The `".h"` headers dump all their names into the global namespace, whereas the newer forms keep their names in namespace `std`. Therefore, the newer forms are the preferred forms for all uses except for C++ programs which are intended to be strictly compatible with C.

Table 19 — C++ headers for freestanding implementations

| Subclause                    | Header(s)                                                  |
|------------------------------|------------------------------------------------------------|
|                              | <code>&lt;ciso646&gt;</code>                               |
| ?? Types                     | <code>&lt;cstddef&gt;</code>                               |
| ?? Implementation properties | <code>&lt;cfloat&gt; &lt;limits&gt; &lt;climits&gt;</code> |
| ?? Integer types             | <code>&lt;cstdint&gt;</code>                               |
| ?? Start and termination     | <code>&lt;cstdlib&gt;</code>                               |
| ?? Dynamic memory management | <code>&lt;new&gt;</code>                                   |
| ?? Type identification       | <code>&lt;typeinfo&gt;</code>                              |
| ?? Exception handling        | <code>&lt;exception&gt;</code>                             |
| ?? Initializer lists         | <code>&lt;initializer_list&gt;</code>                      |
| ?? Other runtime support     | <code>&lt;cstdarg&gt;</code>                               |
| ?? Type traits               | <code>&lt;type_traits&gt;</code>                           |
| ?? Atomics                   | <code>&lt;atomic&gt;</code>                                |
| ??, ?? Deprecated headers    | <code>&lt;cstdalign&gt; &lt;cstdbool&gt;</code>            |

## 20.5.2 Using the library

[using]

### 20.5.2.1 Overview

[using.overview]

- <sup>1</sup> Subclause ?? describes how a C++ program gains access to the facilities of the C++ standard library. ?? describes effects during translation phase 4, while ?? describes effects during phase 8 (??).

### 20.5.2.2 Headers

[using.headers]

- <sup>1</sup> The entities in the C++ standard library are defined in headers, whose contents are made available to a translation unit when it contains the appropriate `#include` preprocessing directive (??).
- <sup>2</sup> A translation unit may include library headers in any order (??). Each may be included more than once, with no effect different from being included exactly once, except that the effect of including either `<cassert>` or `<assert.h>` depends each time on the lexically current definition of `NDEBUG`.<sup>177</sup>
- <sup>3</sup> A translation unit shall include a header only outside of any declaration or definition, and shall include the header lexically before the first reference in that translation unit to any of the entities declared in that header. No diagnostic is required.

### 20.5.2.3 Linkage

[using.linkage]

- <sup>1</sup> Entities in the C++ standard library have external linkage (??). Unless otherwise specified, objects and functions have the default `extern "C++"` linkage (??).
- <sup>2</sup> Whether a name from the C standard library declared with external linkage has `extern "C"` or `extern "C++"` linkage is implementation-defined. It is recommended that an implementation use `extern "C++"` linkage for this purpose.<sup>178</sup>
- <sup>3</sup> Objects and functions defined in the library and required by a C++ program are included in the program prior to program startup.
- <sup>4</sup> See also replacement functions (??), runtime changes (??).

<sup>177</sup> This is the same as the C standard library.

<sup>178</sup> The only reliable way to declare an object or function signature from the C standard library is by including the header that declares it, notwithstanding the latitude granted in 7.1.4 of the C Standard.

### 20.5.3 Requirements on types and expressions

[utility.requirements]

- <sup>1</sup> ?? describes requirements on types and expressions used to instantiate templates defined in the C++ standard library. ?? describes the requirements on swappable types and swappable expressions. ?? describes the requirements on pointer-like types that support null values. ?? describes the requirements on hash function objects. ?? describes the requirements on storage allocators.

#### 20.5.3.1 Template argument requirements

[utility.arg.requirements]

- <sup>1</sup> The template definitions in the C++ standard library refer to various named requirements whose details are set out in Tables ??–???. In these tables, T is an object or reference type to be supplied by a C++ program instantiating a template; a, b, and c are values of type (possibly const) T; s and t are modifiable lvalues of type T; u denotes an identifier; rv is an rvalue of type T; and v is an lvalue of type (possibly const) T or an rvalue of type const T.
- <sup>2</sup> In general, a default constructor is not required. Certain container class member function signatures specify T() as a default argument. T() shall be a well-defined expression (??) if one of those signatures is called using the default argument (??).

Table 20 — EqualityComparable requirements

| Expression | Return type            | Requirement                                                                                                                                                                                                                      |
|------------|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| a == b     | convertible to<br>bool | == is an equivalence relation, that is, it has the following properties: <ul style="list-style-type: none"> <li>— For all a, a == a.</li> <li>— If a == b, then b == a.</li> <li>— If a == b and b == c, then a == c.</li> </ul> |

Table 21 — LessThanComparable requirements

| Expression | Return type            | Requirement                               |
|------------|------------------------|-------------------------------------------|
| a < b      | convertible to<br>bool | < is a strict weak ordering relation (??) |

Table 22 — DefaultConstructible requirements

| Expression | Post-condition                                                    |
|------------|-------------------------------------------------------------------|
| T t;       | object t is default-initialized                                   |
| T u{};     | object u is value-initialized or aggregate-initialized            |
| T()        | an object of type T is value-initialized or aggregate-initialized |
| T{}        |                                                                   |

#### 20.5.3.2 Swappable requirements

[swappable.requirements]

- <sup>1</sup> This subclause provides definitions for swappable types and expressions. In these definitions, let t denote an expression of type T, and let u denote an expression of type U.
- <sup>2</sup> An object t is *swappable with* an object u if and only if:

Table 23 — MoveConstructible requirements

| Expression                                                                                                                                                                                                                                                                           | Post-condition                                                                           |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------|
| <code>T u = rv;</code>                                                                                                                                                                                                                                                               | <code>u</code> is equivalent to the value of <code>rv</code> before the construction     |
| <code>T(rv)</code>                                                                                                                                                                                                                                                                   | <code>T(rv)</code> is equivalent to the value of <code>rv</code> before the construction |
| <code>rv</code> 's state is unspecified [ <i>Note:</i> <code>rv</code> must still meet the requirements of the library component that is using it. The operations listed in those requirements must work as specified whether <code>rv</code> has been moved from or not. —end note] |                                                                                          |

Table 24 — CopyConstructible requirements (in addition to MoveConstructible)

| Expression            | Post-condition                                                                  |
|-----------------------|---------------------------------------------------------------------------------|
| <code>T u = v;</code> | the value of <code>v</code> is unchanged and is equivalent to <code>u</code>    |
| <code>T(v)</code>     | the value of <code>v</code> is unchanged and is equivalent to <code>T(v)</code> |

Table 25 — MoveAssignable requirements

| Expression                                                                                                                                                                                                                                                                                                                                                        | Return type         | Return value   | Post-condition                                                                                                                                            |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>t = rv</code>                                                                                                                                                                                                                                                                                                                                               | <code>T&amp;</code> | <code>t</code> | If <code>t</code> and <code>rv</code> do not refer to the same object, <code>t</code> is equivalent to the value of <code>rv</code> before the assignment |
| <code>rv</code> 's state is unspecified. [ <i>Note:</i> <code>rv</code> must still meet the requirements of the library component that is using it, whether or not <code>t</code> and <code>rv</code> refer to the same object. The operations listed in those requirements must work as specified whether <code>rv</code> has been moved from or not. —end note] |                     |                |                                                                                                                                                           |

Table 26 — CopyAssignable requirements (in addition to MoveAssignable)

| Expression         | Return type         | Return value   | Post-condition                                                                            |
|--------------------|---------------------|----------------|-------------------------------------------------------------------------------------------|
| <code>t = v</code> | <code>T&amp;</code> | <code>t</code> | <code>t</code> is equivalent to <code>v</code> , the value of <code>v</code> is unchanged |

Table 27 — Destructible requirements

| Expression          | Post-condition                                                                   |
|---------------------|----------------------------------------------------------------------------------|
| <code>u.~T()</code> | All resources owned by <code>u</code> are reclaimed, no exception is propagated. |

- (2.1) — the expressions `swap(t, u)` and `swap(u, t)` are valid when evaluated in the context described below, and
- (2.2) — these expressions have the following effects:
  - (2.2.1) — the object referred to by `t` has the value originally held by `u` and
  - (2.2.2) — the object referred to by `u` has the value originally held by `t`.

<sup>3</sup> The context in which `swap(t, u)` and `swap(u, t)` are evaluated shall ensure that a binary non-member function named “swap” is selected via overload resolution (??) on a candidate set that includes:

- (3.1) — the two `swap` function templates defined in `<utility>` (??) and
- (3.2) — the lookup set produced by argument-dependent lookup (??).

[*Note:* If T and U are both fundamental types or arrays of fundamental types and the declarations from the header <utility> are in scope, the overall lookup set described above is equivalent to that of the qualified name lookup applied to the expression std::swap(t, u) or std::swap(u, t) as appropriate. —end note]

[*Note:* It is unspecified whether a library component that has a swappable requirement includes the header <utility> to ensure an appropriate evaluation context. —end note]

- <sup>4</sup> An rvalue or lvalue t is *swappable* if and only if t is swappable with any rvalue or lvalue, respectively, of type T.
- <sup>5</sup> A type X satisfying any of the iterator requirements (??) satisfies the requirements of ValueSwappable if, for any dereferenceable object x of type X, \*x is swappable.

[*Example:* User code can ensure that the evaluation of swap calls is performed in an appropriate context under the various conditions as follows:

```
#include <utility>

// Requires: std::forward<T>(t) shall be swappable with std::forward<U>(u).
template<class T, class U>
void value_swap(T&& t, U&& u) {
    using std::swap;
    swap(std::forward<T>(t), std::forward<U>(u)); // OK: uses "swappable with" conditions
  // for rvalues and lvalues
}

// Requires: lvalues of T shall be swappable.
template<class T>
void lv_swap(T& t1, T& t2) {
    using std::swap;
    swap(t1, t2); // OK: uses swappable conditions for lvalues of type T
}

namespace N {
    struct A { int m; };
    struct Proxy { A* a; };
    Proxy proxy(A& a) { return Proxy{ &a }; }

    void swap(A& x, Proxy p) {
        std::swap(x.m, p.a->m); // OK: uses context equivalent to swappable
                                // conditions for fundamental types
    }
    void swap(Proxy p, A& x) { swap(x, p); } // satisfy symmetry constraint
}

int main() {
    int i = 1, j = 2;
    lv_swap(i, j);
    assert(i == 2 && j == 1);

    N::A a1 = { 5 }, a2 = { -5 };
    value_swap(a1, proxy(a2));
}
```

```

    assert(a1.m == -5 && a2.m == 5);
}

— end example]

```

### 20.5.3.3 NullablePointer requirements

[nullablepointer.requirements]

- <sup>1</sup> A **NullablePointer** type is a pointer-like type that supports null values. A type **P** meets the requirements of **NullablePointer** if:
  - (1.1) — **P** satisfies the requirements of **EqualityComparable**, **DefaultConstructible**, **CopyConstructible**, **CopyAssignable**, and **Destructible**,
  - (1.2) — lvalues of type **P** are swappable (??),
  - (1.3) — the expressions shown in Table ?? are valid and have the indicated semantics, and
  - (1.4) — **P** satisfies all the other requirements of this subclause.
- <sup>2</sup> A value-initialized object of type **P** produces the null value of the type. The null value shall be equivalent only to itself. A default-initialized object of type **P** may have an indeterminate value. [Note: Operations involving indeterminate values may cause undefined behavior. — end note]
- <sup>3</sup> An object **p** of type **P** can be contextually converted to **bool** (??). The effect shall be as if **p != nullptr** had been evaluated in place of **p**.
- <sup>4</sup> No operation which is part of the **NullablePointer** requirements shall exit via an exception.
- <sup>5</sup> In Table ??, **u** denotes an identifier, **t** denotes a non-const lvalue of type **P**, **a** and **b** denote values of type (possibly **const**) **P**, and **np** denotes a value of type (possibly **const**) **std::nullptr\_t**.

Table 28 — **NullablePointer** requirements

| Expression       | Return type                             | Operational semantics                          |
|------------------|-----------------------------------------|------------------------------------------------|
| <b>P u(np);</b>  |                                         | <i>Postconditions:</i> <b>u == nullptr</b>     |
| <b>P u = np;</b> |                                         | <i>Postconditions:</i> <b>P(np) == nullptr</b> |
| <b>P(np)</b>     |                                         | <i>Postconditions:</i> <b>P(np) == nullptr</b> |
| <b>t = np</b>    | <b>P&amp;</b>                           | <i>Postconditions:</i> <b>t == nullptr</b>     |
| <b>a != b</b>    | contextually convertible to <b>bool</b> | <b>!(a == b)</b>                               |
| <b>a == np</b>   | contextually convertible to <b>bool</b> | <b>a == P()</b>                                |
| <b>np == a</b>   |                                         |                                                |
| <b>a != np</b>   | contextually convertible to <b>bool</b> | <b>!(a == np)</b>                              |
| <b>np != a</b>   |                                         |                                                |

### 20.5.3.4 Hash requirements

[hash.requirements]

- <sup>1</sup> A type **H** meets the **Hash** requirements if:
  - (1.1) — it is a function object type (??),
  - (1.2) — it satisfies the requirements of **CopyConstructible** and **Destructible** (??), and
  - (1.3) — the expressions shown in Table ?? are valid and have the indicated semantics.
- <sup>2</sup> Given **Key** is an argument type for function objects of type **H**, in Table ?? **h** is a value of type (possibly **const**) **H**, **u** is an lvalue of type **Key**, and **k** is a value of a type convertible to (possibly **const**) **Key**.

### 20.5.3.5 Allocator requirements

[allocator.requirements]

- <sup>1</sup> The library describes a standard set of requirements for *allocators*, which are class-type objects that encapsulate the information about an allocation model. This information includes the knowledge of pointer types, the type

Table 29 — Hash requirements

| Expression        | Return type         | Requirement                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>h(k)</code> | <code>size_t</code> | The value returned shall depend only on the argument <code>k</code> for the duration of the program. [ <i>Note:</i> Thus all evaluations of the expression <code>h(k)</code> with the same value for <code>k</code> yield the same result for a given execution of the program. — <i>end note</i> ] [ <i>Note:</i> For two different values <code>t1</code> and <code>t2</code> , the probability that <code>h(t1)</code> and <code>h(t2)</code> compare equal should be very small, approaching <code>1.0 / numeric_limits&lt;size_t&gt;::max()</code> . — <i>end note</i> ] |
| <code>h(u)</code> | <code>size_t</code> | Shall not modify <code>u</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

of their difference, the type of the size of objects in this allocation model, as well as the memory allocation and deallocation primitives for it. All of the string types (??), containers (??) (except array), string buffers and string streams (??), and `match_results` (??) are parameterized in terms of allocators.

- 2 The class template `allocator_traits` (??) supplies a uniform interface to all allocator types. Table ?? describes the types manipulated through allocators. Table ?? describes the requirements on allocator types and thus on types used to instantiate `allocator_traits`. A requirement is optional if the last column of Table ?? specifies a default for a given expression. Within the standard library `allocator_traits` template, an optional requirement that is not supplied by an allocator is replaced by the specified default expression. A user specialization of `allocator_traits` may provide different defaults and may provide defaults for different requirements than the primary template. Within Tables ?? and ??, the use of `move` and `forward` always refers to `std::move` and `std::forward`, respectively.

Table 30 — Descriptive variable definitions

| Variable      Definition |                                                                                                                                     |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <code>T, U, C</code>     | any <i>cv</i> -unqualified object type (??)                                                                                         |
| <code>X</code>           | an Allocator class for type <code>T</code>                                                                                          |
| <code>Y</code>           | the corresponding Allocator class for type <code>U</code>                                                                           |
| <code>XX</code>          | the type <code>allocator_traits&lt;X&gt;</code>                                                                                     |
| <code>YY</code>          | the type <code>allocator_traits&lt;Y&gt;</code>                                                                                     |
| <code>a, a1, a2</code>   | lvalues of type <code>X</code>                                                                                                      |
| <code>u</code>           | the name of a variable being declared                                                                                               |
| <code>b</code>           | a value of type <code>Y</code>                                                                                                      |
| <code>c</code>           | a pointer of type <code>C*</code> through which indirection is valid                                                                |
| <code>p</code>           | a value of type <code>XX::pointer</code> , obtained by calling<br><code>a1.allocate</code> , where <code>a1 == a</code>             |
| <code>q</code>           | a value of type <code>XX::const_pointer</code> obtained by conversion<br>from a value <code>p</code> .                              |
| <code>r</code>           | a value of type <code>T&amp;</code> obtained by the expression <code>*p</code> .                                                    |
| <code>w</code>           | a value of type <code>XX::void_pointer</code> obtained by conversion<br>from a value <code>p</code>                                 |
| <code>x</code>           | a value of type <code>XX::const_void_pointer</code> obtained by<br>conversion from a value <code>q</code> or a value <code>w</code> |

Table 30 — Descriptive variable definitions (continued)

| Variable | Definition                                                                                                                                                  |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| y        | a value of type XX::const_void_pointer obtained by conversion from a result value of YY::allocate, or else a value of type (possibly const) std::nullptr_t. |
| n        | a value of type XX::size_type.                                                                                                                              |
| Args     | a template parameter pack                                                                                                                                   |
| args     | a function parameter pack with the pattern Args&&                                                                                                           |

| <code>a1 == a2</code>                                               | <code>bool</code>                                                              | returns <code>true</code> only if storage allocated from each can be deallocated via the other.<br><code>operator==</code> shall be reflexive, symmetric, and transitive, and shall not exit via an exception. |                                                                          |
| <code>a1 != a2</code>                                               | <code>bool</code>                                                              | same as <code>!(a1 == a2)</code>                                                                                                                                                                               |                                                                          |
| <code>a == b</code>                                                 | <code>bool</code>                                                              | same as <code>a == Y::rebind&lt;T&gt;::other(b)</code>                                                                                                                                                         |                                                                          |
| <code>a != b</code>                                                 | <code>bool</code>                                                              | same as <code>!(a == b)</code>                                                                                                                                                                                 |                                                                          |
| <code>X u(a);</code><br><code>X u = a;</code>                       |                                                                                | Shall not exit via an exception.<br><i>Postconditions:</i> <code>u == a</code>                                                                                                                                 |                                                                          |
| <code>X u(b);</code>                                                |                                                                                | Shall not exit via an exception.<br><i>Postconditions:</i> <code>Y(u) == b, u == X(b)</code>                                                                                                                   |                                                                          |
| <code>X u(std::move(a));</code><br><code>X u = std::move(a);</code> |                                                                                | Shall not exit via an exception.<br><i>Postconditions:</i> The value of <code>a</code> is unchanged and is equal to <code>u</code> .                                                                           |                                                                          |
| <code>X u(std::move(b));</code>                                     |                                                                                | Shall not exit via an exception.<br><i>Postconditions:</i> <code>u</code> is equal to the prior value of <code>X(b)</code> .                                                                                   |                                                                          |
| <code>a.construct(c, args)</code>                                   | (not used)                                                                     | <i>Effects:</i> Constructs an object of type <code>C</code> at <code>c</code>                                                                                                                                  | <code>::new ((void*)c) C(forward&lt;Args&gt;(args)...)</code>            |
| <code>a.destroy(c)</code>                                           | (not used)                                                                     | <i>Effects:</i> Destroys the object at <code>c</code>                                                                                                                                                          | <code>c-&gt;~C()</code>                                                  |
| <code>a.select_on_container_copy_construction()</code>              | <code>X</code>                                                                 | Typically returns either <code>a</code> or <code>X()</code>                                                                                                                                                    | <code>return a;</code>                                                   |
| <code>X::propagate_on_container_copy_assignment</code>              | Identical to or derived from <code>true_type</code> or <code>false_type</code> | <code>true_type</code> only if an allocator of type <code>X</code> should be copied when the client container is copy-assigned. See Note B, below.                                                             | <code>false_type</code>                                                  |

Table 31 — Allocator requirements (continued)

| Expression                                | Return type                                                                    | Assertion/note<br>pre-/post-condition                                                                                                                                                      | Default                              |
|-------------------------------------------|--------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------|
| X::propagate_on_container_move_assignment | Identical to or derived from <code>true_type</code> or <code>false_type</code> | <code>true_type</code> only if an allocator of type X should be moved when the client container is move-assigned. See Note B, below.                                                       | <code>false_type</code>              |
| X::propagate_on_container_swap            | Identical to or derived from <code>true_type</code> or <code>false_type</code> | <code>true_type</code> only if an allocator of type X should be swapped when the client container is swapped. See Note B, below.                                                           | <code>false_type</code>              |
| X::is_always_equal                        | Identical to or derived from <code>true_type</code> or <code>false_type</code> | <code>true_type</code> only if the expression <code>a1 == a2</code> is guaranteed to be <code>true</code> for any two (possibly <code>const</code> ) values <code>a1, a2</code> of type X. | <code>is_empty&lt;X&gt;::type</code> |

- <sup>3</sup> Note A: The member class template `rebind` in the table above is effectively a `typedef` template. [Note: In general, if the name `Allocator` is bound to `SomeAllocator<T>`, then `Allocator::rebind<U>::other` is the same type as `SomeAllocator<U>`, where `SomeAllocator<T>::value_type` is `T` and `SomeAllocator<U>::value_type` is `U`. —end note] If `Allocator` is a class template instantiation of the form `SomeAllocator<T, Args>`, where `Args` is zero or more type arguments, and `Allocator` does not supply a `rebind` member template, the standard `allocator_traits` template uses `SomeAllocator<U, Args>` in place of `Allocator::rebind<U>::other` by default. For allocator types that are not template instantiations of the above form, no default is provided.
- <sup>4</sup> Note B: If `X::propagate_on_container_copy_assignment::value` is `true`, X shall satisfy the `CopyAssignable` requirements (Table ??) and the copy operation shall not throw exceptions. If `X::propagate_on_container_move_assignment::value` is `true`, X shall satisfy the `MoveAssignable` requirements (Table ??) and the move operation shall not throw exceptions. If `X::propagate_on_container_swap::value` is `true`, lvalues of type X shall be swappable (??) and the `swap` operation shall not throw exceptions.
- <sup>5</sup> An allocator type X shall satisfy the requirements of `CopyConstructible` (??). The `X::pointer`, `X::const_pointer`, `X::void_pointer`, and `X::const_void_pointer` types shall satisfy the requirements of `NullablePointer` (??). No constructor, comparison function, copy operation, move operation, or swap operation on these pointer types shall exit via an exception. `X::pointer` and `X::const_pointer` shall also satisfy the requirements for a random access iterator (??) and of a contiguous iterator (??).
- <sup>6</sup> Let `x1` and `x2` denote objects of (possibly different) types `X::void_pointer`, `X::const_void_pointer`, `X::pointer`, or `X::const_pointer`. Then, `x1` and `x2` are *equivalently-valued* pointer values, if and only if both `x1` and `x2` can be explicitly converted to the two corresponding objects `px1` and `px2` of type `X::const_pointer`, using a sequence of `static_casts` using only these four types, and the expression `px1 == px2` evaluates to `true`.
- <sup>7</sup> Let `w1` and `w2` denote objects of type `X::void_pointer`. Then for the expressions

```
w1 == w2
w1 != w2
```

either or both objects may be replaced by an equivalently-valued object of type `X::const_void_pointer` with no change in semantics.

- <sup>8</sup> Let `p1` and `p2` denote objects of type `X::pointer`. Then for the expressions

```
p1 == p2
p1 != p2
p1 < p2
p1 <= p2
p1 >= p2
p1 > p2
p1 - p2
```

either or both objects may be replaced by an equivalently-valued object of type `X::const_pointer` with no change in semantics.

- <sup>9</sup> An allocator may constrain the types on which it can be instantiated and the arguments for which its `construct` or `destroy` members may be called. If a type cannot be used with a particular allocator, the allocator class or the call to `construct` or `destroy` may fail to instantiate.

[*Example*: The following is an allocator class template supporting the minimal interface that satisfies the requirements of Table ??:

```
template<class Tp>
struct SimpleAllocator {
    typedef Tp value_type;
    SimpleAllocator(ctor args);

    template<class T> SimpleAllocator(const SimpleAllocator<T>& other);

    [[nodiscard]] Tp* allocate(std::size_t n);
    void deallocate(Tp* p, std::size_t n);
};

template<class T, class U>
bool operator==(const SimpleAllocator<T>&, const SimpleAllocator<U>&);

template<class T, class U>
bool operator!=(const SimpleAllocator<T>&, const SimpleAllocator<U>&);

— end example]
```

- <sup>10</sup> If the alignment associated with a specific over-aligned type is not supported by an allocator, instantiation of the allocator for that type may fail. The allocator also may silently ignore the requested alignment.  
[*Note*: Additionally, the member function `allocate` for that type may fail by throwing an object of type `bad_alloc`. — *end note*]

#### 20.5.3.5.1 Allocator completeness requirements [allocator.requirements.completeness]

- <sup>1</sup> If `X` is an allocator class for type `T`, `X` additionally satisfies the allocator completeness requirements if, whether or not `T` is a complete type:
- (1.1) — `X` is a complete type, and
  - (1.2) — all the member types of `allocator_traits<X>` (??) other than `value_type` are complete types.

## 20.5.4 Constraints on programs [constraints]

### 20.5.4.1 Overview [constraints.overview]

- <sup>1</sup> Subclause ?? describes restrictions on C++ programs that use the facilities of the C++ standard library. The following subclauses specify constraints on the program's use of namespaces (??), its use of various reserved names (??), its use of headers (??), its use of standard library classes as base classes (??), its definitions of replacement functions (??), and its installation of handler functions during execution (??).

### 20.5.4.2 Namespace use [namespace.constraints]

#### 20.5.4.2.1 Namespace std [namespace.std]

- <sup>1</sup> The behavior of a C++ program is undefined if it adds declarations or definitions to namespace `std` or to a namespace within namespace `std` unless otherwise specified. A program may add a template specialization for any standard library template to namespace `std` only if the declaration depends on a user-defined type and the specialization meets the standard library requirements for the original template and is not explicitly prohibited.<sup>180</sup>
- <sup>2</sup> The behavior of a C++ program is undefined if it declares an explicit or partial specialization of any standard library variable template, except where explicitly permitted by the specification of that variable template.
- <sup>3</sup> The behavior of a C++ program is undefined if it declares
- (3.1) — an explicit specialization of any member function of a standard library class template, or
  - (3.2) — an explicit specialization of any member function template of a standard library class or class template, or
  - (3.3) — an explicit or partial specialization of any member class template of a standard library class or class template, or
  - (3.4) — a deduction guide for any standard library class template.

A program may explicitly instantiate a template defined in the standard library only if the declaration depends on the name of a user-defined type and the instantiation meets the standard library requirements for the original template.

- <sup>4</sup> A translation unit shall not declare namespace `std` to be an inline namespace (??).

#### 20.5.4.2.2 Namespace posix [namespace.posix]

- <sup>1</sup> The behavior of a C++ program is undefined if it adds declarations or definitions to namespace `posix` or to a namespace within namespace `posix` unless otherwise specified. The namespace `posix` is reserved for use by ISO/IEC 9945 and other POSIX standards.

#### 20.5.4.2.3 Namespaces for future standardization [namespace.future]

- <sup>1</sup> Top level namespaces with a name starting with `std` and followed by a non-empty sequence of digits are reserved for future standardization. The behavior of a C++ program is undefined if it adds declarations or definitions to such a namespace. [*Example:* The top level namespace `std2` is reserved for use by future revisions of this International Standard. — *end example*]

#### 20.5.4.3 Reserved names [reserved.names]

- <sup>1</sup> The C++ standard library reserves the following kinds of names:

- (1.1) — macros

---

<sup>180</sup>) Any library code that instantiates other library templates must be prepared to work adequately with any user-supplied specialization that meets the minimum requirements of this document.

- (1.2) — global names
- (1.3) — names with external linkage

<sup>2</sup> If a program declares or defines a name in a context where it is reserved, other than as explicitly allowed by this Clause, its behavior is undefined.

#### 20.5.4.3.1 Zombie names

[zombie.names]

<sup>1</sup> In namespace std, the following names are reserved for previous standardization:

- (1.1) — `auto_ptr`,
- (1.2) — `binary_function`,
- (1.3) — `bind1st`,
- (1.4) — `bind2nd`,
- (1.5) — `binder1st`,
- (1.6) — `binder2nd`,
- (1.7) — `const_mem_fun1_ref_t`,
- (1.8) — `const_mem_fun1_t`,
- (1.9) — `const_mem_fun_ref_t`,
- (1.10) — `const_mem_fun_t`,
- (1.11) — `get_unexpected`,
- (1.12) — `mem_fun1_ref_t`,
- (1.13) — `mem_fun1_t`,
- (1.14) — `mem_fun_ref_t`,
- (1.15) — `mem_fun_ref`,
- (1.16) — `mem_fun_t`,
- (1.17) — `mem_fun`,
- (1.18) — `pointer_to_binary_function`,
- (1.19) — `pointer_to_unary_function`,
- (1.20) — `ptr_fun`,
- (1.21) — `random_shuffle`,
- (1.22) — `set_unexpected`,
- (1.23) — `unary_function`,
- (1.24) — `unexpected`, and
- (1.25) — `unexpected_handler`.

#### 20.5.4.3.2 Macro names

[macro.names]

- <sup>1</sup> A translation unit that includes a standard library header shall not `#define` or `#undef` names declared in any standard library header.
- <sup>2</sup> A translation unit shall not `#define` or `#undef` names lexically identical to keywords, to the identifiers listed in Table ??, or to the *attribute-tokens* described in ??.

**20.5.4.3.3 External linkage**

[extern.names]

- <sup>1</sup> Each name declared as an object with external linkage in a header is reserved to the implementation to designate that library object with external linkage,<sup>181</sup> both in namespace `std` and in the global namespace.
- <sup>2</sup> Each global function signature declared with external linkage in a header is reserved to the implementation to designate that function signature with external linkage.<sup>182</sup>
- <sup>3</sup> Each name from the C standard library declared with external linkage is reserved to the implementation for use as a name with `extern "C"` linkage, both in namespace `std` and in the global namespace.
- <sup>4</sup> Each function signature from the C standard library declared with external linkage is reserved to the implementation for use as a function signature with both `extern "C"` and `extern "C++"` linkage,<sup>183</sup> or as a name of namespace scope in the global namespace.

**20.5.4.3.4 Types**

[extern.types]

- <sup>1</sup> For each type `T` from the C standard library,<sup>184</sup> the types `::T` and `std::T` are reserved to the implementation and, when defined, `::T` shall be identical to `std::T`.

**20.5.4.3.5 User-defined literal suffixes**

[usrlit.suffix]

- <sup>1</sup> Literal suffix identifiers (??) that do not start with an underscore are reserved for future standardization.

**20.5.4.4 Headers**

[alt.headers]

- <sup>1</sup> If a file with a name equivalent to the derived file name for one of the C++ standard library headers is not provided as part of the implementation, and a file with that name is placed in any of the standard places for a source file to be included (??), the behavior is undefined.

**20.5.4.5 Derived classes**

[derived.classes]

- <sup>1</sup> Virtual member function signatures defined for a base class in the C++ standard library may be overridden in a derived class defined in the program (??).

**20.5.4.6 Replacement functions**

[replacement.functions]

- <sup>1</sup> ?? through ?? and ?? describe the behavior of numerous functions defined by the C++ standard library. Under some circumstances, however, certain of these function descriptions also apply to replacement functions defined in the program (??).
- <sup>2</sup> A C++ program may provide the definition for any of the following dynamic memory allocation function signatures declared in header `<new>` (??, ??):
 

```
operator new(std::size_t)
operator new(std::size_t, std::align_val_t)
operator new(std::size_t, const std::nothrow_t&)
operator new(std::size_t, std::align_val_t, const std::nothrow_t&)
```

<sup>181</sup>) The list of such reserved names includes `errno`, declared or defined in `<cerrno>`.

<sup>182</sup>) The list of such reserved function signatures with external linkage includes `setjmp(jmp_buf)`, declared or defined in `<csetjmp>`, and `va_end(va_list)`, declared or defined in `<cstdarg>`.

<sup>183</sup>) The function signatures declared in `<cuchar>`, `<cwchar>`, and `<cwtctype>` are always reserved, notwithstanding the restrictions imposed in subclause 4.5.1 of Amendment 1 to the C Standard for these headers.

<sup>184</sup>) These types are `clock_t`, `div_t`, `FILE`, `fpos_t`, `lconv`, `ldiv_t`, `mbstate_t`, `ptrdiff_t`, `sig_atomic_t`, `size_t`, `time_t`, `tm`, `va_list`, `wctrans_t`, `wctype_t`, and `wint_t`.

```

operator delete(void*)
operator delete(void*, std::size_t)
operator delete(void*, std::align_val_t)
operator delete(void*, std::size_t, std::align_val_t)
operator delete(void*, const std::nothrow_t&)
operator delete(void*, std::align_val_t, const std::nothrow_t&)

operator new[](std::size_t)
operator new[](std::size_t, std::align_val_t)
operator new[](std::size_t, const std::nothrow_t&)
operator new[](std::size_t, std::align_val_t, const std::nothrow_t&)

operator delete[](void*)
operator delete[](void*, std::size_t)
operator delete[](void*, std::align_val_t)
operator delete[](void*, std::size_t, std::align_val_t)
operator delete[](void*, const std::nothrow_t&)
operator delete[](void*, std::align_val_t, const std::nothrow_t&)

```

- <sup>3</sup> The program's definitions are used instead of the default versions supplied by the implementation (??). Such replacement occurs prior to program startup (??, ??). The program's declarations shall not be specified as `inline`. No diagnostic is required.

#### 20.5.4.7 Handler functions

[`handler.functions`]

- <sup>1</sup> The C++ standard library provides a default version of the following handler function (??):

(1.1) — `terminate_handler`

- <sup>2</sup> A C++ program may install different handler functions during execution, by supplying a pointer to a function defined in the program or the library as an argument to (respectively):

(2.1) — `set_new_handler`

(2.2) — `set_terminate`

See also subclauses ??, Storage allocation errors, and ??, Exception handling.

- <sup>3</sup> A C++ program can get a pointer to the current handler function by calling the following functions:

(3.1) — `get_new_handler`

(3.2) — `get_terminate`

- <sup>4</sup> Calling the `set_*` and `get_*` functions shall not incur a data race. A call to any of the `set_*` functions shall synchronize with subsequent calls to the same `set_*` function and to the corresponding `get_*` function.

#### 20.5.4.8 Other functions

[`res.on.functions`]

- <sup>1</sup> In certain cases (replacement functions, handler functions, operations on types used to instantiate standard library template components), the C++ standard library depends on components supplied by a C++ program. If these components do not meet their requirements, this document places no requirements on the implementation.

- <sup>2</sup> In particular, the effects are undefined in the following cases:

(2.1) — for replacement functions (??), if the installed replacement function does not implement the semantics of the applicable *Required behavior*: paragraph.

- (2.2) — for handler functions (??, ??), if the installed handler function does not implement the semantics of the applicable *Required behavior*: paragraph
- (2.3) — for types used as template arguments when instantiating a template component, if the operations on the type do not implement the semantics of the applicable *Requirements* subclause (??, ??, ??, ??, ??). Operations on such types can report a failure by throwing an exception unless otherwise specified.
- (2.4) — if any replacement function or handler function or destructor operation exits via an exception, unless specifically allowed in the applicable *Required behavior*: paragraph.
- (2.5) — if an incomplete type (??) is used as a template argument when instantiating a template component, unless specifically allowed for that component.

#### 20.5.4.9 Function arguments

[res.on.arguments]

- <sup>1</sup> Each of the following applies to all arguments to functions defined in the C++ standard library, unless explicitly stated otherwise.
  - (1.1) — If an argument to a function has an invalid value (such as a value outside the domain of the function or a pointer invalid for its intended use), the behavior is undefined.
  - (1.2) — If a function argument is described as being an array, the pointer actually passed to the function shall have a value such that all address computations and accesses to objects (that would be valid if the pointer did point to the first element of such an array) are in fact valid.
  - (1.3) — If a function argument binds to an rvalue reference parameter, the implementation may assume that this parameter is a unique reference to this argument. [Note: If the parameter is a generic parameter of the form T&& and an lvalue of type A is bound, the argument binds to an lvalue reference (??) and thus is not covered by the previous sentence. —end note] [Note: If a program casts an lvalue to an xvalue while passing that lvalue to a library function (e.g., by calling the function with the argument `std::move(x)`), the program is effectively asking that function to treat that lvalue as a temporary object. The implementation is free to optimize away aliasing checks which might be needed if the argument was an lvalue. —end note]

#### 20.5.4.10 Library object access

[res.on.objects]

- <sup>1</sup> The behavior of a program is undefined if calls to standard library functions from different threads may introduce a data race. The conditions under which this may occur are specified in ???. [Note: Modifying an object of a standard library type that is shared between threads risks undefined behavior unless objects of that type are explicitly specified as being shareable without data races or the user supplies a locking mechanism. —end note]
- <sup>2</sup> If an object of a standard library type is accessed, and the beginning of the object's lifetime (??) does not happen before the access, or the access does not happen before the end of the object's lifetime, the behavior is undefined unless otherwise specified. [Note: This applies even to objects such as mutexes intended for thread synchronization. —end note]

#### 20.5.4.11 Requires paragraph

[res.on.required]

- <sup>1</sup> Violation of the preconditions specified in a function's *Requires*: paragraph results in undefined behavior unless the function's *Throws*: paragraph specifies throwing an exception when the precondition is violated.

**20.5.5 Conforming implementations**

[conforming]

**20.5.5.1 Overview**

[conforming.overview]

- <sup>1</sup> Subclause ?? describes the constraints upon, and latitude of, implementations of the C++ standard library.
- <sup>2</sup> An implementation's use of headers is discussed in ??, its use of macros in ??, non-member functions in ??, member functions in ??, data race avoidance in ??, access specifiers in ??, class derivation in ??, and exceptions in ??.

**20.5.5.2 Headers**

[res.on.headers]

- <sup>1</sup> A C++ header may include other C++ headers. A C++ header shall provide the declarations and definitions that appear in its synopsis. A C++ header shown in its synopsis as including other C++ headers shall provide the declarations and definitions that appear in the synopses of those other headers.
- <sup>2</sup> Certain types and macros are defined in more than one header. Every such entity shall be defined such that any header that defines it may be included after any other header that also defines it (??).
- <sup>3</sup> The C standard library headers (??) shall include only their corresponding C++ standard library header, as described in ??.

**20.5.5.3 Restrictions on macro definitions**

[res.on.macrodefinitions]

- <sup>1</sup> The names and global function signatures described in ?? are reserved to the implementation.
- <sup>2</sup> All object-like macros defined by the C standard library and described in this Clause as expanding to integral constant expressions are also suitable for use in #if preprocessing directives, unless explicitly stated otherwise.

**20.5.5.4 Non-member functions**

[global.functions]

- <sup>1</sup> It is unspecified whether any non-member functions in the C++ standard library are defined as inline (??).
- <sup>2</sup> A call to a non-member function signature described in ?? through ?? and ?? shall behave as if the implementation declared no additional non-member function signatures.<sup>185</sup>
- <sup>3</sup> An implementation shall not declare a non-member function signature with additional default arguments.
- <sup>4</sup> Unless otherwise specified, calls made by functions in the standard library to non-operator, non-member functions do not use functions from another namespace which are found through *argument-dependent name lookup* (??). [Note: The phrase “unless otherwise specified” applies to cases such as the swappable with requirements (??). The exception for overloaded operators allows argument-dependent lookup in cases like that of `ostream_iterator::operator=` (??):

*Effects:*

```
*out_stream << value;
if (delim != 0)
    *out_stream << delim;
return *this;
```

— end note ]

**20.5.5.5 Member functions**

[member.functions]

- <sup>1</sup> It is unspecified whether any member functions in the C++ standard library are defined as inline (??).
- <sup>2</sup> For a non-virtual member function described in the C++ standard library, an implementation may declare a different set of member function signatures, provided that any call to the member function that would

<sup>185)</sup> A valid C++ program always calls the expected library non-member function. An implementation may also define additional non-member functions that would otherwise not be called by a valid C++ program.

select an overload from the set of declarations described in this document behaves as if that overload were selected. [Note: For instance, an implementation may add parameters with default values, or replace a member function with default arguments with two or more member functions with equivalent behavior, or add additional signatures for a member function name. —end note]

#### 20.5.5.6 Constexpr functions and constructors

[**constexpr.functions**]

- <sup>1</sup> This document explicitly requires that certain standard library functions are **constexpr** (??). An implementation shall not declare any standard library function signature as **constexpr** except for those where it is explicitly required. Within any header that provides any non-defining declarations of **constexpr** functions or constructors an implementation shall provide corresponding definitions.

#### 20.5.5.7 Requirements for stable algorithms

[**algorithm.stable**]

- <sup>1</sup> When the requirements for an algorithm state that it is “stable” without further elaboration, it means:
  - (1.1) — For the *sort* algorithms the relative order of equivalent elements is preserved.
  - (1.2) — For the *remove* and *copy* algorithms the relative order of the elements that are not removed is preserved.
  - (1.3) — For the *merge* algorithms, for equivalent elements in the original two ranges, the elements from the first range (preserving their original order) precede the elements from the second range (preserving their original order).

#### 20.5.5.8 Reentrancy

[**reentrancy**]

- <sup>1</sup> Except where explicitly specified in this document, it is implementation-defined which functions in the C++ standard library may be recursively reentered.

#### 20.5.5.9 Data race avoidance

[**res.on.data.races**]

- <sup>1</sup> This subclause specifies requirements that implementations shall meet to prevent data races (??). Every standard library function shall meet each requirement unless otherwise specified. Implementations may prevent data races in cases other than those specified below.
- <sup>2</sup> A C++ standard library function shall not directly or indirectly access objects (??) accessible by threads other than the current thread unless the objects are accessed directly or indirectly via the function’s arguments, including **this**.
- <sup>3</sup> A C++ standard library function shall not directly or indirectly modify objects (??) accessible by threads other than the current thread unless the objects are accessed directly or indirectly via the function’s non-const arguments, including **this**.
- <sup>4</sup> [Note: This means, for example, that implementations can’t use a static object for internal purposes without synchronization because it could cause a data race even in programs that do not explicitly share objects between threads. —end note]
- <sup>5</sup> A C++ standard library function shall not access objects indirectly accessible via its arguments or via elements of its container arguments except by invoking functions required by its specification on those container elements.
- <sup>6</sup> Operations on iterators obtained by calling a standard library container or string member function may access the underlying container, but shall not modify it. [Note: In particular, container operations that invalidate iterators conflict with operations on iterators associated with that container. —end note]
- <sup>7</sup> Implementations may share their own internal objects between threads if the objects are not visible to users and are protected against data races.

- <sup>8</sup> Unless otherwise specified, C++ standard library functions shall perform all operations solely within the current thread if those operations have effects that are visible (??) to users.
- <sup>9</sup> [ *Note:* This allows implementations to parallelize operations if there are no visible side effects. — *end note* ]

#### 20.5.5.10 Protection within classes

[protection.within.classes]

- <sup>1</sup> It is unspecified whether any function signature or class described in ?? through ?? and ?? is a friend of another class in the C++ standard library.

#### 20.5.5.11 Derived classes

[derivation]

- <sup>1</sup> An implementation may derive any class in the C++ standard library from a class with a name reserved to the implementation.
- <sup>2</sup> Certain classes defined in the C++ standard library are required to be derived from other classes in the C++ standard library. An implementation may derive such a class directly from the required base or indirectly through a hierarchy of base classes with names reserved to the implementation.
- <sup>3</sup> In any case:
- (3.1) — Every base class described as `virtual` shall be virtual;
  - (3.2) — Every base class not specified as `virtual` shall not be virtual;
  - (3.3) — Unless explicitly stated otherwise, types with distinct names shall be distinct types.<sup>186</sup>
- <sup>4</sup> All types specified in the C++ standard library shall be non-final types unless otherwise specified.

#### 20.5.5.12 Restrictions on exception handling

[res.on.exception.handling]

- <sup>1</sup> Any of the functions defined in the C++ standard library can report a failure by throwing an exception of a type described in its *Throws:* paragraph, or of a type derived from a type named in the *Throws:* paragraph that would be caught by an exception handler for the base type.
- <sup>2</sup> Functions from the C standard library shall not throw exceptions<sup>187</sup> except when such a function calls a program-supplied function that throws an exception.<sup>188</sup>
- <sup>3</sup> Destructor operations defined in the C++ standard library shall not throw exceptions. Every destructor in the C++ standard library shall behave as if it had a non-throwing exception specification.
- <sup>4</sup> Functions defined in the C++ standard library that do not have a *Throws:* paragraph but do have a potentially-throwing exception specification may throw implementation-defined exceptions.<sup>189</sup> Implementations should report errors by throwing exceptions of or derived from the standard exception classes (??, ??, ??).
- <sup>5</sup> An implementation may strengthen the exception specification for a non-virtual function by adding a non-throwing exception specification.

#### 20.5.5.13 Restrictions on storage of pointers

[res.on.pointer.storage]

- <sup>1</sup> Objects constructed by the standard library that may hold a user-supplied pointer value or an integer of type `std::intptr_t` shall store such values in a traceable pointer location (??). [ *Note:* Other libraries are strongly encouraged to do the same, since not doing so may result in accidental use of pointers that are not

<sup>186</sup>) There is an implicit exception to this rule for types that are described as synonyms for basic integral types, such as `size_t` (??) and `streamoff` (??).

<sup>187</sup>) That is, the C library functions can all be treated as if they are marked `noexcept`. This allows implementations to make performance optimizations based on the absence of exceptions at runtime.

<sup>188</sup>) The functions `qsort()` and `bsearch()` (??) meet this condition.

<sup>189</sup>) In particular, they can report a failure to allocate storage by throwing an exception of type `bad_alloc`, or a class derived from `bad_alloc` (??).

safely derived. Libraries that store pointers outside the user's address space should make it appear that they are stored and retrieved from a traceable pointer location. — *end note*]

**20.5.5.14 Value of error codes**[**value.error.codes**]

- <sup>1</sup> Certain functions in the C++ standard library report errors via a `std::error_code` (??) object. That object's `category()` member shall return `std::system_category()` for errors originating from the operating system, or a reference to an implementation-defined `error_category` object for errors originating elsewhere. The implementation shall define the possible values of `value()` for each of these error categories. [*Example*: For operating systems that are based on POSIX, implementations should define the `std::system_category()` values as identical to the POSIX `errno` values, with additional values as defined by the operating system's documentation. Implementations for operating systems that are not based on POSIX should define values identical to the operating system's values. For errors that do not originate from the operating system, the implementation may provide enums for the associated values. — *end example*]

**20.5.5.15 Moved-from state of library types**[**lib.types.movedfrom**]

- <sup>1</sup> Objects of types defined in the C++ standard library may be moved from (??). Move operations may be explicitly specified or implicitly generated. Unless otherwise specified, such moved-from objects shall be placed in a valid but unspecified state.

# 21 Language support library

## [language.support]

### 21.1 General

[support.general]

- <sup>1</sup> This Clause describes the function signatures that are called implicitly, and the types of objects generated implicitly, during the execution of some C++ programs. It also describes the headers that declare these function signatures and define any related types.
- <sup>2</sup> The following subclauses describe common type definitions used throughout the library, characteristics of the predefined types, functions supporting start and termination of a C++ program, support for dynamic memory management, support for dynamic type identification, support for exception processing, support for initializer lists, and other runtime support, as summarized in Table ??.

Table 32 — Language support library summary

| Subclause                    | Header(s)                                        |
|------------------------------|--------------------------------------------------|
| ?? Common definitions        | <cstddef><br><cstdlib>                           |
| ?? Implementation properties | <limits><br><climits><br><cfloat>                |
| ?? Integer types             | <cstdint>                                        |
| ?? Start and termination     | <cstdlib>                                        |
| ?? Dynamic memory management | <new>                                            |
| ?? Type identification       | <typeinfo>                                       |
| ?? Exception handling        | <exception>                                      |
| ?? Initializer lists         | <initializer_list>                               |
| ?? Comparisons               | <compare>                                        |
| ?? Other runtime support     | <csignal><br><csetjmp><br><cstdarg><br><cstdlib> |

### 21.2 Common definitions

[support.types]

#### 21.2.1 Header <cstddef> synopsis

[cstddef.syn]

```
namespace std {
    using ptrdiff_t = see below;
    using size_t = see below;
    using max_align_t = see below;
    using nullptr_t = decltype(nullptr);

    enum class byte : unsigned char {};
}

// ??, byte type operations
template<class IntType>
constexpr byte& operator<<=(byte& b, IntType shift) noexcept;
```

```

template<class IntType>
    constexpr byte operator<<(byte b, IntType shift) noexcept;
template<class IntType>
    constexpr byte& operator>=(byte& b, IntType shift) noexcept;
template<class IntType>
    constexpr byte operator>>(byte b, IntType shift) noexcept;
constexpr byte& operator|=(byte& l, byte r) noexcept;
constexpr byte operator|(byte l, byte r) noexcept;
constexpr byte& operator&=(byte& l, byte r) noexcept;
constexpr byte operator&(byte l, byte r) noexcept;
constexpr byte& operator^=(byte& l, byte r) noexcept;
constexpr byte operator^(byte l, byte r) noexcept;
constexpr byte operator~(byte b) noexcept;
template<class IntType>
    constexpr IntType to_integer(byte b) noexcept;
}

#define NULL see below
#define offsetof(P, D) see below

```

- <sup>1</sup> The contents and meaning of the header <cstddef> are the same as the C standard library header <stddef.h>, except that it does not declare the type `wchar_t`, that it also declares the type `byte` and its associated operations (??), and as noted in ?? and ??.

div_t div(int numer, int denom);
ldiv_t div(long int numer, long int denom);           // see ???
lldiv_t div(long long int numer, long long int denom); // see ???
ldiv_t ldiv(long int numer, long int denom);
lldiv_t lldiv(long long int numer, long long int denom);
}

```

- <sup>1</sup> The contents and meaning of the header <cstdlib> are the same as the C standard library header <stdlib.h>, except that it does not declare the type `wchar_t`, and except as noted in ??, ??, ??, ??, ??, ??, ??, ??, and ??.  
[*Note*: Several functions have additional overloads in this document, but they have the same behavior as in the C standard library (??). — *end note*]

SEE ALSO: ISO C 7.22

### 21.2.3 Null pointers

[`support.types nullptr`]

- <sup>1</sup> The type `nullptr_t` is a synonym for the type of a `nullptr` expression, and it has the characteristics described in ?? and ???. [*Note*: Although `nullptr`'s address cannot be taken, the address of another `nullptr_t` object that is an lvalue can be taken. — *end note*]  
<sup>2</sup> The macro `NULL` is an implementation-defined null pointer constant.<sup>190</sup>

SEE ALSO: ISO C 7.19

### 21.2.4 Sizes, alignments, and offsets

[`support.types.layout`]

- <sup>1</sup> The macro `offsetof(type, member-designator)` has the same semantics as the corresponding macro in the C standard library header <stddef.h>, but accepts a restricted set of `type` arguments in this document. Use of the `offsetof` macro with a `type` other than a standard-layout class (??) is conditionally-supported.<sup>191</sup> The expression `offsetof(type, member-designator)` is never type-dependent (??) and it is value-dependent (??) if and only if `type` is dependent. The result of applying the `offsetof` macro to a static data member or a function member is undefined. No operation invoked by the `offsetof` macro shall throw an exception and `noexcept(offsetof(type, member-designator))` shall be `true`.  
<sup>2</sup> The type `ptrdiff_t` is an implementation-defined signed integer type that can hold the difference of two subscripts in an array object, as described in ??.  
<sup>3</sup> The type `size_t` is an implementation-defined unsigned integer type that is large enough to contain the size in bytes of any object (??).  
<sup>4</sup> [*Note*: It is recommended that implementations choose types for `ptrdiff_t` and `size_t` whose integer conversion ranks (??) are no greater than that of `signed long int` unless a larger size is necessary to contain all the possible values. — *end note*]

<sup>190</sup>) Possible definitions include 0 and `0L`, but not `(void*)0`.

<sup>191</sup>) Note that `offsetof` is required to work as specified even if unary `operator&` is overloaded for any of the types involved.

- <sup>5</sup> The type `max_align_t` is a trivial type whose alignment requirement is at least as great as that of every scalar type, and whose alignment requirement is supported in every context (??).

SEE ALSO: ISO C 7.19

### 21.2.5 byte type operations

[`support.types.byteops`]

```
template<class IntType>
constexpr byte& operator<<=(byte& b, IntType shift) noexcept;
```

<sup>1</sup> *Remarks:* This function shall not participate in overload resolution unless `is_integral_v<IntType>` is true.

<sup>2</sup> *Effects:* Equivalent to: `return b = b << shift;`

```
template<class IntType>
constexpr byte operator<<(byte b, IntType shift) noexcept;
```

<sup>3</sup> *Remarks:* This function shall not participate in overload resolution unless `is_integral_v<IntType>` is true.

<sup>4</sup> *Effects:* Equivalent to:

```
    return static_cast<byte>(static_cast<unsigned char>(
        static_cast<unsigned int>(b) << shift));
```

```
template<class IntType>
constexpr byte& operator>=(byte& b, IntType shift) noexcept;
```

<sup>5</sup> *Remarks:* This function shall not participate in overload resolution unless `is_integral_v<IntType>` is true.

<sup>6</sup> *Effects:* Equivalent to: `return b >> shift;`

```
template<class IntType>
constexpr byte operator>>(byte b, IntType shift) noexcept;
```

<sup>7</sup> *Remarks:* This function shall not participate in overload resolution unless `is_integral_v<IntType>` is true.

<sup>8</sup> *Effects:* Equivalent to:

```
    return static_cast<byte>(static_cast<unsigned char>(
        static_cast<unsigned int>(b) >> shift));
```

```
constexpr byte& operator|=(byte& l, byte r) noexcept;
```

<sup>9</sup> *Effects:* Equivalent to: `return l = l | r;`

```
constexpr byte operator|(byte l, byte r) noexcept;
```

<sup>10</sup> *Effects:* Equivalent to:

```
    return static_cast<byte>(static_cast<unsigned char>(static_cast<unsigned int>(l) |
        static_cast<unsigned int>(r)));
```

```
constexpr byte& operator&=(byte& l, byte r) noexcept;
```

<sup>11</sup> *Effects:* Equivalent to: `return l = l & r;`

```
constexpr byte operator&(byte l, byte r) noexcept;
```

<sup>12</sup> *Effects:* Equivalent to:

```

        return static_cast<byte>(static_cast<unsigned char>(static_cast<unsigned int>(l) &
   static_cast<unsigned int>(r)));
}

constexpr byte& operator^=(byte& l, byte r) noexcept;

13   Effects: Equivalent to: return l = l ^ r;

constexpr byte operator^(byte l, byte r) noexcept;

14   Effects: Equivalent to:

        return static_cast<byte>(static_cast<unsigned char>(static_cast<unsigned int>(l) ^
   static_cast<unsigned int>(r)));
}

constexpr byte operator~(byte b) noexcept;

15   Effects: Equivalent to:

        return static_cast<byte>(static_cast<unsigned char>(
            ~static_cast<unsigned int>(b)));
}

template<class IntType>
constexpr IntType to_integer(byte b) noexcept;

16   Remarks: This function shall not participate in overload resolution unless is_integral_v<IntType> is
true.

17   Effects: Equivalent to: return static_cast<IntType>(b);

```

## 21.3 Implementation properties

[support.limits]

### 21.3.1 General

[support.limits.general]

- <sup>1</sup> The headers `<limits>` (??), `<climits>` (??), and `<cfloat>` (??) supply characteristics of implementation-dependent arithmetic types (??).

### 21.3.2 Header `<limits>` synopsis

[limits.syn]

```

namespace std {
    // ??, floating-point type properties
    enum float_round_style;
    enum float_denorm_style;

    // ??, class template numeric_limits
    template<class T> class numeric_limits;

    template<> class numeric_limits<bool>;

    template<> class numeric_limits<char>;
    template<> class numeric_limits<signed char>;
    template<> class numeric_limits<unsigned char>;
    template<> class numeric_limits<char16_t>;
    template<> class numeric_limits<char32_t>;
    template<> class numeric_limits<wchar_t>;

    template<> class numeric_limits<short>;
    template<> class numeric_limits<int>;
    template<> class numeric_limits<long>;
}

```

```

template<> class numeric_limits<long long>;
template<> class numeric_limits<unsigned short>;
template<> class numeric_limits<unsigned int>;
template<> class numeric_limits<unsigned long>;
template<> class numeric_limits<unsigned long long>

template<> class numeric_limits<float>;
template<> class numeric_limits<double>;
template<> class numeric_limits<long double>;
}

```

### 21.3.3 Floating-point type properties

[fp.style]

#### 21.3.3.1 Type float\_round\_style

[round.style]

```

namespace std {
    enum float_round_style {
        round_ineterminate      = -1,
        round_toward_zero       = 0,
        round_to_nearest         = 1,
        round_toward_infinity   = 2,
        round_toward_neg_infinity = 3
    };
}

```

<sup>1</sup> The rounding mode for floating-point arithmetic is characterized by the values:

- (1.1) — `round_ineterminate` if the rounding style is indeterminable
- (1.2) — `round_toward_zero` if the rounding style is toward zero
- (1.3) — `round_to_nearest` if the rounding style is to the nearest representable value
- (1.4) — `round_toward_infinity` if the rounding style is toward infinity
- (1.5) — `round_toward_neg_infinity` if the rounding style is toward negative infinity

#### 21.3.3.2 Type float\_denorm\_style

[denorm.style]

```

namespace std {
    enum float_denorm_style {
        denorm_ineterminate = -1,
        denorm_absent = 0,
        denorm_present = 1
    };
}

```

<sup>1</sup> The presence or absence of subnormal numbers (variable number of exponent bits) is characterized by the values:

- (1.1) — `denorm_ineterminate` if it cannot be determined whether or not the type allows subnormal values
- (1.2) — `denorm_absent` if the type does not allow subnormal values
- (1.3) — `denorm_present` if the type does allow subnormal values

### 21.3.4 Class template numeric\_limits

[**numeric.limits**]

- <sup>1</sup> The `numeric_limits` class template provides a C++ program with information about various properties of the implementation's representation of the arithmetic types.

```
namespace std {
    template<class T> class numeric_limits {
        public:
            static constexpr bool is_specialized = false;
            static constexpr T min() noexcept { return T(); }
            static constexpr T max() noexcept { return T(); }
            static constexpr T lowest() noexcept { return T(); }

            static constexpr int digits = 0;
            static constexpr int digits10 = 0;
            static constexpr int max_digits10 = 0;
            static constexpr bool is_signed = false;
            static constexpr bool is_integer = false;
            static constexpr bool is_exact = false;
            static constexpr int radix = 0;
            static constexpr T epsilon() noexcept { return T(); }
            static constexpr T round_error() noexcept { return T(); }

            static constexpr int min_exponent = 0;
            static constexpr int min_exponent10 = 0;
            static constexpr int max_exponent = 0;
            static constexpr int max_exponent10 = 0;

            static constexpr bool has_infinity = false;
            static constexpr bool has_quiet_NaN = false;
            static constexpr bool has_signaling_NaN = false;
            static constexpr float_denorm_style has_denorm = denorm_absent;
            static constexpr bool has_denorm_loss = false;
            static constexpr T infinity() noexcept { return T(); }
            static constexpr T quiet_NaN() noexcept { return T(); }
            static constexpr T signaling_NaN() noexcept { return T(); }
            static constexpr T denorm_min() noexcept { return T(); }

            static constexpr bool is_iec559 = false;
            static constexpr bool is_bounded = false;
            static constexpr bool is_modulo = false;

            static constexpr bool traps = false;
            static constexpr bool tinyness_before = false;
            static constexpr float_round_style round_style = round_toward_zero;
    };
}

template<class T> class numeric_limits<const T>;
template<class T> class numeric_limits<volatile T>;
template<class T> class numeric_limits<const volatile T>;
}
```

- <sup>2</sup> For all members declared `static constexpr` in the `numeric_limits` template, specializations shall define these values in such a way that they are usable as constant expressions.
- <sup>3</sup> The default `numeric_limits<T>` template shall have all members, but with 0 or `false` values.
- <sup>4</sup> Specializations shall be provided for each arithmetic type, both floating-point and integer, including `bool`. The member `is_specialized` shall be `true` for all such specializations of `numeric_limits`.
- <sup>5</sup> The value of each member of a specialization of `numeric_limits` on a cv-qualified type `cv T` shall be equal to the value of the corresponding member of the specialization on the unqualified type `T`.
- <sup>6</sup> Non-arithmetic standard types, such as `complex<T>` (??), shall not have specializations.

#### 21.3.4.1 `numeric_limits` members

[`numeric_limits.members`]

- <sup>1</sup> Each member function defined in this subclause is signal-safe (??).

`static constexpr T min() noexcept;`

- <sup>2</sup> Minimum finite value.<sup>192</sup>

<sup>3</sup> For floating types with subnormal numbers, returns the minimum positive normalized value.

<sup>4</sup> Meaningful for all specializations in which `is_bounded != false`, or `is_bounded == false && is_signed == false`.

`static constexpr T max() noexcept;`

- <sup>5</sup> Maximum finite value.<sup>193</sup>

<sup>6</sup> Meaningful for all specializations in which `is_bounded != false`.

`static constexpr T lowest() noexcept;`

- <sup>7</sup> A finite value `x` such that there is no other finite value `y` where `y < x`.<sup>194</sup>

<sup>8</sup> Meaningful for all specializations in which `is_bounded != false`.

`static constexpr int digits;`

- <sup>9</sup> Number of `radix` digits that can be represented without change.

<sup>10</sup> For integer types, the number of non-sign bits in the representation.

<sup>11</sup> For floating-point types, the number of `radix` digits in the mantissa.<sup>195</sup>

`static constexpr int digits10;`

- <sup>12</sup> Number of base 10 digits that can be represented without change.<sup>196</sup>

<sup>13</sup> Meaningful for all specializations in which `is_bounded != false`.

`static constexpr int max_digits10;`

- <sup>14</sup> Number of base 10 digits required to ensure that values which differ are always differentiated.

<sup>15</sup> Meaningful for all floating-point types.

<sup>192)</sup> Equivalent to `CHAR_MIN`, `SHRT_MIN`, `FLT_MIN`, `DBL_MIN`, etc.

<sup>193)</sup> Equivalent to `CHAR_MAX`, `SHRT_MAX`, `FLT_MAX`, `DBL_MAX`, etc.

<sup>194)</sup> `lowest()` is necessary because not all floating-point representations have a smallest (most negative) value that is the negative of the largest (most positive) finite value.

<sup>195)</sup> Equivalent to `FLT_MANT_DIG`, `DBL_MANT_DIG`, `LDBL_MANT_DIG`.

<sup>196)</sup> Equivalent to `FLT_DIG`, `DBL_DIG`, `LDBL_DIG`.

```

static constexpr bool is_signed;
16   true if the type is signed.

17 Meaningful for all specializations.

static constexpr bool is_integer;
18   true if the type is integer.

19 Meaningful for all specializations.

static constexpr bool is_exact;
20   true if the type uses an exact representation. All integer types are exact, but not all exact types are
      integer. For example, rational and fixed-exponent representations are exact but not integer.

21 Meaningful for all specializations.

static constexpr int radix;
22   For floating types, specifies the base or radix of the exponent representation (often 2).197
23   For integer types, specifies the base of the representation.198
24 Meaningful for all specializations.

static constexpr T epsilon() noexcept;
25   Machine epsilon: the difference between 1 and the least value greater than 1 that is representable.199
26 Meaningful for all floating-point types.

static constexpr T round_error() noexcept;
27   Measure of the maximum rounding error.200

static constexpr int min_exponent;
28   Minimum negative integer such that radix raised to the power of one less than that integer is a
      normalized floating-point number.201
29 Meaningful for all floating-point types.

static constexpr int min_exponent10;
30   Minimum negative integer such that 10 raised to that power is in the range of normalized floating-point
      numbers.202
31 Meaningful for all floating-point types.

static constexpr int max_exponent;
32   Maximum positive integer such that radix raised to the power one less than that integer is a representable
      finite floating-point number.203
33 Meaningful for all floating-point types.

```

<sup>197</sup>) Equivalent to `FLT_RADIX`.

<sup>198</sup>) Distinguishes types with bases other than 2 (e.g. BCD).

<sup>199</sup>) Equivalent to `FLT_EPSILON`, `DBL_EPSILON`, `LDBL_EPSILON`.

<sup>200</sup>) Rounding error is described in LIA-1 Section 5.2.4 and Annex C Rationale Section C.5.2.4 — Rounding and rounding constants.

<sup>201</sup>) Equivalent to `FLT_MIN_EXP`, `DBL_MIN_EXP`, `LDBL_MIN_EXP`.

<sup>202</sup>) Equivalent to `FLT_MIN_10_EXP`, `DBL_MIN_10_EXP`, `LDBL_MIN_10_EXP`.

<sup>203</sup>) Equivalent to `FLT_MAX_EXP`, `DBL_MAX_EXP`, `LDBL_MAX_EXP`.

```

static constexpr int max_exponent10;

34     Maximum positive integer such that 10 raised to that power is in the range of representable finite
          floating-point numbers.204

35     Meaningful for all floating-point types.

static constexpr bool has_infinity;

36     true if the type has a representation for positive infinity.

37     Meaningful for all floating-point types.

38     Shall be true for all specializations in which is_iec559 != false.

static constexpr bool has_quiet_NaN;

39     true if the type has a representation for a quiet (non-signaling) “Not a Number”.205

40     Meaningful for all floating-point types.

41     Shall be true for all specializations in which is_iec559 != false.

static constexpr bool has_signaling_NaN;

42     true if the type has a representation for a signaling “Not a Number”.206

43     Meaningful for all floating-point types.

44     Shall be true for all specializations in which is_iec559 != false.

static constexpr float_denorm_style has_denorm;

45     denorm_present if the type allows subnormal values (variable number of exponent bits)207, denorm-
          absent if the type does not allow subnormal values, and denorm_ineterminate if it is indeterminate
          at compile time whether the type allows subnormal values.

46     Meaningful for all floating-point types.

static constexpr bool has_denorm_loss;

47     true if loss of accuracy is detected as a denormalization loss, rather than as an inexact result.208

static constexpr T infinity() noexcept;

48     Representation of positive infinity, if available.209

49     Meaningful for all specializations for which has_infinity != false. Required in specializations for
          which is_iec559 != false.

static constexpr T quiet_NaN() noexcept;

50     Representation of a quiet “Not a Number”, if available.210

51     Meaningful for all specializations for which has_quiet_NaN != false. Required in specializations for
          which is_iec559 != false.

```

<sup>204</sup>) Equivalent to FLT\_MAX\_10\_EXP, DBL\_MAX\_10\_EXP, LDBL\_MAX\_10\_EXP.

<sup>205</sup>) Required by LIA-1.

<sup>206</sup>) Required by LIA-1.

<sup>207</sup>) Required by LIA-1.

<sup>208</sup>) See ISO/IEC/IEEE 60559.

<sup>209</sup>) Required by LIA-1.

<sup>210</sup>) Required by LIA-1.

```

static constexpr T signaling_NaN() noexcept;
52   Representation of a signaling “Not a Number”, if available.211
53   Meaningful for all specializations for which has_signaling_NaN != false. Required in specializations
      for which is_iec559 != false.
      
```

```

static constexpr T denorm_min() noexcept;
54   Minimum positive subnormal value.212
55   Meaningful for all floating-point types.
56   In specializations for which has_denorm == false, returns the minimum positive normalized value.
      
```

```

static constexpr bool is_iec559;
57   true if and only if the type adheres to ISO/IEC/IEEE 60559.213
58   Meaningful for all floating-point types.
      
```

```

static constexpr bool is_bounded;
59   true if the set of values representable by the type is finite.214 [Note: All fundamental types (??) are
      bounded. This member would be false for arbitrary precision types. —end note]
60   Meaningful for all specializations.
      
```

```

static constexpr bool is_modulo;
61   true if the type is modulo.215 A type is modulo if, for any operation involving +, -, or * on values of
      that type whose result would fall outside the range [min(), max()], the value returned differs from
      the true value by an integer multiple of max() - min() + 1.
62   [Example: is_modulo is false for signed integer types (??) unless an implementation, as an extension
      to this document, defines signed integer overflow to wrap. —end example]
63   Meaningful for all specializations.
      
```

```

static constexpr bool traps;
64   true if, at program startup, there exists a value of the type that would cause an arithmetic operation
      using that value to trap.216
65   Meaningful for all specializations.
      
```

```

static constexpr bool tinyness_before;
66   true if tinyness is detected before rounding.217
67   Meaningful for all floating-point types.
      
```

```

static constexpr float_round_style round_style;
68   The rounding style for the type.218
      
```

<sup>211)</sup> Required by LIA-1.

<sup>212)</sup> Required by LIA-1.

<sup>213)</sup> ISO/IEC/IEEE 60559:2011 is the same as IEEE 754-2008.

<sup>214)</sup> Required by LIA-1.

<sup>215)</sup> Required by LIA-1.

<sup>216)</sup> Required by LIA-1.

<sup>217)</sup> Refer to ISO/IEC/IEEE 60559. Required by LIA-1.

<sup>218)</sup> Equivalent to `FLT_ROUNDS`. Required by LIA-1.

69        Meaningful for all floating-point types. Specializations for integer types shall return `round_toward_zero`.

### 21.3.4.2 `numeric_limits` specializations

[`numeric.special`]

<sup>1</sup> All members shall be provided for all specializations. However, many values are only required to be meaningful under certain conditions (for example, `epsilon()` is only meaningful if `is_integer` is `false`). Any value that is not “meaningful” shall be set to 0 or `false`.

<sup>2</sup> [*Example*:

```
namespace std {
    template<> class numeric_limits<float> {
public:
    static constexpr bool is_specialized = true;

    static constexpr float min() noexcept { return 1.17549435E-38F; }
    static constexpr float max() noexcept { return 3.40282347E+38F; }
    static constexpr float lowest() noexcept { return -3.40282347E+38F; }

    static constexpr int digits    = 24;
    static constexpr int digits10 =  6;
    static constexpr int max_digits10 =  9;

    static constexpr bool is_signed   = true;
    static constexpr bool is_integer = false;
    static constexpr bool is_exact    = false;

    static constexpr int radix = 2;
    static constexpr float epsilon() noexcept      { return 1.19209290E-07F; }
    static constexpr float round_error() noexcept { return 0.5F; }

    static constexpr int min_exponent    = -125;
    static constexpr int min_exponent10 = - 37;
    static constexpr int max_exponent    = +128;
    static constexpr int max_exponent10 = + 38;

    static constexpr bool has_infinity           = true;
    static constexpr bool has_quiet_NaN          = true;
    static constexpr bool has_signaling_NaN       = true;
    static constexpr float_denorm_style has_denorm = denorm_absent;
    static constexpr bool has_denorm_loss         = false;

    static constexpr float infinity()      noexcept { return value; }
    static constexpr float quiet_NaN()     noexcept { return value; }
    static constexpr float signaling_NaN()  noexcept { return value; }
    static constexpr float denorm_min()    noexcept { return min(); }

    static constexpr bool is_iec559   = true;
    static constexpr bool is_bounded = true;
    static constexpr bool is_modulo  = false;
    static constexpr bool traps      = true;
```

```

    static constexpr bool tinyness_before = true;

    static constexpr float_round_style round_style = round_to_nearest;
};

}

— end example]

```

- 3 The specialization for `bool` shall be provided as follows:

```

namespace std {

    template<> class numeric_limits<bool> {
public:
    static constexpr bool is_specialized = true;
    static constexpr bool min() noexcept { return false; }
    static constexpr bool max() noexcept { return true; }
    static constexpr bool lowest() noexcept { return false; }

    static constexpr int digits = 1;
    static constexpr int digits10 = 0;
    static constexpr int max_digits10 = 0;

    static constexpr bool is_signed = false;
    static constexpr bool is_integer = true;
    static constexpr bool is_exact = true;
    static constexpr int radix = 2;
    static constexpr bool epsilon() noexcept { return 0; }
    static constexpr bool round_error() noexcept { return 0; }

    static constexpr int min_exponent = 0;
    static constexpr int min_exponent10 = 0;
    static constexpr int max_exponent = 0;
    static constexpr int max_exponent10 = 0;

    static constexpr bool has_infinity = false;
    static constexpr bool has_quiet_NaN = false;
    static constexpr bool has_signaling_NaN = false;
    static constexpr float_denorm_style has_denorm = denorm_absent;
    static constexpr bool has_denorm_loss = false;
    static constexpr bool infinity() noexcept { return 0; }
    static constexpr bool quiet_NaN() noexcept { return 0; }
    static constexpr bool signaling_NaN() noexcept { return 0; }
    static constexpr bool denorm_min() noexcept { return 0; }

    static constexpr bool is_iec559 = false;
    static constexpr bool is_bounded = true;
    static constexpr bool is_modulo = false;

    static constexpr bool traps = false;
    static constexpr bool tinyness_before = false;
    static constexpr float_round_style round_style = round_toward_zero;
}

```

```
    };
}
```

## 21.4 Integer types

[cstdint]

### 21.4.1 Header <cstdint> synopsis

[cstdint.syn]

```
namespace std {
    using int8_t      = signed integer type; // optional
    using int16_t     = signed integer type; // optional
    using int32_t     = signed integer type; // optional
    using int64_t     = signed integer type; // optional

    using int_fast8_t = signed integer type;
    using int_fast16_t= signed integer type;
    using int_fast32_t= signed integer type;
    using int_fast64_t= signed integer type;

    using int_least8_t = signed integer type;
    using int_least16_t= signed integer type;
    using int_least32_t= signed integer type;
    using int_least64_t= signed integer type;

    using intmax_t    = signed integer type;
    using intptr_t    = signed integer type; // optional

    using uint8_t     = unsigned integer type; // optional
    using uint16_t    = unsigned integer type; // optional
    using uint32_t    = unsigned integer type; // optional
    using uint64_t    = unsigned integer type; // optional
```

```

using uint_fast8_t    = unsigned integer type;
using uint_fast16_t   = unsigned integer type;
using uint_fast32_t   = unsigned integer type;
using uint_fast64_t   = unsigned integer type;

using uint_least8_t   = unsigned integer type;
using uint_least16_t  = unsigned integer type;
using uint_least32_t  = unsigned integer type;
using uint_least64_t  = unsigned integer type;

using uintmax_t       = unsigned integer type;
using uintptr_t       = unsigned integer type; // optional
}

```

- <sup>1</sup> The header also defines numerous macros of the form:

```

INT_{FAST LEAST}{8 16 32 64}_MIN
[U]INT_{FAST LEAST}{8 16 32 64}_MAX
INT{MAX PTR}_MIN
[U]INT{MAX PTR}_MAX
{PTRDIFF SIG_ATOMIC WCHAR WINT}_{_MAX _MIN}
SIZE_MAX

```

plus function macros of the form:

```
[U]INT{8 16 32 64 MAX}_C
```

- <sup>2</sup> The header defines all types and macros the same as the C standard library header `<stdint.h>`.

SEE ALSO: ISO C 7.20

## 21.5 Start and termination

[[support.start.term](#)]

- <sup>1</sup> [*Note*: The header `<cstdlib>` (??) declares the functions described in this subclause. — *end note*]

```
[[noreturn]] void _Exit(int status) noexcept;
```

- <sup>2</sup> *Effects*: This function has the semantics specified in the C standard library.

- <sup>3</sup> *Remarks*: The program is terminated without executing destructors for objects of automatic, thread, or static storage duration and without calling functions passed to `atexit()` (??). The function `_Exit` is signal-safe (??).

```
[[noreturn]] void abort() noexcept;
```

- <sup>4</sup> *Effects*: This function has the semantics specified in the C standard library.

- <sup>5</sup> *Remarks*: The program is terminated without executing destructors for objects of automatic, thread, or static storage duration and without calling functions passed to `atexit()` (??). The function `abort` is signal-safe (??).

```
int atexit(c-atexit-handler* f) noexcept;
int atexit(atexit-handler* f) noexcept;
```

- <sup>6</sup> *Effects*: The `atexit()` functions register the function pointed to by `f` to be called without arguments at normal program termination. It is unspecified whether a call to `atexit()` that does not happen before (??) a call to `exit()` will succeed. [*Note*: The `atexit()` functions do not introduce a data race (??). — *end note*]

7        *Implementation limits:* The implementation shall support the registration of at least 32 functions.

8        *Returns:* The `atexit()` function returns zero if the registration succeeds, nonzero if it fails.

9        `[[noreturn]] void exit(int status);`

9        *Effects:*

- (9.1) — First, objects with thread storage duration and associated with the current thread are destroyed. Next, objects with static storage duration are destroyed and functions registered by calling `atexit` are called.<sup>219</sup> See ?? for the order of destructions and calls. (Automatic objects are not destroyed as a result of calling `exit()`).<sup>220</sup>  
If control leaves a registered function called by `exit` because the function does not provide a handler for a thrown exception, `std::terminate()` shall be called (??).
- (9.2) — Next, all open C streams (as mediated by the function signatures declared in `<cstdio>`) with unwritten buffered data are flushed, all open C streams are closed, and all files created by calling `tmpfile()` are removed.
- (9.3) — Finally, control is returned to the host environment. If `status` is zero or `EXIT_SUCCESS`, an implementation-defined form of the status *successful termination* is returned. If `status` is `EXIT_FAILURE`, an implementation-defined form of the status *unsuccessful termination* is returned. Otherwise the status returned is implementation-defined.<sup>221</sup>

```
int at_quick_exit(c-atexit-handler* f) noexcept;
int at_quick_exit(atexit-handler* f) noexcept;
```

10      *Effects:* The `at_quick_exit()` functions register the function pointed to by `f` to be called without arguments when `quick_exit` is called. It is unspecified whether a call to `at_quick_exit()` that does not happen before (??) all calls to `quick_exit` will succeed. [Note: The `at_quick_exit()` functions do not introduce a data race (??). —end note] [Note: The order of registration may be indeterminate if `at_quick_exit` was called from more than one thread. —end note] [Note: The `at_quick_exit` registrations are distinct from the `atexit` registrations, and applications may need to call both registration functions with the same argument. —end note]

11      *Implementation limits:* The implementation shall support the registration of at least 32 functions.

12      *Returns:* Zero if the registration succeeds, nonzero if it fails.

13      `[[noreturn]] void quick_exit(int status) noexcept;`

13      *Effects:* Functions registered by calls to `at_quick_exit` are called in the reverse order of their registration, except that a function shall be called after any previously registered functions that had already been called at the time it was registered. Objects shall not be destroyed as a result of calling `quick_exit`. If control leaves a registered function called by `quick_exit` because the function does not provide a handler for a thrown exception, `std::terminate()` shall be called. [Note: A function registered via `at_quick_exit` is invoked by the thread that calls `quick_exit`, which can be a different thread than the one that registered it, so registered functions should not rely on the identity of objects

---

219) A function is called for every time it is registered.

220) Objects with automatic storage duration are all destroyed in a program whose `main` function (??) contains no automatic objects and executes the call to `exit()`. Control can be transferred directly to such a `main` function by throwing an exception that is caught in `main`.

221) The macros `EXIT_FAILURE` and `EXIT_SUCCESS` are defined in `<cstdlib>`.

with thread storage duration. — *end note*] After calling registered functions, `quick_exit` shall call `_Exit(status)`.

<sup>14</sup> *Remarks:* The function `quick_exit` is signal-safe (??) when the functions registered with `at_quick_exit` are.

## 21.6 Dynamic memory management

[**support.dynamic**]

- <sup>1</sup> The header `<new>` defines several functions that manage the allocation of dynamic storage in a program. It also defines components for reporting storage management errors.

### 21.6.1 Header `<new>` synopsis

[**new.syn**]

```
namespace std {
    class bad_alloc;
    class bad_array_new_length;

    enum class align_val_t : size_t {};

    struct nothrow_t { explicit nothrow_t() = default; };
    extern const nothrow_t nothrow;

    using new_handler = void (*)();
    new_handler get_new_handler() noexcept;
    new_handler set_new_handler(new_handler new_p) noexcept;

    // ??, pointer optimization barrier
    template<class T> [[nodiscard]] constexpr T* launder(T* p) noexcept;

    // ??, hardware interference size
    inline constexpr size_t hardware_destructive_interference_size = implementation-defined;
    inline constexpr size_t hardware_constructive_interference_size = implementation-defined;
}

[[nodiscard]] void* operator new(std::size_t size);
[[nodiscard]] void* operator new(std::size_t size, std::align_val_t alignment);
[[nodiscard]] void* operator new(std::size_t size, const std::nothrow_t&) noexcept;
[[nodiscard]] void* operator new(std::size_t size, std::align_val_t alignment,
                               const std::nothrow_t&) noexcept;

void operator delete(void* ptr) noexcept;
void operator delete(void* ptr, std::size_t size) noexcept;
void operator delete(void* ptr, std::align_val_t alignment) noexcept;
void operator delete(void* ptr, std::size_t size, std::align_val_t alignment) noexcept;
void operator delete(void* ptr, const std::nothrow_t&) noexcept;
void operator delete(void* ptr, std::align_val_t alignment, const std::nothrow_t&) noexcept;

[[nodiscard]] void* operator new[](std::size_t size);
[[nodiscard]] void* operator new[](std::size_t size, std::align_val_t alignment);
[[nodiscard]] void* operator new[](std::size_t size, const std::nothrow_t&) noexcept;
```

```
[[nodiscard]] void* operator new[](std::size_t size, std::align_val_t alignment,
                                const std::nothrow_t&) noexcept;

void operator delete[](void* ptr) noexcept;
void operator delete[](void* ptr, std::size_t size) noexcept;
void operator delete[](void* ptr, std::align_val_t alignment) noexcept;
void operator delete[](void* ptr, std::size_t size, std::align_val_t alignment) noexcept;
void operator delete[](void* ptr, const std::nothrow_t&) noexcept;
void operator delete[](void* ptr, std::align_val_t alignment, const std::nothrow_t&) noexcept;

[[nodiscard]] void* operator new (std::size_t size, void* ptr) noexcept;
[[nodiscard]] void* operator new[](std::size_t size, void* ptr) noexcept;
void operator delete (void* ptr, void*) noexcept;
void operator delete[](void* ptr, void*) noexcept;
```

## 21.6.2 Storage allocation and deallocation

[new.delete]

- <sup>1</sup> Except where otherwise specified, the provisions of ?? apply to the library versions of `operator new` and `operator delete`. If the value of an alignment argument passed to any of these functions is not a valid alignment value, the behavior is undefined.

### 21.6.2.1 Single-object forms

[new.delete.single]

```
[[nodiscard]] void* operator new(std::size_t size);
[[nodiscard]] void* operator new(std::size_t size, std::align_val_t alignment);
```

- <sup>1</sup> *Effects:* The allocation functions (??) called by a *new-expression* (??) to allocate `size` bytes of storage. The second form is called for a type with new-extended alignment, and allocates storage with the specified alignment. The first form is called otherwise, and allocates storage suitably aligned to represent any object of that size provided the object's type does not have new-extended alignment.
- <sup>2</sup> *Replaceable:* A C++ program may define functions with either of these function signatures, and thereby displace the default versions defined by the C++ standard library.
- <sup>3</sup> *Required behavior:* Return a non-null pointer to suitably aligned storage (??), or else throw a `bad_alloc` exception. This requirement is binding on any replacement versions of these functions.
- <sup>4</sup> *Default behavior:*
- (4.1) — Executes a loop: Within the loop, the function first attempts to allocate the requested storage. Whether the attempt involves a call to the C standard library functions `malloc` or `aligned_alloc` is unspecified.
  - (4.2) — Returns a pointer to the allocated storage if the attempt is successful. Otherwise, if the current `new_handler` (??) is a null pointer value, throws `bad_alloc`.
  - (4.3) — Otherwise, the function calls the current `new_handler` function (??). If the called function returns, the loop repeats.
  - (4.4) — The loop terminates when an attempt to allocate the requested storage is successful or when a called `new_handler` function does not return.

```
[[nodiscard]] void* operator new(std::size_t size, const std::nothrow_t&) noexcept;
```

```
[[nodiscard]] void* operator new(std::size_t size, std::align_val_t alignment,
                               const std::nothrow_t&) noexcept;
```

5     *Effects:* Same as above, except that these are called by a placement version of a *new-expression* when a C++ program prefers a null pointer result as an error indication, instead of a `bad_alloc` exception.

6     *Replaceable:* A C++ program may define functions with either of these function signatures, and thereby displace the default versions defined by the C++ standard library.

7     *Required behavior:* Return a non-null pointer to suitably aligned storage (??), or else return a null pointer. Each of these `nothrow` versions of `operator new` returns a pointer obtained as if acquired from the (possibly replaced) corresponding non-placement function. This requirement is binding on any replacement versions of these functions.

8     *Default behavior:* Calls `operator new(size)`, or `operator new(size, alignment)`, respectively. If the call returns normally, returns the result of that call. Otherwise, returns a null pointer.

9     [*Example:*

```
T* p1 = new T;           // throws bad_alloc if it fails
T* p2 = new(nothrow) T; // returns nullptr if it fails
— end example]
```

```
void operator delete(void* ptr) noexcept;
void operator delete(void* ptr, std::size_t size) noexcept;
void operator delete(void* ptr, std::align_val_t alignment) noexcept;
void operator delete(void* ptr, std::size_t size, std::align_val_t alignment) noexcept;
```

10    *Effects:* The deallocation functions (??) called by a *delete-expression* (??) to render the value of `ptr` invalid.

11    *Replaceable:* A C++ program may define functions with any of these function signatures, and thereby displace the default versions defined by the C++ standard library. If a function without a `size` parameter is defined, the program should also define the corresponding function with a `size` parameter. If a function with a `size` parameter is defined, the program shall also define the corresponding version without the `size` parameter. [*Note:* The default behavior below may change in the future, which will require replacing both deallocation functions when replacing the allocation function. — *end note*]

12    *Requires:* `ptr` shall be a null pointer or its value shall represent the address of a block of memory allocated by an earlier call to a (possibly replaced) `operator new(std::size_t)` or `operator new(std::size_t, std::align_val_t)` which has not been invalidated by an intervening call to `operator delete`.

13    *Requires:* If an implementation has strict pointer safety (??) then `ptr` shall be a safely-derived pointer.

14    *Requires:* If the `alignment` parameter is not present, `ptr` shall have been returned by an allocation function without an `alignment` parameter. If present, the `alignment` argument shall equal the `alignment` argument passed to the allocation function that returned `ptr`. If present, the `size` argument shall equal the `size` argument passed to the allocation function that returned `ptr`.

15    *Required behavior:* A call to an `operator delete` with a `size` parameter may be changed to a call to the corresponding `operator delete` without a `size` parameter, without affecting memory allocation.

[*Note:* A conforming implementation is for `operator delete(void* ptr, std::size_t size)` to simply call `operator delete(ptr)`. — *end note*]

- 16     *Default behavior:* The functions that have a `size` parameter forward their other parameters to the corresponding function without a `size` parameter. [ *Note:* See the note in the above *Replaceable*: paragraph. — *end note* ]
- 17     *Default behavior:* If `ptr` is null, does nothing. Otherwise, reclaims the storage allocated by the earlier call to `operator new`.
- 18     *Remarks:* It is unspecified under what conditions part or all of such reclaimed storage will be allocated by subsequent calls to `operator new` or any of `aligned_alloc`, `calloc`, `malloc`, or `realloc`, declared in `<cstdlib>`.
- ```
void operator delete(void* ptr, const std::nothrow_t&) noexcept;
void operator delete(void* ptr, std::align_val_t alignment, const std::nothrow_t&) noexcept;
```
- 19     *Effects:* The deallocation functions (??) called by the implementation to render the value of `ptr` invalid when the constructor invoked from a `nothrow` placement version of the *new-expression* throws an exception.
- 20     *Replaceable:* A C++ program may define functions with either of these function signatures, and thereby displace the default versions defined by the C++ standard library.
- 21     *Requires:* `ptr` shall be a null pointer or its value shall represent the address of a block of memory allocated by an earlier call to a (possibly replaced) `operator new(std::size_t)` or `operator new(std::size_t, std::align_val_t)` which has not been invalidated by an intervening call to `operator delete`.
- 22     *Requires:* If an implementation has strict pointer safety (??) then `ptr` shall be a safely-derived pointer.
- 23     *Requires:* If the `alignment` parameter is not present, `ptr` shall have been returned by an allocation function without an `alignment` parameter. If present, the `alignment` argument shall equal the `alignment` argument passed to the allocation function that returned `ptr`.
- 24     *Default behavior:* Calls `operator delete(ptr)`, or `operator delete(ptr, alignment)`, respectively.

### 21.6.2.2 Array forms

[`new.delete.array`]

```
[[nodiscard]] void* operator new[](std::size_t size);
[[nodiscard]] void* operator new[](std::size_t size, std::align_val_t alignment);
```

- 1     *Effects:* The allocation functions (??) called by the array form of a *new-expression* (??) to allocate `size` bytes of storage. The second form is called for a type with new-extended alignment, and allocates storage with the specified alignment. The first form is called otherwise, and allocates storage suitably aligned to represent any array object of that size or smaller, provided the object's type does not have new-extended alignment.<sup>222</sup>
- 2     *Replaceable:* A C++ program may define functions with either of these function signatures, and thereby displace the default versions defined by the C++ standard library.
- 3     *Required behavior:* Same as for the corresponding single-object forms. This requirement is binding on any replacement versions of these functions.
- 4     *Default behavior:* Returns `operator new(size)`, or `operator new(size, alignment)`, respectively.

```
[[nodiscard]] void* operator new[](std::size_t size, const std::nothrow_t&) noexcept;
```

<sup>222</sup>) It is not the direct responsibility of `operator new[]` or `operator delete[]` to note the repetition count or element size of the array. Those operations are performed elsewhere in the array `new` and `delete` expressions. The array `new` expression, however, increase the `size` argument to `operator new[]` to obtain space to store supplemental information.

```
[[nodiscard]] void* operator new[](std::size_t size, std::align_val_t alignment,
                                const std::nothrow_t&) noexcept;
```

5     *Effects:* Same as above, except that these are called by a placement version of a *new-expression* when a C++ program prefers a null pointer result as an error indication, instead of a `bad_alloc` exception.

6     *Replaceable:* A C++ program may define functions with either of these function signatures, and thereby displace the default versions defined by the C++ standard library.

7     *Required behavior:* Return a non-null pointer to suitably aligned storage (??), or else return a null pointer. Each of these `nothrow` versions of `operator new[]` returns a pointer obtained as if acquired from the (possibly replaced) corresponding non-placement function. This requirement is binding on any replacement versions of these functions.

8     *Default behavior:* Calls `operator new[](size)`, or `operator new[](size, alignment)`, respectively. If the call returns normally, returns the result of that call. Otherwise, returns a null pointer.

```
void operator delete[](void* ptr) noexcept;
void operator delete[](void* ptr, std::size_t size) noexcept;
void operator delete[](void* ptr, std::align_val_t alignment) noexcept;
void operator delete[](void* ptr, std::size_t size, std::align_val_t alignment) noexcept;
```

9     *Effects:* The deallocation functions (??) called by the array form of a *delete-expression* to render the value of `ptr` invalid.

10    *Replaceable:* A C++ program may define functions with any of these function signatures, and thereby displace the default versions defined by the C++ standard library. If a function without a `size` parameter is defined, the program should also define the corresponding function with a `size` parameter. If a function with a `size` parameter is defined, the program shall also define the corresponding version without the `size` parameter. [ *Note:* The default behavior below may change in the future, which will require replacing both deallocation functions when replacing the allocation function. — *end note* ]

11    *Requires:* `ptr` shall be a null pointer or its value shall represent the address of a block of memory allocated by an earlier call to a (possibly replaced) `operator new[](std::size_t)` or `operator new[](std::size_t, std::align_val_t)` which has not been invalidated by an intervening call to `operator delete[]`.

12    *Requires:* If an implementation has strict pointer safety (??) then `ptr` shall be a safely-derived pointer.

13    *Requires:* If the `alignment` parameter is not present, `ptr` shall have been returned by an allocation function without an `alignment` parameter. If present, the `alignment` argument shall equal the `alignment` argument passed to the allocation function that returned `ptr`. If present, the `size` argument shall equal the `size` argument passed to the allocation function that returned `ptr`.

14    *Required behavior:* A call to an `operator delete[]` with a `size` parameter may be changed to a call to the corresponding `operator delete[]` without a `size` parameter, without affecting memory allocation. [ *Note:* A conforming implementation is for `operator delete[](void* ptr, std::size_t size)` to simply call `operator delete[](ptr)`. — *end note* ]

15    *Default behavior:* The functions that have a `size` parameter forward their other parameters to the corresponding function without a `size` parameter. The functions that do not have a `size` parameter forward their parameters to the corresponding `operator delete` (single-object) function.

```
void operator delete[](void* ptr, const std::nothrow_t&) noexcept;
```

```
void operator delete[](void* ptr, std::align_val_t alignment, const std::nothrow_t&) noexcept;
```

16     *Effects:* The deallocation functions (??) called by the implementation to render the value of `ptr` invalid when the constructor invoked from a `nothrow` placement version of the array *new-expression* throws an exception.

17     *Replaceable:* A C++ program may define functions with either of these function signatures, and thereby displace the default versions defined by the C++ standard library.

18     *Requires:* `ptr` shall be a null pointer or its value shall represent the address of a block of memory allocated by an earlier call to a (possibly replaced) `operator new[](std::size_t)` or `operator new[](std::size_t, std::align_val_t)` which has not been invalidated by an intervening call to `operator delete[]`.

19     *Requires:* If an implementation has strict pointer safety (??) then `ptr` shall be a safely-derived pointer.

20     *Requires:* If the `alignment` parameter is not present, `ptr` shall have been returned by an allocation function without an `alignment` parameter. If present, the `alignment` argument shall equal the `alignment` argument passed to the allocation function that returned `ptr`.

21     *Default behavior:* Calls `operator delete[](ptr)`, or `operator delete[](ptr, alignment)`, respectively.

### 21.6.2.3 Non-allocating forms

**[new.delete.placement]**

1 These functions are reserved; a C++ program may not define functions that displace the versions in the C++ standard library (??). The provisions of ?? do not apply to these reserved placement forms of `operator new` and `operator delete`.

```
[[nodiscard]] void* operator new(std::size_t size, void* ptr) noexcept;
```

2     *Returns:* `ptr`.

3     *Remarks:* Intentionally performs no other action.

4     *[Example:* This can be useful for constructing an object at a known address:

```
void* place = operator new(sizeof(Something));
Something* p = new (place) Something();
```

— *end example*]

```
[[nodiscard]] void* operator new[](std::size_t size, void* ptr) noexcept;
```

5     *Returns:* `ptr`.

6     *Remarks:* Intentionally performs no other action.

```
void operator delete(void* ptr, void*) noexcept;
```

7     *Effects:* Intentionally performs no action.

8     *Requires:* If an implementation has strict pointer safety (??) then `ptr` shall be a safely-derived pointer.

9     *Remarks:* Default function called when any part of the initialization in a placement *new-expression* that invokes the library's non-array placement operator `new` terminates by throwing an exception (??).

```
void operator delete[](void* ptr, void*) noexcept;
```

10     *Effects:* Intentionally performs no action.

11     *Requires:* If an implementation has strict pointer safety (??) then `ptr` shall be a safely-derived pointer.

- <sup>12</sup> *Remarks:* Default function called when any part of the initialization in a placement *new-expression* that invokes the library's array placement operator new terminates by throwing an exception (??).

#### 21.6.2.4 Data races

[**new.delete.dataraces**]

- <sup>1</sup> For purposes of determining the existence of data races, the library versions of `operator new`, user replacement versions of global `operator new`, the C standard library functions `aligned_alloc`, `calloc`, and `malloc`, the library versions of `operator delete`, user replacement versions of `operator delete`, the C standard library function `free`, and the C standard library function `realloc` shall not introduce a data race (??). Calls to these functions that allocate or deallocate a particular unit of storage shall occur in a single total order, and each such deallocation call shall happen before (??) the next allocation (if any) in this order.

#### 21.6.3 Storage allocation errors

[**alloc.errors**]

##### 21.6.3.1 Class `bad_alloc`

[**bad.alloc**]

```
namespace std {
    class bad_alloc : public exception {
        public:
            bad_alloc() noexcept;
            bad_alloc(const bad_alloc&) noexcept;
            bad_alloc& operator=(const bad_alloc&) noexcept;
            const char* what() const noexcept override;
    };
}
```

- <sup>1</sup> The class `bad_alloc` defines the type of objects thrown as exceptions by the implementation to report a failure to allocate storage.

`bad_alloc() noexcept;`

- <sup>2</sup> *Effects:* Constructs an object of class `bad_alloc`.

```
bad_alloc(const bad_alloc&) noexcept;
bad_alloc& operator=(const bad_alloc&) noexcept;
```

- <sup>3</sup> *Effects:* Copies an object of class `bad_alloc`.

`const char* what() const noexcept override;`

- <sup>4</sup> *Returns:* An implementation-defined NTBS.

- <sup>5</sup> *Remarks:* The message may be a null-terminated multibyte string (??), suitable for conversion and display as a `wstring` (??, ??).

##### 21.6.3.2 Class `bad_array_new_length`

[**new.badlength**]

```
namespace std {
    class bad_array_new_length : public bad_alloc {
        public:
            bad_array_new_length() noexcept;
            const char* what() const noexcept override;
    };
}
```

- <sup>1</sup> The class `bad_array_new_length` defines the type of objects thrown as exceptions by the implementation to report an attempt to allocate an array of size less than zero or greater than an implementation-defined limit (??).

```
bad_array_new_length() noexcept;
```

- <sup>2</sup> *Effects:* Constructs an object of class `bad_array_new_length`.

```
const char* what() const noexcept override;
```

- <sup>3</sup> *Returns:* An implementation-defined NTBS.

- <sup>4</sup> *Remarks:* The message may be a null-terminated multibyte string (??), suitable for conversion and display as a `wstring` (??, ??).

### 21.6.3.3 Type `new_handler`

[`new.handler`]

```
using new_handler = void (*)();
```

- <sup>1</sup> The type of a *handler function* to be called by `operator new()` or `operator new[]()` (??) when they cannot satisfy a request for additional storage.

- <sup>2</sup> *Required behavior:* A `new_handler` shall perform one of the following:

- (2.1) — make more storage available for allocation and then return;
- (2.2) — throw an exception of type `bad_alloc` or a class derived from `bad_alloc`;
- (2.3) — terminate execution of the program without returning to the caller.

### 21.6.3.4 `set_new_handler`

[`set.new.handler`]

```
new_handler set_new_handler(new_handler new_p) noexcept;
```

- <sup>1</sup> *Effects:* Establishes the function designated by `new_p` as the current `new_handler`.

- <sup>2</sup> *Returns:* The previous `new_handler`.

- <sup>3</sup> *Remarks:* The initial `new_handler` is a null pointer.

### 21.6.3.5 `get_new_handler`

[`get.new.handler`]

```
new_handler get_new_handler() noexcept;
```

- <sup>1</sup> *Returns:* The current `new_handler`. [ *Note:* This may be a null pointer value. — *end note* ]

### 21.6.4 Pointer optimization barrier

[`ptr.launder`]

```
template<class T> [[nodiscard]] constexpr T* launder(T* p) noexcept;
```

- <sup>1</sup> *Requires:* `p` represents the address `A` of a byte in memory. An object `X` that is within its lifetime (??) and whose type is similar (??) to `T` is located at the address `A`. All bytes of storage that would be reachable through the result are reachable through `p` (see below).

- <sup>2</sup> *Returns:* A value of type `T *` that points to `X`.

- <sup>3</sup> *Remarks:* An invocation of this function may be used in a core constant expression whenever the value of its argument may be used in a core constant expression. A byte of storage is reachable through a pointer value that points to an object `Y` if it is within the storage occupied by `Y`, an object that is pointer-interconvertible with `Y`, or the immediately-enclosing array object if `Y` is an array element. The program is ill-formed if `T` is a function type or *cv void*.

<sup>4</sup> [Note: If a new object is created in storage occupied by an existing object of the same type, a pointer to the original object can be used to refer to the new object unless the type contains `const` or reference members; in the latter cases, this function can be used to obtain a usable pointer to the new object. See [??](#). —end note]

<sup>5</sup> [Example:

```
struct X { const int n; };
X *p = new X{3};
const int a = p->n;
new (p) X{5};                                // p does not point to new object (??) because X::n is const
const int b = p->n;                          // undefined behavior
const int c = std::launder(p)->n;           // OK
— end example]
```

## 21.6.5 Hardware interference size

[hardware.interference]

`inline constexpr size_t hardware_destructive_interference_size = implementation-defined;`

<sup>1</sup> This number is the minimum recommended offset between two concurrently-accessed objects to avoid additional performance degradation due to contention introduced by the implementation. It shall be at least `alignof(max_align_t)`.

[Example:

```
struct keep_apart {
    alignas(hardware_destructive_interference_size) atomic<int> cat;
    alignas(hardware_destructive_interference_size) atomic<int> dog;
};
```

— end example]

`inline constexpr size_t hardware_constructive_interference_size = implementation-defined;`

<sup>2</sup> This number is the maximum recommended size of contiguous memory occupied by two objects accessed with temporal locality by concurrent threads. It shall be at least `alignof(max_align_t)`.

[Example:

```
struct together {
    atomic<int> dog;
    int puppy;
};

struct kennel {
    // Other data members...
    alignas(sizeof(together)) together pack;
    // Other data members...
};

static_assert(sizeof(together) <= hardware_constructive_interference_size);
— end example]
```

## 21.7 Type identification

[support.rtti]

<sup>1</sup> The header `<typeinfo>` defines a type associated with type information generated by the implementation. It also defines two types for reporting dynamic type identification errors.

### 21.7.1 Header <typeinfo> synopsis

[typeinfo.syn]

```
namespace std {
    class type_info;
    class bad_cast;
    class bad_typeid;
}
```

### 21.7.2 Class type\_info

[type.info]

```
namespace std {
    class type_info {
        public:
            virtual ~type_info();
            bool operator==(const type_info& rhs) const noexcept;
            bool operator!=(const type_info& rhs) const noexcept;
            bool before(const type_info& rhs) const noexcept;
            size_t hash_code() const noexcept;
            const char* name() const noexcept;

            type_info(const type_info& rhs) = delete; // cannot be copied
            type_info& operator=(const type_info& rhs) = delete; // cannot be copied
    };
}
```

- <sup>1</sup> The class `type_info` describes type information generated by the implementation (??). Objects of this class effectively store a pointer to a name for the type, and an encoded value suitable for comparing two types for equality or collating order. The names, encoding rule, and collating sequence for types are all unspecified and may differ between programs.

`bool operator==(const type_info& rhs) const noexcept;`

- <sup>2</sup> *Effects:* Compares the current object with `rhs`.

- <sup>3</sup> *Returns:* `true` if the two values describe the same type.

`bool operator!=(const type_info& rhs) const noexcept;`

- <sup>4</sup> *Returns:* `!(*this == rhs)`.

`bool before(const type_info& rhs) const noexcept;`

- <sup>5</sup> *Effects:* Compares the current object with `rhs`.

- <sup>6</sup> *Returns:* `true` if `*this` precedes `rhs` in the implementation's collation order.

`size_t hash_code() const noexcept;`

- <sup>7</sup> *Returns:* An unspecified value, except that within a single execution of the program, it shall return the same value for any two `type_info` objects which compare equal.

- <sup>8</sup> *Remarks:* An implementation should return different values for two `type_info` objects which do not compare equal.

`const char* name() const noexcept;`

- <sup>9</sup> *Returns:* An implementation-defined NTBS.

- 10        *Remarks:* The message may be a null-terminated multibyte string (??), suitable for conversion and display as a `wstring` (??, ??)

### 21.7.3 Class `bad_cast`

[`bad.cast`]

```
namespace std {
    class bad_cast : public exception {
        public:
            bad_cast() noexcept;
            bad_cast(const bad_cast&) noexcept;
            bad_cast& operator=(const bad_cast&) noexcept;
            const char* what() const noexcept override;
    };
}
```

- 1        The class `bad_cast` defines the type of objects thrown as exceptions by the implementation to report the execution of an invalid `dynamic_cast` expression (??).

`bad_cast() noexcept;`

- 2        *Effects:* Constructs an object of class `bad_cast`.

```
bad_cast(const bad_cast&) noexcept;
bad_cast& operator=(const bad_cast&) noexcept;
```

- 3        *Effects:* Copies an object of class `bad_cast`.

`const char* what() const noexcept override;`

- 4        *Returns:* An implementation-defined NTBS.

- 5        *Remarks:* The message may be a null-terminated multibyte string (??), suitable for conversion and display as a `wstring` (??, ??)

### 21.7.4 Class `bad_typeid`

[`bad.typeid`]

```
namespace std {
    class bad_typeid : public exception {
        public:
            bad_typeid() noexcept;
            bad_typeid(const bad_typeid&) noexcept;
            bad_typeid& operator=(const bad_typeid&) noexcept;
            const char* what() const noexcept override;
    };
}
```

- 1        The class `bad_typeid` defines the type of objects thrown as exceptions by the implementation to report a null pointer in a `typeid` expression (??).

`bad_typeid() noexcept;`

- 2        *Effects:* Constructs an object of class `bad_typeid`.

```
bad_typeid(const bad_typeid&) noexcept;
bad_typeid& operator=(const bad_typeid&) noexcept;
```

- 3        *Effects:* Copies an object of class `bad_typeid`.

```
const char* what() const noexcept override;
```

<sup>4</sup> *Returns:* An implementation-defined NTBS.

<sup>5</sup> *Remarks:* The message may be a null-terminated multibyte string (??), suitable for conversion and display as a `wstring` (??, ??)

## 21.8 Exception handling

[support.exception]

<sup>1</sup> The header `<exception>` defines several types and functions related to the handling of exceptions in a C++ program.

### 21.8.1 Header `<exception>` synopsis

[exception.syn]

```
namespace std {
    class exception;
    class bad_exception;
    class nested_exception;

    using terminate_handler = void (*)();
    terminate_handler get_terminate() noexcept;
    terminate_handler set_terminate(terminate_handler f) noexcept;
    [[noreturn]] void terminate() noexcept;

    int uncaught_exceptions() noexcept;

    using exception_ptr = unspecified;

    exception_ptr current_exception() noexcept;
    [[noreturn]] void rethrow_exception(exception_ptr p);
    template<class E> exception_ptr make_exception_ptr(E e) noexcept;

    template<class T> [[noreturn]] void throw_with_nested(T&& t);
    template<class E> void rethrow_if_nested(const E& e);
}
```

### 21.8.2 Class `exception`

[exception]

```
namespace std {
    class exception {
        public:
            exception() noexcept;
            exception(const exception&) noexcept;
            exception& operator=(const exception&) noexcept;
            virtual ~exception();
            virtual const char* what() const noexcept;
    };
}
```

<sup>1</sup> The class `exception` defines the base class for the types of objects thrown as exceptions by C++ standard library components, and certain expressions, to report errors detected during program execution.

<sup>2</sup> Each standard library class `T` that derives from class `exception` shall have a publicly accessible copy constructor and a publicly accessible copy assignment operator that do not exit with an exception. These

member functions shall meet the following postcondition: If two objects `lhs` and `rhs` both have dynamic type `T` and `lhs` is a copy of `rhs`, then `strcmp(lhs.what(), rhs.what())` shall equal 0.

```
exception() noexcept;
```

3     *Effects:* Constructs an object of class `exception`.

```
exception(const exception& rhs) noexcept;
exception& operator=(const exception& rhs) noexcept;
```

4     *Effects:* Copies an `exception` object.

5     *Postconditions:* If `*this` and `rhs` both have dynamic type `exception` then the value of the expression `strcmp(what(), rhs.what())` shall equal 0.

```
virtual ~exception();
```

6     *Effects:* Destroys an object of class `exception`.

```
virtual const char* what() const noexcept;
```

7     *Returns:* An implementation-defined NTBS.

8     *Remarks:* The message may be a null-terminated multibyte string (??), suitable for conversion and display as a `wstring` (??, ??). The return value remains valid until the exception object from which it is obtained is destroyed or a non-`const` member function of the exception object is called.

### 21.8.3 Class `bad_exception`

[`bad.exception`]

```
namespace std {
    class bad_exception : public exception {
        public:
            bad_exception() noexcept;
            bad_exception(const bad_exception&) noexcept;
            bad_exception& operator=(const bad_exception&) noexcept;
            const char* what() const noexcept override;
    };
}
```

1     The class `bad_exception` defines the type of the object referenced by the `exception_ptr` returned from a call to `current_exception` (??) when the currently active exception object fails to copy.

```
bad_exception() noexcept;
```

2     *Effects:* Constructs an object of class `bad_exception`.

```
bad_exception(const bad_exception&) noexcept;
bad_exception& operator=(const bad_exception&) noexcept;
```

3     *Effects:* Copies an object of class `bad_exception`.

```
const char* what() const noexcept override;
```

4     *Returns:* An implementation-defined NTBS.

5     *Remarks:* The message may be a null-terminated multibyte string (??), suitable for conversion and display as a `wstring` (??, ??).

**21.8.4 Abnormal termination** [exception.terminate]**21.8.4.1 Type terminate\_handler** [terminate.handler]

```
using terminate_handler = void (*)();
```

- 1 The type of a *handler function* to be called by `std::terminate()` when terminating exception processing.
- 2 *Required behavior:* A `terminate_handler` shall terminate execution of the program without returning to the caller.
- 3 *Default behavior:* The implementation's default `terminate_handler` calls `abort()`.

**21.8.4.2 set\_terminate** [set.terminate]

```
terminate_handler set_terminate(terminate_handler f) noexcept;
```

- 1 *Effects:* Establishes the function designated by `f` as the current handler function for terminating exception processing.
- 2 *Remarks:* It is unspecified whether a null pointer value designates the default `terminate_handler`.
- 3 *Returns:* The previous `terminate_handler`.

**21.8.4.3 get\_terminate** [get.terminate]

```
terminate_handler get_terminate() noexcept;
```

- 1 *Returns:* The current `terminate_handler`. [Note: This may be a null pointer value. —end note]

**21.8.4.4 terminate** [terminate]

```
[[noreturn]] void terminate() noexcept;
```

- 1 *Remarks:* Called by the implementation when exception handling must be abandoned for any of several reasons (??). May also be called directly by the program.
- 2 *Effects:* Calls a `terminate_handler` function. It is unspecified which `terminate_handler` function will be called if an exception is active during a call to `set_terminate`. Otherwise calls the current `terminate_handler` function. [Note: A default `terminate_handler` is always considered a callable handler in this context. —end note]

**21.8.5 uncaught\_exceptions** [uncaught.exceptions]

```
int uncaught_exceptions() noexcept;
```

- 1 *Returns:* The number of uncaught exceptions (??).
- 2 *Remarks:* When `uncaught_exceptions() > 0`, throwing an exception can result in a call of `std::terminate()` (??).

**21.8.6 Exception propagation** [propagation]

```
using exception_ptr = unspecified;
```

- 1 The type `exception_ptr` can be used to refer to an exception object.
- 2 `exception_ptr` shall satisfy the requirements of `NullablePointer` (??).
- 3 Two non-null values of type `exception_ptr` are equivalent and compare equal if and only if they refer to the same exception.

- 4     The default constructor of `exception_ptr` produces the null value of the type.
- 5     `exception_ptr` shall not be implicitly convertible to any arithmetic, enumeration, or pointer type.
- 6     [ *Note:* An implementation might use a reference-counted smart pointer as `exception_ptr`. — *end note* ]
- 7     For purposes of determining the presence of a data race, operations on `exception_ptr` objects shall access and modify only the `exception_ptr` objects themselves and not the exceptions they refer to. Use of `rethrow_exception` on `exception_ptr` objects that refer to the same exception object shall not introduce a data race. [ *Note:* If `rethrow_exception` rethrows the same exception object (rather than a copy), concurrent access to that rethrown exception object may introduce a data race. Changes in the number of `exception_ptr` objects that refer to a particular exception do not introduce a data race. — *end note* ]

```
exception_ptr current_exception() noexcept;
```

- 8     *Returns:* An `exception_ptr` object that refers to the currently handled exception (??) or a copy of the currently handled exception, or a null `exception_ptr` object if no exception is being handled. The referenced object shall remain valid at least as long as there is an `exception_ptr` object that refers to it. If the function needs to allocate memory and the attempt fails, it returns an `exception_ptr` object that refers to an instance of `bad_alloc`. It is unspecified whether the return values of two successive calls to `current_exception` refer to the same exception object. [ *Note:* That is, it is unspecified whether `current_exception` creates a new copy each time it is called. — *end note* ] If the attempt to copy the current exception object throws an exception, the function returns an `exception_ptr` object that refers to the thrown exception or, if this is not possible, to an instance of `bad_exception`. [ *Note:* The copy constructor of the thrown exception may also fail, so the implementation is allowed to substitute a `bad_exception` object to avoid infinite recursion. — *end note* ]

```
[[noreturn]] void rethrow_exception(exception_ptr p);
```

- 9     *Requires:* `p` shall not be a null pointer.

- 10    *Throws:* The exception object to which `p` refers.

```
template<class E> exception_ptr make_exception_ptr(E e) noexcept;
```

- 11    *Effects:* Creates an `exception_ptr` object that refers to a copy of `e`, as if:

```
try {
    throw e;
} catch(...) {
    return current_exception();
}
```

- 12    [ *Note:* This function is provided for convenience and efficiency reasons. — *end note* ]

### 21.8.7 nested\_exception

[`except.nested`]

```
namespace std {
    class nested_exception {
        public:
            nested_exception() noexcept;
            nested_exception(const nested_exception&) noexcept = default;
            nested_exception& operator=(const nested_exception&) noexcept = default;
            virtual ~nested_exception() = default;
```

```
// access functions
[[noreturn]] void rethrow_nested() const;
exception_ptr nested_ptr() const noexcept;
};

template<class T> [[noreturn]] void throw_with_nested(T&& t);
template<class E> void rethrow_if_nested(const E& e);
}
```

- <sup>1</sup> The class `nested_exception` is designed for use as a mixin through multiple inheritance. It captures the currently handled exception and stores it for later use.
- <sup>2</sup> [ *Note:* `nested_exception` has a virtual destructor to make it a polymorphic class. Its presence can be tested for with `dynamic_cast`. — *end note* ]

`nested_exception() noexcept;`

- <sup>3</sup> *Effects:* The constructor calls `current_exception()` and stores the returned value.

`[[noreturn]] void rethrow_nested() const;`

- <sup>4</sup> *Effects:* If `nested_ptr()` returns a null pointer, the function calls `std::terminate()`. Otherwise, it throws the stored exception captured by `*this`.

`exception_ptr nested_ptr() const noexcept;`

- <sup>5</sup> *Returns:* The stored exception captured by this `nested_exception` object.

`template<class T> [[noreturn]] void throw_with_nested(T&& t);`

- <sup>6</sup> Let U be `decay_t<T>`.

- <sup>7</sup> *Requires:* U shall be `CopyConstructible`.

- <sup>8</sup> *Throws:* If `is_class_v<U> && !is_final_v<U> && !is_base_of_v<nested_exception, U>` is true, an exception of unspecified type that is publicly derived from both U and `nested_exception` and constructed from `std::forward<T>(t)`, otherwise `std::forward<T>(t)`.

`template<class E> void rethrow_if_nested(const E& e);`

- <sup>9</sup> *Effects:* If E is not a polymorphic class type, or if `nested_exception` is an inaccessible or ambiguous base class of E, there is no effect. Otherwise, performs:

```
if (auto p = dynamic_cast<const nested_exception*>(addressof(e)))
    p->rethrow_nested();
```

## 21.9 Initializer lists

[support.initlist]

- <sup>1</sup> The header `<initializer_list>` defines a class template and several support functions related to list-initialization (see ??). All functions specified in this subclause are signal-safe (??).

### 21.9.1 Header `<initializer_list>` synopsis

[initializer\_list.syn]

```
namespace std {
    template<class E> class initializer_list {
        public:
            using value_type      = E;
            using reference       = const E&;
            using const_reference = const E&;
```

```

    using size_type      = size_t;

    using iterator       = const E*;
    using const_iterator = const E*;

    constexpr initializer_list() noexcept;

    constexpr size_t size() const noexcept;      // number of elements
    constexpr const E* begin() const noexcept;    // first element
    constexpr const E* end() const noexcept;       // one past the last element
};

// ??, initializer list range access
template<class E> constexpr const E* begin(initializer_list<E> il) noexcept;
template<class E> constexpr const E* end(initializer_list<E> il) noexcept;
}

```

- <sup>1</sup> An object of type `initializer_list<E>` provides access to an array of objects of type `const E`. [Note: A pair of pointers or a pointer plus a length would be obvious representations for `initializer_list`. `initializer_list` is used to implement initializer lists as specified in ???. Copying an initializer list does not copy the underlying elements. —end note]
- <sup>2</sup> If an explicit specialization or partial specialization of `initializer_list` is declared, the program is ill-formed.

### 21.9.2 Initializer list constructors

[support.initlist.cons]

```
constexpr initializer_list() noexcept;
```

- <sup>1</sup> *Effects:* Constructs an empty `initializer_list` object.
- <sup>2</sup> *Postconditions:* `size() == 0`.

### 21.9.3 Initializer list access

[support.initlist.access]

```
constexpr const E* begin() const noexcept;
```

- <sup>1</sup> *Returns:* A pointer to the beginning of the array. If `size() == 0` the values of `begin()` and `end()` are unspecified but they shall be identical.

```
constexpr const E* end() const noexcept;
```

- <sup>2</sup> *Returns:* `begin() + size()`.

```
constexpr size_t size() const noexcept;
```

- <sup>3</sup> *Returns:* The number of elements in the array.

- <sup>4</sup> *Complexity:* Constant time.

### 21.9.4 Initializer list range access

[support.initlist.range]

```
template<class E> constexpr const E* begin(initializer_list<E> il) noexcept;
```

- <sup>1</sup> *Returns:* `il.begin()`.

template<class E> constexpr const E\* end(initializer\_list<E> il) noexcept;  
 2       >Returns: il.end().

## 21.10 Comparisons

[cmp]

### 21.10.1 Header <compare> synopsis

[cmp.syn]

- <sup>1</sup> The header <compare> specifies types, objects, and functions for use primarily in connection with the three-way comparison operator (??).

```
namespace std {
    // ??, comparison category types
    class weak_equality;
    class strong_equality;
    class partial_ordering;
    class weak_ordering;
    class strong_ordering;

    // named comparison functions
    constexpr bool is_eq (weak_equality cmp) noexcept { return cmp == 0; }
    constexpr bool is_neq (weak_equality cmp) noexcept { return cmp != 0; }
    constexpr bool is_lt (partial_ordering cmp) noexcept { return cmp < 0; }
    constexpr bool is_lteq(partial_ordering cmp) noexcept { return cmp <= 0; }
    constexpr bool is_gt (partial_ordering cmp) noexcept { return cmp > 0; }
    constexpr bool is_gteq(partial_ordering cmp) noexcept { return cmp >= 0; }

    // ??, common comparison category type
    template<class... Ts>
    struct common_comparison_category {
        using type = see below;
    };
    template<class... Ts>
    using common_comparison_category_t = typename common_comparison_category<Ts...>::type;

    // ??, comparison algorithms
    template<class T> constexpr strong_ordering strong_order(const T& a, const T& b);
    template<class T> constexpr weak_ordering weak_order(const T& a, const T& b);
    template<class T> constexpr partial_ordering partial_order(const T& a, const T& b);
    template<class T> constexpr strong_equality strong_equal(const T& a, const T& b);
    template<class T> constexpr weak_equality weak_equal(const T& a, const T& b);
}
```

### 21.10.2 Comparison category types

[cmp.categories]

#### 21.10.2.1 Preamble

[cmp.categories.pre]

- <sup>1</sup> The types `weak_equality`, `strong_equality`, `partial_ordering`, `weak_ordering`, and `strong_ordering` are collectively termed the *comparison category types*. Each is specified in terms of an exposition-only data member named `value` whose value typically corresponds to that of an enumerator from one of the following exposition-only enumerations:

```
enum class eq { equal = 0, equivalent = equal,
               nonequal = 1, nonequivalent = nonequal }; // exposition only
```

```
enum class ord { less = -1, greater = 1 };           // exposition only
enum class ncmp { unordered = -127 };               // exposition only
```

- <sup>2</sup> [ *Note:* The types `strong_ordering` and `weak_equality` correspond, respectively, to the terms total ordering and equivalence in mathematics. — *end note* ]
- <sup>3</sup> The relational and equality operators for the comparison category types are specified with an anonymous parameter of unspecified type. This type shall be selected by the implementation such that these parameters can accept literal 0 as a corresponding argument. [ *Example:* `nullptr_t` satisfies this requirement. — *end example* ] In this context, the behavior of a program that supplies an argument other than a literal 0 is undefined.
- <sup>4</sup> For the purposes of this subclause, *substitutability* is the property that `f(a) == f(b)` is `true` whenever `a == b` is true, where `f` denotes a function that reads only comparison-salient state that is accessible via the argument's public `const` members.

### 21.10.2.2 Class `weak_equality`

[`cmp.weakeq`]

- <sup>1</sup> The `weak_equality` type is typically used as the result type of a three-way comparison operator (??) that (a) admits only equality and inequality comparisons, and (b) does not imply substitutability.

```
namespace std {
    class weak_equality {
        int value; // exposition only

        // exposition-only constructor
        explicit constexpr weak_equality(eq v) noexcept : value(int(v)) {} // exposition only

    public:
        // valid values
        static const weak_equality equivalent;
        static const weak_equality nonequivalent;

        // comparisons
        friend constexpr bool operator==(weak_equality v, unspecified) noexcept;
        friend constexpr bool operator!=(weak_equality v, unspecified) noexcept;
        friend constexpr bool operator==(unspecified, weak_equality v) noexcept;
        friend constexpr bool operator!=(unspecified, weak_equality v) noexcept;
    };

    // valid values' definitions
    inline constexpr weak_equality weak_equality::equivalent(eq::equivalent);
    inline constexpr weak_equality weak_equality::nonequivalent(eq::nonequivalent);
}

constexpr bool operator==(weak_equality v, unspecified) noexcept;
constexpr bool operator==(unspecified, weak_equality v) noexcept;

2     Returns: v.value == 0.

constexpr bool operator!=(weak_equality v, unspecified) noexcept;
constexpr bool operator!=(unspecified, weak_equality v) noexcept;

3     Returns: v.value != 0.
```

**21.10.2.3 Class strong\_equality**

[cmp.strongeq]

- <sup>1</sup> The `strong_equality` type is typically used as the result type of a three-way comparison operator (??) that (a) admits only equality and inequality comparisons, and (b) does imply substitutability.

```

namespace std {
    class strong_equality {
        int value; // exposition only

        // exposition-only constructor
        explicit constexpr strong_equality(eq v) noexcept : value(int(v)) {} // exposition only

    public:
        // valid values
        static const strong_equality equal;
        static const strong_equality nonequal;
        static const strong_equality equivalent;
        static const strong_equality nonequivalent;

        // conversion
        constexpr operator weak_equality() const noexcept;

        // comparisons
        friend constexpr bool operator==(strong_equality v, unspecified) noexcept;
        friend constexpr bool operator!=(strong_equality v, unspecified) noexcept;
        friend constexpr bool operator==(unspecified, strong_equality v) noexcept;
        friend constexpr bool operator!=(unspecified, strong_equality v) noexcept;
    };

    // valid values' definitions
    inline constexpr strong_equality strong_equality::equal(eq::equal);
    inline constexpr strong_equality strong_equality::nonequal(eq::nonequal);
    inline constexpr strong_equality strong_equality::equivalent(eq::equivalent);
    inline constexpr strong_equality strong_equality::nonequivalent(eq::nonequivalent);
}

constexpr operator weak_equality() const noexcept;

2 Returns: value == 0 ? weak_equality::equivalent : weak_equality::nonequivalent.
constexpr bool operator==(strong_equality v, unspecified) noexcept;
constexpr bool operator==(unspecified, strong_equality v) noexcept;

3 Returns: v.value == 0.
constexpr bool operator!=(strong_equality v, unspecified) noexcept;
constexpr bool operator!=(unspecified, strong_equality v) noexcept;

4 Returns: v.value != 0.
```

**21.10.2.4 Class partial\_ordering**

[cmp.partialord]

- <sup>1</sup> The `partial_ordering` type is typically used as the result type of a three-way comparison operator (??) that (a) admits all of the six two-way comparison operators (??, ??), (b) does not imply substitutability, and

(c) permits two values to be incomparable.<sup>223</sup>

```

namespace std {
    class partial_ordering {
        int value;           // exposition only
        bool is_ordered;    // exposition only

        // exposition-only constructors
        explicit constexpr
            partial_ordering(eq v) noexcept : value(int(v)), is_ordered(true) {}      // exposition only
        explicit constexpr
            partial_ordering(ord v) noexcept : value(int(v)), is_ordered(true) {}      // exposition only
        explicit constexpr
            partial_ordering(ncmp v) noexcept : value(int(v)), is_ordered(false) {}   // exposition only

    public:
        // valid values
        static const partial_ordering less;
        static const partial_ordering equivalent;
        static const partial_ordering greater;
        static const partial_ordering unordered;

        // conversion
        constexpr operator weak_equality() const noexcept;

        // comparisons
        friend constexpr bool operator==(partial_ordering v, unspecified) noexcept;
        friend constexpr bool operator!=(partial_ordering v, unspecified) noexcept;
        friend constexpr bool operator< (partial_ordering v, unspecified) noexcept;
        friend constexpr bool operator<=(partial_ordering v, unspecified) noexcept;
        friend constexpr bool operator> (partial_ordering v, unspecified) noexcept;
        friend constexpr bool operator>=(partial_ordering v, unspecified) noexcept;
        friend constexpr bool operator==(unspecified, partial_ordering v) noexcept;
        friend constexpr bool operator!=(unspecified, partial_ordering v) noexcept;
        friend constexpr bool operator< (unspecified, partial_ordering v) noexcept;
        friend constexpr bool operator<=(unspecified, partial_ordering v) noexcept;
        friend constexpr bool operator> (unspecified, partial_ordering v) noexcept;
        friend constexpr bool operator>=(unspecified, partial_ordering v) noexcept;
    };

    // valid values' definitions
    inline constexpr partial_ordering partial_ordering::less(ord::less);
    inline constexpr partial_ordering partial_ordering::equivalent(eq::equivalent);
    inline constexpr partial_ordering partial_ordering::greater(ord::greater);
    inline constexpr partial_ordering partial_ordering::unordered(ncmp::unordered);
}

```

---

<sup>223)</sup> That is,  $a < b$ ,  $a == b$ , and  $a > b$  might all be false.

```

constexpr operator weak_equality() const noexcept;

2   Returns: value == 0 ? weak_equality::equivalent : weak_equality::nonequivalent. [Note:
   The result is independent of the is_ordered member. —end note]

constexpr bool operator==(partial_ordering v, unspecified) noexcept;
constexpr bool operator< (partial_ordering v, unspecified) noexcept;
constexpr bool operator<=(partial_ordering v, unspecified) noexcept;
constexpr bool operator> (partial_ordering v, unspecified) noexcept;
constexpr bool operator>=(partial_ordering v, unspecified) noexcept;

3   Returns: For operator@, v.is_ordered && v.value @ 0.

constexpr bool operator==(unspecified, partial_ordering v) noexcept;
constexpr bool operator< (unspecified, partial_ordering v) noexcept;
constexpr bool operator<=(unspecified, partial_ordering v) noexcept;
constexpr bool operator> (unspecified, partial_ordering v) noexcept;
constexpr bool operator>=(unspecified, partial_ordering v) noexcept;

4   Returns: For operator@, v.is_ordered && 0 @ v.value.

constexpr bool operator!=(partial_ordering v, unspecified) noexcept;
constexpr bool operator!=(unspecified, partial_ordering v) noexcept;

5   Returns: For operator@, !v.is_ordered || v.value != 0.

```

### 21.10.2.5 Class weak\_ordering

[**cmp.weakord**]

- <sup>1</sup> The `weak_ordering` type is typically used as the result type of a three-way comparison operator (??) that (a) admits all of the six two-way comparison operators (??, ??), and (b) does not imply substitutability.

```

namespace std {

    class weak_ordering {
        int value; // exposition only

        // exposition-only constructors
        explicit constexpr weak_ordering(eq v) noexcept : value(int(v)) {} // exposition only
        explicit constexpr weak_ordering(ord v) noexcept : value(int(v)) {} // exposition only

        public:
            // valid values
            static const weak_ordering less;
            static const weak_ordering equivalent;
            static const weak_ordering greater;

            // conversions
            constexpr operator weak_equality() const noexcept;
            constexpr operator partial_ordering() const noexcept;

            // comparisons
            friend constexpr bool operator==(weak_ordering v, unspecified) noexcept;
            friend constexpr bool operator!=(weak_ordering v, unspecified) noexcept;
            friend constexpr bool operator< (weak_ordering v, unspecified) noexcept;
            friend constexpr bool operator<=(weak_ordering v, unspecified) noexcept;
            friend constexpr bool operator> (weak_ordering v, unspecified) noexcept;
            friend constexpr bool operator>=(weak_ordering v, unspecified) noexcept;
    };
}

```

```

        friend constexpr bool operator>=(weak_ordering v, unspecified) noexcept;
        friend constexpr bool operator==(unspecified, weak_ordering v) noexcept;
        friend constexpr bool operator!=(unspecified, weak_ordering v) noexcept;
        friend constexpr bool operator< (unspecified, weak_ordering v) noexcept;
        friend constexpr bool operator<=(unspecified, weak_ordering v) noexcept;
        friend constexpr bool operator> (unspecified, weak_ordering v) noexcept;
        friend constexpr bool operator>=(unspecified, weak_ordering v) noexcept;
    };

// valid values' definitions
inline constexpr weak_ordering weak_ordering::less(ord::less);
inline constexpr weak_ordering weak_ordering::equivalent(eq::equivalent);
inline constexpr weak_ordering weak_ordering::greater(ord::greater);
}

constexpr operator weak_equality() const noexcept;

2     Returns: value == 0 ? weak_equality::equivalent : weak_equality::nonequivalent.

constexpr operator partial_ordering() const noexcept;

3     Returns:

        value == 0 ? partial_ordering::equivalent :
        value < 0 ? partial_ordering::less :
                    partial_ordering::greater

constexpr bool operator==(weak_ordering v, unspecified) noexcept;
constexpr bool operator!=(weak_ordering v, unspecified) noexcept;
constexpr bool operator< (weak_ordering v, unspecified) noexcept;
constexpr bool operator<=(weak_ordering v, unspecified) noexcept;
constexpr bool operator> (weak_ordering v, unspecified) noexcept;
constexpr bool operator>=(weak_ordering v, unspecified) noexcept;

4     Returns: v.value @ 0 for operator@.

constexpr bool operator==(unspecified, weak_ordering v) noexcept;
constexpr bool operator!=(unspecified, weak_ordering v) noexcept;
constexpr bool operator< (unspecified, weak_ordering v) noexcept;
constexpr bool operator<=(unspecified, weak_ordering v) noexcept;
constexpr bool operator> (unspecified, weak_ordering v) noexcept;
constexpr bool operator>=(unspecified, weak_ordering v) noexcept;

5     Returns: 0 @ v.value for operator@.

```

### 21.10.2.6 Class `strong_ordering`

[`cmp.strongord`]

- <sup>1</sup> The `strong_ordering` type is typically used as the result type of a three-way comparison operator (??) that (a) admits all of the six two-way comparison operators (??, ??), and (b) does imply substitutability.

```

namespace std {
    class strong_ordering {
        int value; // exposition only

        // exposition-only constructors
        explicit constexpr strong_ordering(eq v) noexcept : value(int(v)) {} // exposition only
    }
}

```

```

explicit constexpr strong_ordering(ord v) noexcept : value(int(v)) {} // exposition only

public:
    // valid values
    static const strong_ordering less;
    static const strong_ordering equal;
    static const strong_ordering equivalent;
    static const strong_ordering greater;

    // conversions
    constexpr operator weak_equality() const noexcept;
    constexpr operator strong_equality() const noexcept;
    constexpr operator partial_ordering() const noexcept;
    constexpr operator weak_ordering() const noexcept;

    // comparisons
    friend constexpr bool operator==(strong_ordering v, unspecified) noexcept;
    friend constexpr bool operator!=(strong_ordering v, unspecified) noexcept;
    friend constexpr bool operator< (strong_ordering v, unspecified) noexcept;
    friend constexpr bool operator<=(strong_ordering v, unspecified) noexcept;
    friend constexpr bool operator> (strong_ordering v, unspecified) noexcept;
    friend constexpr bool operator>=(strong_ordering v, unspecified) noexcept;
    friend constexpr bool operator==(unspecified, strong_ordering v) noexcept;
    friend constexpr bool operator!=(unspecified, strong_ordering v) noexcept;
    friend constexpr bool operator< (unspecified, strong_ordering v) noexcept;
    friend constexpr bool operator<=(unspecified, strong_ordering v) noexcept;
    friend constexpr bool operator> (unspecified, strong_ordering v) noexcept;
    friend constexpr bool operator>=(unspecified, strong_ordering v) noexcept;
};

// valid values' definitions
inline constexpr strong_ordering strong_ordering::less(ord::less);
inline constexpr strong_ordering strong_ordering::equal(eq::equal);
inline constexpr strong_ordering strong_ordering::equivalent(eq::equivalent);
inline constexpr strong_ordering strong_ordering::greater(ord::greater);
}

constexpr operator weak_equality() const noexcept;
2     Returns: value == 0 ? weak_equality::equivalent : weak_equality::nonequivalent.

constexpr operator strong_equality() const noexcept;
3     Returns: value == 0 ? strong_equality::equal : strong_equality::nonequal.

constexpr operator partial_ordering() const noexcept;
4     Returns:
        value == 0 ? partial_ordering::equivalent :
        value < 0  ? partial_ordering::less :
                    partial_ordering::greater

```

```

constexpr operator weak_ordering() const noexcept;

5   Returns:

    value == 0 ? weak_ordering::equivalent :
    value < 0 ? weak_ordering::less :
                weak_ordering::greater

constexpr bool operator==(strong_ordering v, unspecified) noexcept;
constexpr bool operator!=(strong_ordering v, unspecified) noexcept;
constexpr bool operator< (strong_ordering v, unspecified) noexcept;
constexpr bool operator<=(strong_ordering v, unspecified) noexcept;
constexpr bool operator> (strong_ordering v, unspecified) noexcept;
constexpr bool operator>=(strong_ordering v, unspecified) noexcept;

6   Returns: v.value @ 0 for operator@.

constexpr bool operator==(unspecified, strong_ordering v) noexcept;
constexpr bool operator!=(unspecified, strong_ordering v) noexcept;
constexpr bool operator< (unspecified, strong_ordering v) noexcept;
constexpr bool operator<=(unspecified, strong_ordering v) noexcept;
constexpr bool operator> (unspecified, strong_ordering v) noexcept;
constexpr bool operator>=(unspecified, strong_ordering v) noexcept;

7   Returns: 0 @ v.value for operator@.

```

### 21.10.3 Class template common\_comparison\_category

[cmp.common]

- <sup>1</sup> The type `common_comparison_category` provides an alias for the strongest comparison category to which all of the template arguments can be converted. [ *Note:* A comparison category type is stronger than another if they are distinct types and an instance of the former can be converted to an instance of the latter. — *end note* ]

```

template<class... Ts>
struct common_comparison_category {
    using type = see below;
};

```

- <sup>2</sup> Remarks: The member `typedef-name` `type` denotes the common comparison type (??) of `Ts...`, the expanded parameter pack. [ *Note:* This is well-defined even if the expansion is empty or includes a type that is not a comparison category type. — *end note* ]

### 21.10.4 Comparison algorithms

[cmp.alg]

```
template<class T> constexpr strong_ordering strong_order(const T& a, const T& b);
```

- <sup>1</sup> Effects: Compares two values and produces a result of type `strong_ordering`:

- (1.1) — If `numeric_limits<T>::is_iec559` is `true`, returns a result of type `strong_ordering` that is consistent with the `totalOrder` operation as specified in ISO/IEC/IEEE 60559.
- (1.2) — Otherwise, returns `a <= b` if that expression is well-formed and convertible to `strong_ordering`.
- (1.3) — Otherwise, if the expression `a <= b` is well-formed, then the function is defined as deleted.
- (1.4) — Otherwise, if the expressions `a == b` and `a < b` are each well-formed and convertible to `bool`, then

- (1.4.1) — if  $a == b$  is true, returns `strong_ordering::equal`;
- (1.4.2) — otherwise, if  $a < b$  is true, returns `strong_ordering::less`;
- (1.4.3) — otherwise, returns `strong_ordering::greater`.
- (1.5) — Otherwise, the function is defined as deleted.

```
template<class T> constexpr weak_ordering weak_order(const T& a, const T& b);
```

2     *Effects:* Compares two values and produces a result of type `weak_ordering`:

- (2.1) — Returns  $a \leqslant b$  if that expression is well-formed and convertible to `weak_ordering`.
- (2.2) — Otherwise, if the expression  $a \leqslant b$  is well-formed, then the function is defined as deleted.
- (2.3) — Otherwise, if the expressions  $a == b$  and  $a < b$  are each well-formed and convertible to `bool`, then
  - (2.3.1) — if  $a == b$  is true, returns `weak_ordering::equivalent`;
  - (2.3.2) — otherwise, if  $a < b$  is true, returns `weak_ordering::less`;
  - (2.3.3) — otherwise, returns `weak_ordering::greater`.
- (2.4) — Otherwise, the function is defined as deleted.

```
template<class T> constexpr partial_ordering partial_order(const T& a, const T& b);
```

3     *Effects:* Compares two values and produces a result of type `partial_ordering`:

- (3.1) — Returns  $a \leqslant b$  if that expression is well-formed and convertible to `partial_ordering`.
- (3.2) — Otherwise, if the expression  $a \leqslant b$  is well-formed, then the function is defined as deleted.
- (3.3) — Otherwise, if the expressions  $a == b$  and  $a < b$  are each well-formed and convertible to `bool`, then
  - (3.3.1) — if  $a == b$  is true, returns `partial_ordering::equivalent`;
  - (3.3.2) — otherwise, if  $a < b$  is true, returns `partial_ordering::less`;
  - (3.3.3) — otherwise, returns `partial_ordering::greater`.
- (3.4) — Otherwise, the function is defined as deleted.

```
template<class T> constexpr strong_equality strong_equal(const T& a, const T& b);
```

4     *Effects:* Compares two values and produces a result of type `strong_equality`:

- (4.1) — Returns  $a \leqslant b$  if that expression is well-formed and convertible to `strong_equality`.
- (4.2) — Otherwise, if the expression  $a \leqslant b$  is well-formed, then the function is defined as deleted.
- (4.3) — Otherwise, if the expression  $a == b$  is well-formed and convertible to `bool`, then
  - (4.3.1) — if  $a == b$  is true, returns `strong_equality::equal`;
  - (4.3.2) — otherwise, returns `strong_equality::nonequal`.
- (4.4) — Otherwise, the function is defined as deleted.

```
template<class T> constexpr weak_equality weak_equal(const T& a, const T& b);
```

5     *Effects:* Compares two values and produces a result of type `weak_equality`:

- (5.1) — Returns  $a \leqslant b$  if that expression is well-formed and convertible to `weak_equality`.
- (5.2) — Otherwise, if the expression  $a \leqslant b$  is well-formed, then the function is defined as deleted.

- (5.3) — Otherwise, if the expression `a == b` is well-formed and convertible to `bool`, then
  - (5.3.1) — if `a == b` is `true`, returns `weak_equality::equivalent`;
  - (5.3.2) — otherwise, returns `weak_equality::nonequivalent`.
- (5.4) — Otherwise, the function is defined as deleted.

## 21.11 Other runtime support

[support.runtime]

- <sup>1</sup> Headers `<csetjmp>` (nonlocal jumps), `<csignal>` (signal handling), `<cstdarg>` (variable arguments), and `<cstdlib>` (runtime environment `getenv`, `system`), provide further compatibility with C code.
- 2 Calls to the function `getenv` (??) shall not introduce a data race (??) provided that nothing modifies the environment. [ *Note*: Calls to the POSIX functions `setenv` and `putenv` modify the environment. — *end note* ]
- 3 A call to the `setlocale` function (??) may introduce a data race with other calls to the `setlocale` function or with calls to functions that are affected by the current C locale. The implementation shall behave as if no library function other than `locale::global` calls the `setlocale` function.

### 21.11.1 Header `<cstdarg>` synopsis

[cstdarg.syn]

```
namespace std {
    using va_list = see below;
}

#define va_arg(V, P) see below
#define va_copy(VDST, VSRC) see below
#define va_end(V) see below
#define va_start(V, P) see below
```

- <sup>1</sup> The contents of the header `<cstdarg>` are the same as the C standard library header `<stdarg.h>`, with the following changes: The restrictions that ISO C places on the second parameter to the `va_start` macro in header `<stdarg.h>` are different in this document. The parameter `parmN` is the rightmost parameter in the variable parameter list of the function definition (the one just before the `...`).<sup>224</sup> If the parameter `parmN` is a pack expansion (??) or an entity resulting from a lambda capture (??), the program is ill-formed, no diagnostic required. If the parameter `parmN` is of a reference type, or of a type that is not compatible with the type that results when passing an argument for which there is no parameter, the behavior is undefined.

SEE ALSO: ISO C 7.16.1.1

### 21.11.2 Header `<csetjmp>` synopsis

[csetjmp.syn]

```
namespace std {
    using jmp_buf = see below;
    [[noreturn]] void longjmp(jmp_buf env, int val);
}

#define setjmp(env) see below
```

- <sup>1</sup> The contents of the header `<csetjmp>` are the same as the C standard library header `<setjmp.h>`.

---

<sup>224</sup>) Note that `va_start` is required to work as specified even if unary `operator&` is overloaded for the type of `parmN`.

- <sup>2</sup> The function signature `longjmp(jmp_buf jbuf, int val)` has more restricted behavior in this document. A `setjmp/longjmp` call pair has undefined behavior if replacing the `setjmp` and `longjmp` by `catch` and `throw` would invoke any non-trivial destructors for any automatic objects.

SEE ALSO: ISO C 7.13

### 21.11.3 Header <csignal> synopsis

[`csignal.syn`]

```
namespace std {
    using sig_atomic_t = see below;

    // ??, signal handlers
    extern "C" using signal-handler = void(int); // exposition only
    signal-handler* signal(int sig, signal-handler* func);

    int raise(int sig);
}

#define SIG_DFL see below
#define SIG_ERR see below
#define SIG_IGN see below
#define SIGABRT see below
#define SIGFPE see below
#define SIGILL see below
#define SIGINT see below
#define SIGSEGV see below
#define SIGTERM see below
```

- <sup>1</sup> The contents of the header <csignal> are the same as the C standard library header <`signal.h`>.

### 21.11.4 Signal handlers

[`support.signal`]

- <sup>1</sup> A call to the function `signal` synchronizes with any resulting invocation of the signal handler so installed.
- <sup>2</sup> A *plain lock-free atomic operation* is an invocation of a function `f` from ??, such that:
- (2.1) — `f` is the function `atomic_is_lock_free()`, or
  - (2.2) — `f` is the member function `is_lock_free()`, or
  - (2.3) — `f` is a non-static member function invoked on an object `A`, such that `A.is_lock_free()` yields `true`, or
  - (2.4) — `f` is a non-member function, and for every pointer-to-atomic argument `A` passed to `f`, `atomic_is_lock_free(A)` yields `true`.
- <sup>3</sup> An evaluation is *signal-safe* unless it includes one of the following:
- (3.1) — a call to any standard library function, except for plain lock-free atomic operations and functions explicitly identified as signal-safe. [ *Note*: This implicitly excludes the use of `new` and `delete` expressions that rely on a library-provided memory allocator. — *end note* ]
  - (3.2) — an access to an object with thread storage duration;
  - (3.3) — a `dynamic_cast` expression;
  - (3.4) — throwing of an exception;
  - (3.5) — control entering a *try-block* or *function-try-block*;

- (3.6) — initialization of a variable with static storage duration requiring dynamic initialization (??, ??)<sup>225</sup>; or
- (3.7) — waiting for the completion of the initialization of a variable with static storage duration (??).

A signal handler invocation has undefined behavior if it includes an evaluation that is not signal-safe.

- <sup>4</sup> The function `signal` is signal-safe if it is invoked with the first argument equal to the signal number corresponding to the signal that caused the invocation of the handler.

SEE ALSO: ISO C 7.14

---

<sup>225</sup>) Such initialization might occur because it is the first odr-use (??) of that variable.

## 22 Diagnostics library [diagnostics]

### 22.1 General

[diagnostics.general]

- <sup>1</sup> This Clause describes components that C++ programs may use to detect and report error conditions.
- <sup>2</sup> The following subclauses describe components for reporting several kinds of exceptional conditions, documenting program assertions, and a global variable for error number codes, as summarized in Table ??.

Table 33 — Diagnostics library summary

	Subclause	Header(s)
??	Exception classes	<stdexcept>
??	Assertions	<cassert>
??	Error numbers	<cerrno>
??	System error support	<system_error>

### 22.2 Exception classes

[std.exceptions]

- <sup>1</sup> The C++ standard library provides classes to be used to report certain errors (??) in C++ programs. In the error model reflected in these classes, errors are divided into two broad categories: *logic* errors and *runtime* errors.
- <sup>2</sup> The distinguishing characteristic of logic errors is that they are due to errors in the internal logic of the program. In theory, they are preventable.
- <sup>3</sup> By contrast, runtime errors are due to events beyond the scope of the program. They cannot be easily predicted in advance. The header <stdexcept> defines several types of predefined exceptions for reporting errors in a C++ program. These exceptions are related by inheritance.

#### 22.2.1 Header <stdexcept> synopsis

[stdexcept.syn]

```
namespace std {
    class logic_error;
    class domain_error;
    class invalid_argument;
    class length_error;
    class out_of_range;
    class runtime_error;
    class range_error;
    class overflow_error;
    class underflow_error;
}
```

#### 22.2.2 Class logic\_error

[logic.error]

```
namespace std {
    class logic_error : public exception {
    public:
        explicit logic_error(const string& what_arg);
        explicit logic_error(const char* what_arg);
    };
}
```

```
    };
}
```

- <sup>1</sup> The class `logic_error` defines the type of objects thrown as exceptions to report errors presumably detectable before the program executes, such as violations of logical preconditions or class invariants.

`logic_error(const string& what_arg);`

- <sup>2</sup> *Effects:* Constructs an object of class `logic_error`.

- <sup>3</sup> *Postconditions:* `strcmp(what(), what_arg.c_str()) == 0.`

`logic_error(const char* what_arg);`

- <sup>4</sup> *Effects:* Constructs an object of class `logic_error`.

- <sup>5</sup> *Postconditions:* `strcmp(what(), what_arg) == 0.`

### 22.2.3 Class `domain_error`

[`domain.error`]

```
namespace std {
    class domain_error : public logic_error {
        public:
            explicit domain_error(const string& what_arg);
            explicit domain_error(const char* what_arg);
    };
}
```

- <sup>1</sup> The class `domain_error` defines the type of objects thrown as exceptions by the implementation to report domain errors.

`domain_error(const string& what_arg);`

- <sup>2</sup> *Effects:* Constructs an object of class `domain_error`.

- <sup>3</sup> *Postconditions:* `strcmp(what(), what_arg.c_str()) == 0.`

`domain_error(const char* what_arg);`

- <sup>4</sup> *Effects:* Constructs an object of class `domain_error`.

- <sup>5</sup> *Postconditions:* `strcmp(what(), what_arg) == 0.`

### 22.2.4 Class `invalid_argument`

[`invalid.argument`]

```
namespace std {
    class invalid_argument : public logic_error {
        public:
            explicit invalid_argument(const string& what_arg);
            explicit invalid_argument(const char* what_arg);
    };
}
```

- <sup>1</sup> The class `invalid_argument` defines the type of objects thrown as exceptions to report an invalid argument.

`invalid_argument(const string& what_arg);`

- <sup>2</sup> *Effects:* Constructs an object of class `invalid_argument`.

- <sup>3</sup> *Postconditions:* `strcmp(what(), what_arg.c_str()) == 0.`

```
invalid_argument(const char* what_arg);

4   Effects: Constructs an object of class invalid_argument.

5   Postconditions: strcmp(what(), what_arg) == 0.
```

### 22.2.5 Class length\_error

[length.error]

```
namespace std {

    class length_error : public logic_error {

        public:

            explicit length_error(const string& what_arg);
            explicit length_error(const char* what_arg);

    };
}
```

- <sup>1</sup> The class `length_error` defines the type of objects thrown as exceptions to report an attempt to produce an object whose length exceeds its maximum allowable size.

```
length_error(const string& what_arg);

2   Effects: Constructs an object of class length_error.

3   Postconditions: strcmp(what(), what_arg.c_str()) == 0.

length_error(const char* what_arg);

4   Effects: Constructs an object of class length_error.

5   Postconditions: strcmp(what(), what_arg) == 0.
```

### 22.2.6 Class out\_of\_range

[out.of.range]

```
namespace std {

    class out_of_range : public logic_error {

        public:

            explicit out_of_range(const string& what_arg);
            explicit out_of_range(const char* what_arg);

    };
}
```

- <sup>1</sup> The class `out_of_range` defines the type of objects thrown as exceptions to report an argument value not in its expected range.

```
out_of_range(const string& what_arg);

2   Effects: Constructs an object of class out_of_range.

3   Postconditions: strcmp(what(), what_arg.c_str()) == 0.

out_of_range(const char* what_arg);

4   Effects: Constructs an object of class out_of_range.

5   Postconditions: strcmp(what(), what_arg) == 0.
```

### 22.2.7 Class runtime\_error

[runtime.error]

```
namespace std {

    class runtime_error : public exception {

        public:
```

```

    explicit runtime_error(const string& what_arg);
    explicit runtime_error(const char* what_arg);
};

}

```

- <sup>1</sup> The class `runtime_error` defines the type of objects thrown as exceptions to report errors presumably detectable only when the program executes.

`runtime_error(const string& what_arg);`

- <sup>2</sup> *Effects:* Constructs an object of class `runtime_error`.

- <sup>3</sup> *Postconditions:* `strcmp(what(), what_arg.c_str()) == 0.`

`runtime_error(const char* what_arg);`

- <sup>4</sup> *Effects:* Constructs an object of class `runtime_error`.

- <sup>5</sup> *Postconditions:* `strcmp(what(), what_arg) == 0.`

## 22.2.8 Class `range_error`

[`range.error`]

```

namespace std {
    class range_error : public runtime_error {
        public:
            explicit range_error(const string& what_arg);
            explicit range_error(const char* what_arg);
    };
}

```

- <sup>1</sup> The class `range_error` defines the type of objects thrown as exceptions to report range errors in internal computations.

`range_error(const string& what_arg);`

- <sup>2</sup> *Effects:* Constructs an object of class `range_error`.

- <sup>3</sup> *Postconditions:* `strcmp(what(), what_arg.c_str()) == 0.`

`range_error(const char* what_arg);`

- <sup>4</sup> *Effects:* Constructs an object of class `range_error`.

- <sup>5</sup> *Postconditions:* `strcmp(what(), what_arg) == 0.`

## 22.2.9 Class `overflow_error`

[`overflow.error`]

```

namespace std {
    class overflow_error : public runtime_error {
        public:
            explicit overflow_error(const string& what_arg);
            explicit overflow_error(const char* what_arg);
    };
}

```

- <sup>1</sup> The class `overflow_error` defines the type of objects thrown as exceptions to report an arithmetic overflow error.

`overflow_error(const string& what_arg);`

- <sup>2</sup> *Effects:* Constructs an object of class `overflow_error`.

3       *Postconditions:* `strcmp(what(), what_arg.c_str()) == 0.`  
       *overflow\_error(const char\* what\_arg);*  
 4       *Effects:* Constructs an object of class `overflow_error`.  
 5       *Postconditions:* `strcmp(what(), what_arg) == 0.`

### 22.2.10 Class `underflow_error`

[`underflow.error`]

```
namespace std {
    class underflow_error : public runtime_error {
public:
    explicit underflow_error(const string& what_arg);
    explicit underflow_error(const char* what_arg);
};
```

1 The class `underflow_error` defines the type of objects thrown as exceptions to report an arithmetic underflow error.

`underflow_error(const string& what_arg);`  
 2       *Effects:* Constructs an object of class `underflow_error`.  
 3       *Postconditions:* `strcmp(what(), what_arg.c_str()) == 0.`  
  
`underflow_error(const char* what_arg);`  
 4       *Effects:* Constructs an object of class `underflow_error`.  
 5       *Postconditions:* `strcmp(what(), what_arg) == 0.`

## 22.3 Assertions

[`assertions`]

1 The header `<cassert>` provides a macro for documenting C++ program assertions and a mechanism for disabling the assertion checks.

### 22.3.1 Header `<cassert>` synopsis

[`cassert.syn`]

```
#define assert(E) see below
```

1 The contents are the same as the C standard library header `<assert.h>`, except that a macro named `static_assert` is not defined.

SEE ALSO: ISO C 7.2

### 22.3.2 The `assert` macro

[`assertions.assert`]

1 An expression `assert(E)` is a constant subexpression (??), if  
 (1.1) — `NDEBUG` is defined at the point where `assert` is last defined or redefined, or  
 (1.2) — `E` contextually converted to `bool` (??) is a constant subexpression that evaluates to the value `true`.

## 22.4 Error numbers

[`errno`]

1 The contents of the header `<cerrno>` are the same as the POSIX header `<errno.h>`, except that `errno` shall be defined as a macro. [ *Note:* The intent is to remain in close alignment with the POSIX standard. — *end note* ] A separate `errno` value shall be provided for each thread.

### 22.4.1 Header <cerrno> synopsis

[**cerrno.syn**]

```
#define errno see below

#define E2BIG see below
#define EACCES see below
#define EADDRINUSE see below

```

<sup>1</sup> The meaning of the macros in this header is defined by the POSIX standard.

SEE ALSO: ISO C 7.5

## 22.5 System error support

[syserr]

- 1 This subclause describes components that the standard library and C++ programs may use to report error conditions originating from the operating system or other low-level application program interfaces.
- 2 Components described in this subclause shall not change the value of `errno` (??). Implementations should leave the error states provided by other libraries unchanged.

### 22.5.1 Header <system\_error> synopsis

[system\_error.syn]

```
namespace std {
    class error_category;
    const error_category& generic_category() noexcept;
    const error_category& system_category() noexcept;
```

```

class error_code;
class error_condition;
class system_error;

template<class T>
inline constexpr bool is_error_condition_enum_v = is_error_condition_enum<T>::value;
}

```

- <sup>1</sup> The value of each `enum errc` constant shall be the same as the value of the `<cerrno>` macro shown in the above synopsis. Whether or not the `<system_error>` implementation exposes the `<cerrno>` macros is unspecified.
- <sup>2</sup> The `is_error_code_enum` and `is_error_condition_enum` may be specialized for user-defined types to indicate that such types are eligible for `class error_code` and `class error_condition` automatic conversions, respectively.

## 22.5.2 Class `error_category`

[syserr.errcat]

### 22.5.2.1 Class `error_category` overview

[syserr.errcat.overview]

- <sup>1</sup> The class `error_category` serves as a base class for types used to identify the source and encoding of a particular category of error code. Classes may be derived from `error_category` to support categories of errors in addition to those defined in this document. Such classes shall behave as specified in this subclause ???. [Note: `error_category` objects are passed by reference, and two such objects are equal if they have the same address. This means that applications using custom `error_category` types should create a single object of each such type. — end note]

```

namespace std {
    class error_category {
        public:
            constexpr error_category() noexcept;
            virtual ~error_category();
            error_category(const error_category&) = delete;
    };
}
```

```

        error_category& operator=(const error_category&) = delete;
        virtual const char* name() const noexcept = 0;
        virtual error_condition default_error_condition(int ev) const noexcept;
        virtual bool equivalent(int code, const error_condition& condition) const noexcept;
        virtual bool equivalent(const error_code& code, int condition) const noexcept;
        virtual string message(int ev) const = 0;

        bool operator==(const error_category& rhs) const noexcept;
        bool operator!=(const error_category& rhs) const noexcept;
        bool operator<(const error_category& rhs) const noexcept;
    };

    const error_category& generic_category() noexcept;
    const error_category& system_category() noexcept;
}

```

**22.5.2.2 Class `error_category` virtual members**

[syserr.errcat.virtuals]

```
virtual ~error_category();
```

1     *Effects:* Destroys an object of class `error_category`.

```
virtual const char* name() const noexcept = 0;
```

2     *Returns:* A string naming the error category.

```
virtual error_condition default_error_condition(int ev) const noexcept;
```

3     *Returns:* `error_condition(ev, *this)`.

```
virtual bool equivalent(int code, const error_condition& condition) const noexcept;
```

4     *Returns:* `default_error_condition(code) == condition`.

```
virtual bool equivalent(const error_code& code, int condition) const noexcept;
```

5     *Returns:* `*this == code.category() && code.value() == condition`.

```
virtual string message(int ev) const = 0;
```

6     *Returns:* A string that describes the error condition denoted by `ev`.

**22.5.2.3 Class `error_category` non-virtual members**

[syserr.errcat.nonvirtuals]

```
constexpr error_category() noexcept;
```

1     *Effects:* Constructs an object of class `error_category`.

```
bool operator==(const error_category& rhs) const noexcept;
```

2     *Returns:* `this == &rhs`.

```
bool operator!=(const error_category& rhs) const noexcept;
```

3     *Returns:* `!(*this == rhs)`.

```
bool operator<(const error_category& rhs) const noexcept;
```

4     *Returns:* `less<const error_category*>()(this, &rhs)`.

[*Note:* `less` (??) provides a total ordering for pointers. —end note]

#### 22.5.2.4 Program defined classes derived from `error_category` [syserr.errcat.derived]

```
virtual const char* name() const noexcept = 0;

1   Returns: A string naming the error category.

virtual error_condition default_error_condition(int ev) const noexcept;

2   Returns: An object of type error_condition that corresponds to ev.

virtual bool equivalent(int code, const error_condition& condition) const noexcept;

3   Returns: true if, for the category of error represented by *this, code is considered equivalent to condition; otherwise, false.

virtual bool equivalent(const error_code& code, int condition) const noexcept;

4   Returns: true if, for the category of error represented by *this, code is considered equivalent to condition; otherwise, false.
```

#### 22.5.2.5 Error category objects [syserr.errcat.objects]

```
const error_category& generic_category() noexcept;

1   Returns: A reference to an object of a type derived from class error_category. All calls to this function shall return references to the same object.

2   Remarks: The object's default_error_condition and equivalent virtual functions shall behave as specified for the class error_category. The object's name virtual function shall return a pointer to the string "generic".

const error_category& system_category() noexcept;

3   Returns: A reference to an object of a type derived from class error_category. All calls to this function shall return references to the same object.

4   Remarks: The object's equivalent virtual functions shall behave as specified for class error_category. The object's name virtual function shall return a pointer to the string "system". The object's default_error_condition virtual function shall behave as follows:
```

If the argument `ev` corresponds to a POSIX `errno` value `posv`, the function shall return `error_condition(posv, generic_category())`. Otherwise, the function shall return `error_condition(ev, system_category())`. What constitutes correspondence for any given operating system is unspecified.  
[*Note*: The number of potential system error codes is large and unbounded, and some may not correspond to any POSIX `errno` value. Thus implementations are given latitude in determining correspondence. — *end note*]

#### 22.5.3 Class `error_code` [syserr.errcode]

##### 22.5.3.1 Class `error_code` overview [syserr.errcode.overview]

- 1 The class `error_code` describes an object used to hold error code values, such as those originating from the operating system or other low-level application program interfaces. [*Note*: Class `error_code` is an adjunct to error reporting by exception. — *end note*]

```
namespace std {
    class error_code {
        public:
            // ??, constructors
```

```

    error_code() noexcept;
    error_code(int val, const error_category& cat) noexcept;
    template<class ErrorCodeEnum>
        error_code(ErrorCodeEnum e) noexcept;

    // ??, modifiers
    void assign(int val, const error_category& cat) noexcept;
    template<class ErrorCodeEnum>
        error_code& operator=(ErrorCodeEnum e) noexcept;
    void clear() noexcept;

    // ??, observers
    int value() const noexcept;
    const error_category& category() const noexcept;
    error_condition default_error_condition() const noexcept;
    string message() const;
    explicit operator bool() const noexcept;

private:
    int val_;                      // exposition only
    const error_category* cat_; // exposition only
};

// ??, non-member functions
error_code make_error_code(errc e) noexcept;

template<class charT, class traits>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const error_code& ec);
}

```

### 22.5.3.2 Class `error_code` constructors

[`syserr.errorcode.constructors`]

```

error_code() noexcept;

1   Effects: Constructs an object of type error_code.
2   Postconditions: val_ == 0 and cat_ == &system_category().

```

```

error_code(int val, const error_category& cat) noexcept;

3   Effects: Constructs an object of type error_code.
4   Postconditions: val_ == val and cat_ == &cat.

```

```

template<class ErrorCodeEnum>
error_code(ErrorCodeEnum e) noexcept;

5   Effects: Constructs an object of type error_code.
6   Postconditions: *this == make_error_code(e).
7   Remarks: This constructor shall not participate in overload resolution unless
             is_error_code_enum_v<ErrorCodeEnum> is true.

```

**22.5.3.3 Class error\_code modifiers**

[syserr.errcode.modifiers]

```
void assign(int val, const error_category& cat) noexcept;

1   Postconditions: val_ == val and cat_ == &cat.

template<class ErrorCodeEnum>
error_code& operator=(ErrorCodeEnum e) noexcept;

2   Postconditions: *this == make_error_code(e).

3   Returns: *this.

4   Remarks: This operator shall not participate in overload resolution unless
is_error_code_enum_v<ErrorCodeEnum> is true.

void clear() noexcept;

5   Postconditions: value() == 0 and category() == system_category().
```

**22.5.3.4 Class error\_code observers**

[syserr.errcode.observers]

```
int value() const noexcept;

1   Returns: val_.

const error_category& category() const noexcept;

2   Returns: *cat_.

error_condition default_error_condition() const noexcept;

3   Returns: category().default_error_condition(value()).

string message() const;

4   Returns: category().message(value()).

explicit operator bool() const noexcept;

5   Returns: value() != 0.
```

**22.5.3.5 Class error\_code non-member functions**

[syserr.errcode.nonmembers]

```
error_code make_error_code(errc e) noexcept;

1   Returns: error_code(static_cast<int>(e), generic_category()).

template<class charT, class traits>
basic_ostream<charT, traits>& operator<<(basic_ostream<charT, traits>& os, const error_code& ec);

2   Effects: As if by: os << ec.category().name() << ':' << ec.value();
```

**22.5.4 Class error\_condition**

[syserr.errcondition]

**22.5.4.1 Class error\_condition overview**

[syserr.errcondition.overview]

- <sup>1</sup> The class `error_condition` describes an object used to hold values identifying error conditions. [ *Note:* `error_condition` values are portable abstractions, while `error_code` values (??) are implementation specific. — *end note* ]

```

namespace std {
    class error_condition {
        public:
            // ??, constructors
            error_condition() noexcept;
            error_condition(int val, const error_category& cat) noexcept;
            template<class ErrorConditionEnum>
                error_condition(ErrorConditionEnum e) noexcept;

            // ??, modifiers
            void assign(int val, const error_category& cat) noexcept;
            template<class ErrorConditionEnum>
                error_condition& operator=(ErrorConditionEnum e) noexcept;
            void clear() noexcept;

            // ??, observers
            int value() const noexcept;
            const error_category& category() const noexcept;
            string message() const;
            explicit operator bool() const noexcept;

        private:
            int val_;                                // exposition only
            const error_category* cat_; // exposition only
        };
}

```

#### 22.5.4.2 Class `error_condition` constructors

[syserr.errcondition.constructors]

`error_condition()` noexcept;

1     *Effects:* Constructs an object of type `error_condition`.

2     *Postconditions:* `val_ == 0` and `cat_ == &generic_category()`.

`error_condition(int val, const error_category& cat)` noexcept;

3     *Effects:* Constructs an object of type `error_condition`.

4     *Postconditions:* `val_ == val` and `cat_ == &cat`.

`template<class ErrorConditionEnum>`

`error_condition(ErrorConditionEnum e)` noexcept;

5     *Effects:* Constructs an object of type `error_condition`.

6     *Postconditions:* `*this == make_error_condition(e)`.

7     *Remarks:* This constructor shall not participate in overload resolution unless `is_error_condition_enum_v<ErrorConditionEnum>` is true.

#### 22.5.4.3 Class `error_condition` modifiers

[syserr.errcondition.modifiers]

`void assign(int val, const error_category& cat)` noexcept;

1     *Postconditions:* `val_ == val` and `cat_ == &cat`.

```

template<class ErrorConditionEnum>
error_condition& operator=(ErrorConditionEnum e) noexcept;

2   Postconditions: *this == make_error_condition(e).

3   Returns: *this.

4   Remarks: This operator shall not participate in overload resolution unless
is_error_condition_enum_v<ErrorConditionEnum> is true.

void clear() noexcept;

5   Postconditions: value() == 0 and category() == generic_category().

```

**22.5.4.4 Class error\_condition observers**

[syserr.errcondition.observers]

```

int value() const noexcept;

1   Returns: val_.

const error_category& category() const noexcept;

2   Returns: *cat_.

string message() const;

3   Returns: category().message(value()).

explicit operator bool() const noexcept;

4   Returns: value() != 0.

```

**22.5.4.5 Class error\_condition non-member functions**

[syserr.errcondition.nonmembers]

```

error_condition make_error_condition(errc e) noexcept;

1   Returns: error_condition(static_cast<int>(e), generic_category()).

```

**22.5.5 Comparison functions**

[syserr.compare]

```

bool operator<(const error_code& lhs, const error_code& rhs) noexcept;

1   Returns:
        lhs.category() < rhs.category() ||
        (lhs.category() == rhs.category() && lhs.value() < rhs.value())

bool operator<(const error_condition& lhs, const error_condition& rhs) noexcept;

2   Returns:
        lhs.category() < rhs.category() ||
        (lhs.category() == rhs.category() && lhs.value() < rhs.value())

bool operator==(const error_code& lhs, const error_code& rhs) noexcept;

3   Returns:
        lhs.category() == rhs.category() && lhs.value() == rhs.value()

bool operator==(const error_code& lhs, const error_condition& rhs) noexcept;

4   Returns:
        lhs.category().equivalent(lhs.value(), rhs) || rhs.category().equivalent(lhs, rhs.value())

```

```

bool operator==(const error_condition& lhs, const error_code& rhs) noexcept;
5   Returns:
      rhs.category().equivalent(rhs.value(), lhs) || lhs.category().equivalent(rhs, lhs.value())

bool operator==(const error_condition& lhs, const error_condition& rhs) noexcept;
6   Returns:
      lhs.category() == rhs.category() && lhs.value() == rhs.value()

bool operator!=(const error_code& lhs, const error_code& rhs) noexcept;
bool operator!=(const error_code& lhs, const error_condition& rhs) noexcept;
bool operator!=(const error_condition& lhs, const error_code& rhs) noexcept;
bool operator!=(const error_condition& lhs, const error_condition& rhs) noexcept;

7   Returns: !(lhs == rhs).

```

## 22.5.6 System error hash support

[syserr.hash]

```

template<> struct hash<error_code>;
template<> struct hash<error_condition>;

```

1 The specializations are enabled (??).

## 22.5.7 Class system\_error

[syserr.syserr]

### 22.5.7.1 Class system\_error overview

[syserr.syserr.overview]

- 1 The class `system_error` describes an exception object used to report error conditions that have an associated error code. Such error conditions typically originate from the operating system or other low-level application program interfaces.
- 2 [Note: If an error represents an out-of-memory condition, implementations are encouraged to throw an exception object of type `bad_alloc` (??) rather than `system_error`. —end note]

```

namespace std {
    class system_error : public runtime_error {
        public:
            system_error(error_code ec, const string& what_arg);
            system_error(error_code ec, const char* what_arg);
            system_error(error_code ec);
            system_error(int ev, const error_category& ecat, const string& what_arg);
            system_error(int ev, const error_category& ecat, const char* what_arg);
            system_error(int ev, const error_category& ecat);
            const error_code& code() const noexcept;
            const char* what() const noexcept override;
    };
}

```

### 22.5.7.2 Class system\_error members

[syserr.syserr.members]

```
system_error(error_code ec, const string& what_arg);
```

1 *Effects:* Constructs an object of class `system_error`.

2 *Postconditions:* `code() == ec` and `string(what()).find(what_arg) != string::npos`.

```
system_error(error_code ec, const char* what_arg);

3   Effects: Constructs an object of class system_error.

4   Postconditions: code() == ec and string(what()).find(what_arg) != string::npos.

system_error(error_code ec);

5   Effects: Constructs an object of class system_error.

6   Postconditions: code() == ec.

system_error(int ev, const error_category& ecat, const string& what_arg);

7   Effects: Constructs an object of class system_error.

8   Postconditions: code() == error_code(ev, ecat) and
                     string(what()).find(what_arg) != string::npos.

system_error(int ev, const error_category& ecat, const char* what_arg);

9   Effects: Constructs an object of class system_error.

10  Postconditions: code() == error_code(ev, ecat) and
                     string(what()).find(what_arg) != string::npos.

system_error(int ev, const error_category& ecat);

11  Effects: Constructs an object of class system_error.

12  Postconditions: code() == error_code(ev, ecat).

const error_code& code() const noexcept;

13  Returns: ec or error_code(ev, ecat), from the constructor, as appropriate.

const char* what() const noexcept override;

14  Returns: An NTBS incorporating the arguments supplied in the constructor.

[Note: The returned NTBS might be the contents of what_arg + ":" + code.message(). — end
note]
```

# 23 General utilities library [utilities]

## 23.1 General [utilities.general]

- <sup>1</sup> This Clause describes utilities that are generally useful in C++ programs; some of these utilities are used by other elements of the C++ standard library. These utilities are summarized in Table ??.

Table 34 — General utilities library summary

Subclause	Header(s)
?? Utility components	<utility>
?? Compile-time integer sequences	<utility>
?? Pairs	<utility>
?? Tuples	<tuple>
?? Optional objects	<optional>
?? Variants	<variant>
?? Storage for any type	<any>
?? Fixed-size sequences of bits	<set>
?? Memory	<memory> <cstdlib>
?? Smart pointers	<memory>
?? Memory resources	<memory_resource>
?? Scoped allocators	<scoped_allocator>
?? Function objects	<functional>
?? Type traits	<type_traits>
?? Compile-time rational arithmetic	<ratio>
?? Time utilities	<chrono> <ctime>
?? Type indexes	<typeindex>
?? Execution policies	<execution>
?? Primitive numeric conversions	<charconv>

## 23.2 Utility components [utility]

- <sup>1</sup> This subclause contains some basic function and class templates that are used throughout the rest of the library.

### 23.2.1 Header <utility> synopsis [utility.syn]

```
#include <initializer_list> // see ???

namespace std {
    // ??, swap
    template<class T>
    void swap(T& a, T& b) noexcept(see below);
    template<class T, size_t N>
    void swap(T (&a)[N], T (&b)[N]) noexcept(is_nothrow_swappable_v<T>);

    // ??, exchange
    template<class T, class U = T>
    constexpr T exchange(T& obj, U&& new_val);
```

```

// ??, forward/move
template<class T>
    constexpr T&& forward(remove_reference_t<T>& t) noexcept;
template<class T>
    constexpr T&& forward(remove_reference_t<T>&& t) noexcept;
template<class T>
    constexpr remove_reference_t<T>&& move(T&&) noexcept;
template<class T>
    constexpr conditional_t<
        !is_nothrow_move_constructible_v<T> && is_copy_constructible_v<T>, const T&, T&&>
        move_if_noexcept(T& x) noexcept;

// ??, as_const
template<class T>
    constexpr add_const_t<T>& as_const(T& t) noexcept;
template<class T>
    void as_const(const T&&) = delete;

// ??, declval
template<class T>
    add_rvalue_reference_t<T> declval() noexcept; // as unevaluated operand

// ??, Compile-time integer sequences
template<class T, T...>
    struct integer_sequence;
template<size_t... I>
    using index_sequence = integer_sequence<size_t, I...>;

template<class T, T N>
    using make_integer_sequence = integer_sequence<T, see below>;
template<size_t N>
    using make_index_sequence = make_integer_sequence<size_t, N>;

template<class... T>
    using index_sequence_for = make_index_sequence<sizeof...(T)>;

// ??, class template pair
template<class T1, class T2>
    struct pair;

// ??, pair specialized algorithms
template<class T1, class T2>
    constexpr bool operator==(const pair<T1, T2>&, const pair<T1, T2>&);
template<class T1, class T2>
    constexpr bool operator< (const pair<T1, T2>&, const pair<T1, T2>&);
template<class T1, class T2>
    constexpr bool operator!=(const pair<T1, T2>&, const pair<T1, T2>&);
template<class T1, class T2>
    constexpr bool operator> (const pair<T1, T2>&, const pair<T1, T2>&);

```

```

template<class T1, class T2>
constexpr bool operator>=(const pair<T1, T2>&, const pair<T1, T2>&);

template<class T1, class T2>
constexpr bool operator<=(const pair<T1, T2>&, const pair<T1, T2>&);

template<class T1, class T2>
void swap(pair<T1, T2>& x, pair<T1, T2>& y) noexcept(noexcept(x.swap(y)));

template<class T1, class T2>
constexpr see below make_pair(T1&&, T2&&);

// ??, tuple-like access to pair
template<class T> class tuple_size;
template<size_t I, class T> class tuple_element;

template<class T1, class T2> struct tuple_size<pair<T1, T2>>;
template<size_t I, class T1, class T2> struct tuple_element<I, pair<T1, T2>>;

template<size_t I, class T1, class T2>
constexpr tuple_element_t<I, pair<T1, T2>>& get(pair<T1, T2>&) noexcept;
template<size_t I, class T1, class T2>
constexpr tuple_element_t<I, pair<T1, T2>>&& get(pair<T1, T2>&&) noexcept;
template<size_t I, class T1, class T2>
constexpr const tuple_element_t<I, pair<T1, T2>>& get(const pair<T1, T2>&) noexcept;
template<size_t I, class T1, class T2>
constexpr const tuple_element_t<I, pair<T1, T2>>&& get(const pair<T1, T2>&&) noexcept;
template<class T1, class T2>
constexpr T1& get(pair<T1, T2>& p) noexcept;
template<class T1, class T2>
constexpr const T1& get(const pair<T1, T2>& p) noexcept;
template<class T1, class T2>
constexpr T1&& get(pair<T1, T2>&& p) noexcept;
template<class T1, class T2>
constexpr const T1&& get(const pair<T1, T2>&& p) noexcept;
template<class T2, class T1>
constexpr T2& get(pair<T1, T2>& p) noexcept;
template<class T2, class T1>
constexpr const T2& get(const pair<T1, T2>& p) noexcept;
template<class T2, class T1>
constexpr T2&& get(pair<T1, T2>&& p) noexcept;
template<class T2, class T1>
constexpr const T2&& get(const pair<T1, T2>&& p) noexcept;

// ??, pair piecewise construction
struct piecewise_construct_t {
    explicit piecewise_construct_t() = default;
};

inline constexpr piecewise_construct_t piecewise_construct{};
template<class... Types> class tuple;           // defined in <tuple> (?)

```

```
// in-place construction
struct in_place_t {
    explicit in_place_t() = default;
};

inline constexpr in_place_t in_place{};

template<class T>
struct in_place_type_t {
    explicit in_place_type_t() = default;
};

template<class T> inline constexpr in_place_type_t<T> in_place_type{};

template<size_t I>
struct in_place_index_t {
    explicit in_place_index_t() = default;
};

template<size_t I> inline constexpr in_place_index_t<I> in_place_index{};

}
```

- <sup>1</sup> The header <utility> defines several types and function templates that are described in this Clause. It also defines the template **pair** and various function templates that operate on **pair** objects.
- <sup>2</sup> The type **chars\_format** is a bitmask type (??) with elements **scientific**, **fixed**, and **hex**.

### 23.2.2 swap

[utility.swap]

```
template<class T>
void swap(T& a, T& b) noexcept(see below);
```

- <sup>1</sup> *Remarks:* This function shall not participate in overload resolution unless **is\_move\_constructible\_v**<T> is **true** and **is\_move\_assignable\_v**<T> is **true**. The expression inside **noexcept** is equivalent to:
 

```
is_nothrow_move_constructible_v<T> && is_nothrow_move_assignable_v<T>
```
- <sup>2</sup> *Requires:* Type T shall be **MoveConstructible** (Table ??) and **MoveAssignable** (Table ??).
- <sup>3</sup> *Effects:* Exchanges values stored in two locations.

```
template<class T, size_t N>
void swap(T (&a)[N], T (&b)[N]) noexcept(is_nothrow_swappable_v<T>);
```

- <sup>4</sup> *Remarks:* This function shall not participate in overload resolution unless **is\_swappable\_v**<T> is **true**.
- <sup>5</sup> *Requires:* a[i] shall be swappable with (??) b[i] for all i in the range [0, N].
- <sup>6</sup> *Effects:* As if by **swap\_ranges**(a, a + N, b).

### 23.2.3 exchange

[utility.exchange]

```
template<class T, class U = T>
constexpr T exchange(T& obj, U&& new_val);
```

- <sup>1</sup> *Effects:* Equivalent to:
 

```
T old_val = std::move(obj);
obj = std::forward<U>(new_val);
return old_val;
```

### 23.2.4 Forward/move helpers

[forward]

- <sup>1</sup> The library provides templated helper functions to simplify applying move semantics to an lvalue and to simplify the implementation of forwarding functions. All functions specified in this subclause are signal-safe (??).

```
template<class T> constexpr T&& forward(remove_reference_t<T>& t) noexcept;
template<class T> constexpr T&& forward(remove_reference_t<T>&& t) noexcept;
```

<sup>2</sup> Returns: static\_cast<T&&>(t).

<sup>3</sup> Remarks: If the second form is instantiated with an lvalue reference type, the program is ill-formed.

<sup>4</sup> [ Example:

```
template<class T, class A1, class A2>
shared_ptr<T> factory(A1&& a1, A2&& a2) {
    return shared_ptr<T>(new T(std::forward<A1>(a1), std::forward<A2>(a2)));
}

struct A {
    A(int&, const double&);
};

void g() {
    shared_ptr<A> sp1 = factory<A>(2, 1.414); // error: 2 will not bind to int&
    int i = 2;
    shared_ptr<A> sp2 = factory<A>(i, 1.414); // OK
}
```

In the first call to `factory`, `A1` is deduced as `int`, so `2` is forwarded to `A`'s constructor as an rvalue. In the second call to `factory`, `A1` is deduced as `int&`, so `i` is forwarded to `A`'s constructor as an lvalue. In both cases, `A2` is deduced as `double`, so `1.414` is forwarded to `A`'s constructor as an rvalue. — end example ]

```
template<class T> constexpr remove_reference_t<T>&& move(T&& t) noexcept;
```

<sup>5</sup> Returns: static\_cast<remove\_reference\_t<T>&&>(t).

<sup>6</sup> [ Example:

```
template<class T, class A1>
shared_ptr<T> factory(A1&& a1) {
    return shared_ptr<T>(new T(std::forward<A1>(a1)));
}

struct A {
    A();
    A(const A&);      // copies from lvalues
    A(A&&);         // moves from rvalues
};

void g() {
    A a;
    shared_ptr<A> sp1 = factory<A>(a);           // "a" binds to A(const A&)
```

```
shared_ptr<A> sp1 = factory<A>(std::move(a));      // "a" binds to A(A&&)
}
```

In the first call to `factory`, `A1` is deduced as `A&`, so `a` is forwarded as a non-const lvalue. This binds to the constructor `A(const A&)`, which copies the value from `a`. In the second call to `factory`, because of the call `std::move(a)`, `A1` is deduced as `A`, so `a` is forwarded as an rvalue. This binds to the constructor `A(A&&)`, which moves the value from `a`. — *end example*

```
template<class T> constexpr conditional_t<
    !is_nothrow_move_constructible_v<T> && is_copy_constructible_v<T>, const T&, T&&>
move_if_noexcept(T& x) noexcept;
```

7     *Returns:* `std::move(x)`.

### 23.2.5 Function template `as_const`

[utility.as\_const]

```
template<class T> constexpr add_const_t<T>& as_const(T& t) noexcept;
```

1     *Returns:* `t`.

### 23.2.6 Function template `declval`

[declval]

- 1 The library provides the function template `declval` to simplify the definition of expressions which occur as unevaluated operands (??).

```
template<class T> add_rvalue_reference_t<T> declval() noexcept; // as unevaluated operand
```

2     *Remarks:* If this function is odr-used (??), the program is ill-formed.

3     *Remarks:* The template parameter `T` of `declval` may be an incomplete type.

4 [Example:

```
template<class To, class From> decltype(static_cast<To>(declval<From>())) convert(From&&);
```

declares a function template `convert` which only participates in overloading if the type `From` can be explicitly converted to type `To`. For another example see class template `common_type` (??). — *end example*

## 23.3 Compile-time integer sequences

[intseq]

### 23.3.1 In general

[intseq.general]

- 1 The library provides a class template that can represent an integer sequence. When used as an argument to a function template the parameter pack defining the sequence can be deduced and used in a pack expansion. [Note: The `index_sequence` alias template is provided for the common case of an integer sequence of type `size_t`; see also ???. — *end note*]

### 23.3.2 Class template `integer_sequence`

[intseq.intseq]

```
namespace std {
    template<class T, T... I>
    struct integer_sequence {
        using value_type = T;
        static constexpr size_t size() noexcept { return sizeof...(I); }
    };
}
```

- 1 `T` shall be an integer type.

### 23.3.3 Alias template `make_integer_sequence`

[intseq.make]

```
template<class T, T N>
using make_integer_sequence = integer_sequence<T, see below>;
```

- <sup>1</sup> If `N` is negative the program is ill-formed. The alias template `make_integer_sequence` denotes a specialization of `integer_sequence` with `N` template non-type arguments. The type `make_integer_sequence<T, N>` denotes the type `integer_sequence<T, 0, 1, ..., N-1>`. [Note: `make_integer_sequence<int, 0>` denotes the type `integer_sequence<int>` — end note]

## 23.4 Pairs

[pairs]

### 23.4.1 In general

[pairs.general]

- <sup>1</sup> The library provides a template for heterogeneous pairs of values. The library also provides a matching function template to simplify their construction and several templates that provide access to `pair` objects as if they were `tuple` objects (see ?? and ??).

### 23.4.2 Class template `pair`

[pairs.pair]

```
namespace std {
    template<class T1, class T2>
    struct pair {
        using first_type = T1;
        using second_type = T2;

        T1 first;
        T2 second;

        pair(const pair&) = default;
        pair(pair&&) = default;
        EXPLICIT constexpr pair();
        EXPLICIT constexpr pair(const T1& x, const T2& y);
        template<class U1, class U2> EXPLICIT constexpr pair(U1&& x, U2&& y);
        template<class U1, class U2> EXPLICIT constexpr pair(const pair<U1, U2>& p);
        template<class U1, class U2> EXPLICIT constexpr pair(pair<U1, U2>&& p);
        template<class... Args1, class... Args2>
            pair(piecewise_construct_t, tuple<Args1...> first_args, tuple<Args2...> second_args);

        pair& operator=(const pair& p);
        template<class U1, class U2> pair& operator=(const pair<U1, U2>& p);
        pair& operator=(pair&& p) noexcept(see below);
        template<class U1, class U2> pair& operator=(pair<U1, U2>&& p);

        void swap(pair& p) noexcept(see below);
    };

    template<class T1, class T2>
    pair(T1, T2) -> pair<T1, T2>;
}
```

- <sup>1</sup> Constructors and member functions of `pair` shall not throw exceptions unless one of the element-wise operations specified to be called for that operation throws an exception.

- <sup>2</sup> The defaulted move and copy constructor, respectively, of `pair` shall be a `constexpr` function if and only if all required element-wise initializations for copy and move, respectively, would satisfy the requirements for a `constexpr` function. The destructor of `pair` shall be a trivial destructor if `(is_trivially_destructible_v<T1> && is_trivially_destructible_v<T2>)` is true.

*EXPLICIT constexpr pair();*

- <sup>3</sup> *Effects:* Value-initializes `first` and `second`.

- <sup>4</sup> *Remarks:* This constructor shall not participate in overload resolution unless `is_default_constructible_v<first_type>` is true and `is_default_constructible_v<second_type>` is true. [ *Note:* This behavior can be implemented by a constructor template with default template arguments. — *end note* ] The constructor is explicit if and only if either `first_type` or `second_type` is not implicitly default-constructible. [ *Note:* This behavior can be implemented with a trait that checks whether a `const first_type&` or a `const second_type&` can be initialized with `{}`. — *end note* ]

*EXPLICIT constexpr pair(const T1& x, const T2& y);*

- <sup>5</sup> *Effects:* Initializes `first` with `x` and `second` with `y`.

- <sup>6</sup> *Remarks:* This constructor shall not participate in overload resolution unless `is_copy_constructible_v<first_type>` is true and `is_copy_constructible_v<second_type>` is true. The constructor is explicit if and only if `is_convertible_v<const first_type&, first_type>` is false or `is_convertible_v<const second_type&, second_type>` is false.

`template<class U1, class U2> EXPLICIT constexpr pair(U1&& x, U2&& y);`

- <sup>7</sup> *Effects:* Initializes `first` with `std::forward<U1>(x)` and `second` with `std::forward<U2>(y)`.

- <sup>8</sup> *Remarks:* This constructor shall not participate in overload resolution unless `is_constructible_v<first_type, U1&&>` is true and `is_constructible_v<second_type, U2&&>` is true. The constructor is explicit if and only if `is_convertible_v<U1&&, first_type>` is false or `is_convertible_v<U2&&, second_type>` is false.

`template<class U1, class U2> EXPLICIT constexpr pair(const pair<U1, U2>& p);`

- <sup>9</sup> *Effects:* Initializes members from the corresponding members of the argument.

- <sup>10</sup> *Remarks:* This constructor shall not participate in overload resolution unless `is_constructible_v<first_type, const U1&>` is true and `is_constructible_v<second_type, const U2&>` is true. The constructor is explicit if and only if `is_convertible_v<const U1&, first_type>` is false or `is_convertible_v<const U2&, second_type>` is false.

`template<class U1, class U2> EXPLICIT constexpr pair(pair<U1, U2>&& p);`

- <sup>11</sup> *Effects:* Initializes `first` with `std::forward<U1>(p.first)` and `second` with `std::forward<U2>(p.second)`.

- <sup>12</sup> *Remarks:* This constructor shall not participate in overload resolution unless `is_constructible_v<first_type, U1&&>` is true and `is_constructible_v<second_type, U2&&>` is true. The constructor is explicit if and only if `is_convertible_v<U1&&, first_type>` is false or `is_convertible_v<U2&&, second_type>` is false.

`template<class... Args1, class... Args2>`

```

pair(piecewise_construct_t, tuple<Args1...> first_args, tuple<Args2...> second_args);

13  Requires: is_constructible_v<first_type, Args1&&...> is true and is_constructible_v<second_type, Args2&&...> is true.

14  Effects: Initializes first with arguments of types Args1... obtained by forwarding the elements of first_args and initializes second with arguments of types Args2... obtained by forwarding the elements of second_args. (Here, forwarding an element x of type U within a tuple object means calling std::forward<U>(x).) This form of construction, whereby constructor arguments for first and second are each provided in a separate tuple object, is called piecewise construction.

pair& operator=(const pair& p);

15  Effects: Assigns p.first to first and p.second to second.

16  Remarks: This operator shall be defined as deleted unless is_copy_assignable_v<first_type> is true and is_copy_assignable_v<second_type> is true.

17  Returns: *this.

template<class U1, class U2> pair& operator=(const pair<U1, U2>& p);

18  Effects: Assigns p.first to first and p.second to second.

19  Remarks: This operator shall not participate in overload resolution unless is assignable_v<first_type&, const U1&> is true and is assignable_v<second_type&, const U2&> is true.

20  Returns: *this.

pair& operator=(pair&& p) noexcept(see below);

21  Effects: Assigns to first with std::forward<first_type>(p.first) and to second with std::forward<second_type>(p.second).

22  Remarks: This operator shall not participate in overload resolution unless is move assignable_v<first_type> is true and is move assignable_v<second_type> is true.

23  Remarks: The expression inside noexcept is equivalent to:
    is_nothrow_move_assignable_v<T1> && is_nothrow_move_assignable_v<T2>

24  Returns: *this.

template<class U1, class U2> pair& operator=(pair<U1, U2>&& p);

25  Effects: Assigns to first with std::forward<U>(p.first) and to second with std::forward<V>(p.second).

26  Remarks: This operator shall not participate in overload resolution unless is assignable_v<first_type&, U1&&> is true and is assignable_v<second_type&, U2&&> is true.

27  Returns: *this.

void swap(pair& p) noexcept(see below);

28  Requires: first shall be swappable with (??) p.first and second shall be swappable with p.second.

29  Effects: Swaps first with p.first and second with p.second.

30  Remarks: The expression inside noexcept is equivalent to:
    is_nothrow_swappable_v<first_type> && is_nothrow_swappable_v<second_type>

```

### 23.4.3 Specialized algorithms

[pairs.spec]

```

template<class T1, class T2>
constexpr bool operator==(const pair<T1, T2>& x, const pair<T1, T2>& y);

1   Returns: x.first == y.first && x.second == y.second.

template<class T1, class T2>
constexpr bool operator<(const pair<T1, T2>& x, const pair<T1, T2>& y);

2   Returns: x.first < y.first || (!(y.first < x.first) && x.second < y.second).

template<class T1, class T2>
constexpr bool operator!=(const pair<T1, T2>& x, const pair<T1, T2>& y);

3   Returns: !(x == y).

template<class T1, class T2>
constexpr bool operator>(const pair<T1, T2>& x, const pair<T1, T2>& y);

4   Returns: y < x.

template<class T1, class T2>
constexpr bool operator>=(const pair<T1, T2>& x, const pair<T1, T2>& y);

5   Returns: !(x < y).

template<class T1, class T2>
constexpr bool operator<=(const pair<T1, T2>& x, const pair<T1, T2>& y);

6   Returns: !(y < x).

template<class T1, class T2> void swap(pair<T1, T2>& x, pair<T1, T2>& y)
    noexcept(noexcept(x.swap(y)));

7   Effects: As if by x.swap(y).

8   Remarks: This function shall not participate in overload resolution unless is_swappable_v<T1> is true and is_swappable_v<T2> is true.

template<class T1, class T2>
constexpr pair<V1, V2> make_pair(T1&& x, T2&& y);

9   Returns: pair<V1, V2>(std::forward<T1>(x), std::forward<T2>(y)), where V1 and V2 are determined as follows: Let Ui be decay_t<Ti> for each Ti. If Ui is a specialization of reference_wrapper, then Vi is Ui::type&, otherwise Vi is Ui.
```

10 [Example: In place of:

```
return pair<int, double>(5, 3.1415926); // explicit types
```

a C++ program may contain:

```
return make_pair(5, 3.1415926); // types are deduced
```

— end example]

### 23.4.4 Tuple-like access to pair

[pair.astuple]

```

template<class T1, class T2>
struct tuple_size<pair<T1, T2>> : integral_constant<size_t, 2> { };

```

```

tuple_element<I, pair<T1, T2>>::type

1   Requires: I < 2. The program is ill-formed if I is out of bounds.

2   Value: The type T1 if I == 0, otherwise the type T2.

template<size_t I, class T1, class T2>
    constexpr tuple_element_t<I, pair<T1, T2>>& get(pair<T1, T2>& p) noexcept;
template<size_t I, class T1, class T2>
    constexpr const tuple_element_t<I, pair<T1, T2>>& get(const pair<T1, T2>& p) noexcept;
template<size_t I, class T1, class T2>
    constexpr tuple_element_t<I, pair<T1, T2>>&& get(pair<T1, T2>&& p) noexcept;
template<size_t I, class T1, class T2>
    constexpr const tuple_element_t<I, pair<T1, T2>>&& get(const pair<T1, T2>&& p) noexcept;

3   Returns: If I == 0 returns a reference to p.first; if I == 1 returns a reference to p.second; otherwise
        the program is ill-formed.

template<class T1, class T2>
    constexpr T1& get(pair<T1, T2>& p) noexcept;
template<class T1, class T2>
    constexpr const T1& get(const pair<T1, T2>& p) noexcept;
template<class T1, class T2>
    constexpr T1&& get(pair<T1, T2>&& p) noexcept;
template<class T1, class T2>
    constexpr const T1&& get(const pair<T1, T2>&& p) noexcept;

4   Requires: T1 and T2 are distinct types. Otherwise, the program is ill-formed.

5   Returns: A reference to p.first.

template<class T2, class T1>
    constexpr T2& get(pair<T1, T2>& p) noexcept;
template<class T2, class T1>
    constexpr const T2& get(const pair<T1, T2>& p) noexcept;
template<class T2, class T1>
    constexpr T2&& get(pair<T1, T2>&& p) noexcept;
template<class T2, class T1>
    constexpr const T2&& get(const pair<T1, T2>&& p) noexcept;

6   Requires: T1 and T2 are distinct types. Otherwise, the program is ill-formed.

7   Returns: A reference to p.second.

```

### 23.4.5 Piecewise construction

[pair.piecewise]

```

struct piecewise_construct_t {
    explicit piecewise_construct_t() = default;
};

inline constexpr piecewise_construct_t piecewise_construct{};

```

<sup>1</sup> The struct `piecewise_construct_t` is an empty structure type used as a unique type to disambiguate constructor and function overloading. Specifically, `pair` has a constructor with `piecewise_construct_t` as the first argument, immediately followed by two `tuple` (??) arguments used for piecewise construction of the elements of the `pair` object.

## 23.5 Tuples

[tuple]

### 23.5.1 In general

[tuple.general]

- <sup>1</sup> This subclause describes the tuple library that provides a tuple type as the class template `tuple` that can be instantiated with any number of arguments. Each template argument specifies the type of an element in the `tuple`. Consequently, tuples are heterogeneous, fixed-size collections of values. An instantiation of `tuple` with two arguments is similar to an instantiation of `pair` with the same two arguments. See ??.

### 23.5.2 Header <tuple> synopsis

[tuple.syn]

```
namespace std {
    // ??, class template tuple
    template<class... Types>
        class tuple;

    // ??, tuple creation functions
    inline constexpr unspecified ignore;

    template<class... TTypes>
        constexpr tuple<VTypes...> make_tuple(TTypes&&...);

    template<class... TTypes>
        constexpr tuple<TTypes&&...> forward_as_tuple(TTypes&&...) noexcept;

    template<class... TTypes>
        constexpr tuple<TTypes&&...> tie(TTypes&...) noexcept;

    template<class... Tuples>
        constexpr tuple<CTypes...> tuple_cat(Tuples&&...);

    // ??, calling a function with a tuple of arguments
    template<class F, class Tuple>
        constexpr decltype(auto) apply(F&& f, Tuple&& t);

    template<class T, class Tuple>
        constexpr T make_from_tuple(Tuple&& t);

    // ??, tuple helper classes
    template<class T> class tuple_size;                                // not defined

template<class Alloc, class... UTypes>
tuple(allocator_arg_t, Alloc, tuple<UTypes...>) -> tuple<UTypes...>;
}

```

### 23.5.3.1 Construction

[tuple.cnstr]

- <sup>1</sup> For each `tuple` constructor, an exception is thrown only if the construction of one of the types in `Types` throws an exception.
- <sup>2</sup> The defaulted move and copy constructor, respectively, of `tuple` shall be a `constexpr` function if and only if all required element-wise initializations for copy and move, respectively, would satisfy the requirements for a `constexpr` function. The defaulted move and copy constructor of `tuple<>` shall be `constexpr` functions.
- <sup>3</sup> The destructor of `tuple` shall be a trivial destructor if `(is_trivially_destructible_v<Types> && ...)` is `true`.
- <sup>4</sup> In the constructor descriptions that follow, let  $i$  be in the range `[0, sizeof...(Types))` in order,  $T_i$  be the  $i^{\text{th}}$  type in `Types`, and  $U_i$  be the  $i^{\text{th}}$  type in a template parameter pack named `UTypes`, where indexing is zero-based.

*EXPLICIT constexpr tuple();*

- <sup>5</sup> *Effects:* Value-initializes each element.

- <sup>6</sup> *Remarks:* This constructor shall not participate in overload resolution unless `is_default_constructible_v<Ti>` is `true` for all  $i$ . [ *Note:* This behavior can be implemented by a constructor template with default template arguments. — *end note* ] The constructor is explicit if and only if  $T_i$  is not implicitly default-constructible for at least one  $i$ . [ *Note:* This behavior can be implemented with a trait that checks whether a `const Ti&` can be initialized with `{}`. — *end note* ]

```
EXPLICIT constexpr tuple(const Types&...);
```

7     *Effects:* Initializes each element with the value of the corresponding parameter.

8     *Remarks:* This constructor shall not participate in overload resolution unless `sizeof...(Types) >= 1` and `is_copy_constructible_v<Ti>` is `true` for all  $i$ . The constructor is explicit if and only if `is_convertible_v<const Ti&, Ti>` is `false` for at least one  $i$ .

```
template<class... UTypes> EXPLICIT constexpr tuple(UTypes&&... u);
```

9     *Effects:* Initializes the elements in the tuple with the corresponding value in `std::forward<UTypes>(u)`.

10    *Remarks:* This constructor shall not participate in overload resolution unless `sizeof...(Types) == sizeof...(UTypes)` and `sizeof...(Types) >= 1` and `is_constructible_v<Ui, Ui&&>` is `true` for all  $i$ . The constructor is explicit if and only if `is_convertible_v<Ui&&, Ti>` is `false` for at least one  $i$ .

```
tuple(const tuple& u) = default;
```

11    *Requires:* `is_copy_constructible_v<Ti>` is `true` for all  $i$ .

12    *Effects:* Initializes each element of `*this` with the corresponding element of `u`.

```
tuple(tuple&& u) = default;
```

13    *Requires:* `is_move_constructible_v<Ti>` is `true` for all  $i$ .

14    *Effects:* For all  $i$ , initializes the  $i^{\text{th}}$  element of `*this` with `std::forward<Ti>(get<i>(u))`.

```
template<class... UTypes> EXPLICIT constexpr tuple(const tuple<UTypes...>& u);
```

15    *Effects:* Initializes each element of `*this` with the corresponding element of `u`.

16    *Remarks:* This constructor shall not participate in overload resolution unless

(16.1) — `sizeof...(Types) == sizeof...(UTypes)` and

(16.2) — `is_constructible_v<Ui, const Ui&&>` is `true` for all  $i$ , and

(16.3) — either `sizeof...(Types) != 1`, or (when `Types...` expands to `T` and `UTypes...` expands to `U`) `is_convertible_v<const tuple<U>&, Ti>`, `is_constructible_v<T, const tuple<U>&>`, and `is_same_v<T, U>` are all `false`.

The constructor is explicit if and only if `is_convertible_v<const Ui&, Ti>` is `false` for at least one  $i$ .

```
template<class... UTypes> EXPLICIT constexpr tuple(tuple<UTypes...>&& u);
```

17    *Effects:* For all  $i$ , initializes the  $i^{\text{th}}$  element of `*this` with `std::forward<Ui>(get<i>(u))`.

18    *Remarks:* This constructor shall not participate in overload resolution unless

(18.1) — `sizeof...(Types) == sizeof...(UTypes)`, and

(18.2) — `is_constructible_v<Ui, Ui&&>` is `true` for all  $i$ , and

(18.3) — either `sizeof...(Types) != 1`, or (when `Types...` expands to `T` and `UTypes...` expands to `U`) `is_convertible_v<tuple<U>, Ti>`, `is_constructible_v<T, tuple<U>>`, and `is_same_v<T, U>` are all `false`.

The constructor is explicit if and only if `is_convertible_v<Ui&&, Ti>` is `false` for at least one  $i$ .

```
template<class U1, class U2> EXPLICIT constexpr tuple(const pair<U1, U2>& u);
```

19    *Effects:* Initializes the first element with `u.first` and the second element with `u.second`.

20     *Remarks:* This constructor shall not participate in overload resolution unless `sizeof...(Types) == 2`,  
       `is_constructible_v<T0, const U1&>` is true and `is_constructible_v<T1, const U2&>` is true.

21     The constructor is explicit if and only if `is_convertible_v<const U1&, T0>` is false or `is_convertible_v<const U2&, T1>` is false.

```
template<class U1, class U2> EXPLICIT constexpr tuple(pair<U1, U2>&& u);
```

22     *Effects:* Initializes the first element with `std::forward<U1>(u.first)` and the second element with  
       `std::forward<U2>(u.second)`.

23     *Remarks:* This constructor shall not participate in overload resolution unless `sizeof...(Types) == 2`,  
       `is_constructible_v<T0, U1&&>` is true and `is_constructible_v<T1, U2&&>` is true.

24     The constructor is explicit if and only if `is_convertible_v<U1&&, T0>` is false or `is_convertible_v<U2&&, T1>` is false.

```
template<class Alloc>
tuple(allocator_arg_t, const Alloc& a);
template<class Alloc>
EXPLICIT tuple(allocator_arg_t, const Alloc& a, const Types&...);
template<class Alloc, class... UTypes>
EXPLICIT tuple(allocator_arg_t, const Alloc& a, UTypes&...);
template<class Alloc>
tuple(allocator_arg_t, const Alloc& a, const tuple&);
template<class Alloc>
tuple(allocator_arg_t, const Alloc& a, tuple&&);
template<class Alloc, class... UTypes>
EXPLICIT tuple(allocator_arg_t, const Alloc& a, const tuple<UTypes...>&);
template<class Alloc, class... UTypes>
EXPLICIT tuple(allocator_arg_t, const Alloc& a, tuple<UTypes...>&&);

template<class Alloc, class U1, class U2>
EXPLICIT tuple(allocator_arg_t, const Alloc& a, const pair<U1, U2>&);

template<class Alloc, class U1, class U2>
EXPLICIT tuple(allocator_arg_t, const Alloc& a, pair<U1, U2>&&);
```

25     *Requires:* Alloc shall meet the requirements for an Allocator (??).

26     *Effects:* Equivalent to the preceding constructors except that each element is constructed with uses-  
       allocator construction (??).

### 23.5.3.2 Assignment

[tuple.assign]

- <sup>1</sup> For each tuple assignment operator, an exception is thrown only if the assignment of one of the types in Types throws an exception. In the function descriptions that follow, let *i* be in the range [0, `sizeof...(Types)`] in order,  $T_i$  be the *i*<sup>th</sup> type in Types, and  $U_i$  be the *i*<sup>th</sup> type in a template parameter pack named UTypes, where indexing is zero-based.

```
tuple& operator=(const tuple& u);
```

- <sup>2</sup> *Effects:* Assigns each element of u to the corresponding element of \*this.

- <sup>3</sup> *Remarks:* This operator shall be defined as deleted unless `is_copy_assignable_v<Ti>` is true for all *i*.

- <sup>4</sup> *Returns:* \*this.

```

tuple& operator=(tuple&& u) noexcept(see below);

5   Effects: For all  $i$ , assigns std::forward<T $_ii$ >(u)) to get< $i$ >(*this).
6   Remarks: This operator shall not participate in overload resolution unless is_moveAssignable_v<T $_i$ >
   is true for all  $i$ .
7   Remarks: The expression inside noexcept is equivalent to the logical AND of the following expressions:
      is_nothrow_moveAssignable_v<T $_i$ >
   where  $T_i$  is the  $i^{\text{th}}$  type in Types.
8   Returns: *this.

template<class... UTypes> tuple& operator=(const tuple<UTypes...>& u);

9   Effects: Assigns each element of  $u$  to the corresponding element of *this.
10  Remarks: This operator shall not participate in overload resolution unless sizeof...(Types) ==
   sizeof...(UTypes) and isAssignable_v<T $_i$ &, const U $_i$ &> is true for all  $i$ .
11  Returns: *this.

template<class... UTypes> tuple& operator=(tuple<UTypes...>&& u);

12  Effects: For all  $i$ , assigns std::forward<U $_ii$ >(u)) to get< $i$ >(*this).
13  Remarks: This operator shall not participate in overload resolution unless isAssignable_v<T $_i$ &,
   U $_i$ &&> == true for all  $i$  and sizeof...(Types) == sizeof...(UTypes).
14  Returns: *this.

template<class U1, class U2> tuple& operator=(const pair<U1, U2>& u);

15  Effects: Assigns  $u.\text{first}$  to the first element of *this and  $u.\text{second}$  to the second element of *this.
16  Remarks: This operator shall not participate in overload resolution unless sizeof...(Types) == 2 and
   isAssignable_v<T $_0$ &, const U $_1$ &> is true for the first type  $T_0$  in Types and isAssignable_v<T $_1$ &,
   const U $_2$ &> is true for the second type  $T_1$  in Types.
17  Returns: *this.

template<class U1, class U2> tuple& operator=(pair<U1, U2>&& u);

18  Effects: Assigns std::forward<U1>(u.\text{first}) to the first element of *this and
   std::forward<U2>(u.\text{second}) to the second element of *this.
19  Remarks: This operator shall not participate in overload resolution unless sizeof...(Types) == 2
   and isAssignable_v<T $_0$ &, U $_1$ &&> is true for the first type  $T_0$  in Types and isAssignable_v<T $_1$ &,
   U $_2$ &&> is true for the second type  $T_1$  in Types.
20  Returns: *this.

```

### 23.5.3.3 swap

[tuple.swap]

```

void swap(tuple& rhs) noexcept(see below);

1  Requires: Each element in *this shall be swappable with (???) the corresponding element in rhs.
2  Effects: Calls swap for each element in *this and its corresponding element in rhs.
3  Remarks: The expression inside noexcept is equivalent to the logical AND of the following expressions:
      is_nothrow_swappable_v<T $_i$ >

```

where  $T_i$  is the  $i^{\text{th}}$  type in `Types`.

4     *Throws:* Nothing unless one of the element-wise `swap` calls throws an exception.

### 23.5.3.4 Tuple creation functions

[`tuple.creation`]

1 In the function descriptions that follow, the members of a parameter pack `XTypes` are denoted by  $X_i$  for  $i$  in `[0, sizeof...(XTypes))` in order, where indexing is zero-based.

```
template<class... TTypes>
constexpr tuple<VTypes...> make_tuple(TTypes&&... t);
```

2 The pack `VTypes` is defined as follows. Let  $U_i$  be `decay_t<Ti>` for each  $T_i$  in `TTypes`. If  $U_i$  is a specialization of `reference_wrapper`, then  $V_i$  in `VTypes` is  $U_i::\text{type}\&$ , otherwise  $V_i$  is  $U_i$ .

3 *Returns:* `tuple<VTypes...>(std::forward<TTypes>(t)...)`.

4 [*Example:*

```
int i; float j;
make_tuple(1, ref(i), cref(j))
```

creates a tuple of type `tuple<int, int&, const float&>`. —end example]

```
template<class... TTypes>
constexpr tuple<TTypes&&...> forward_as_tuple(TTypes&&... t) noexcept;
```

5 *Effects:* Constructs a tuple of references to the arguments in `t` suitable for forwarding as arguments to a function. Because the result may contain references to temporary variables, a program shall ensure that the return value of this function does not outlive any of its arguments (e.g., the program should typically not store the result in a named variable).

6 *Returns:* `tuple<TTypes&&...>(std::forward<TTypes>(t)...)`.

```
template<class... TTypes>
constexpr tuple<TTypes&&...> tie(TTypes&... t) noexcept;
```

7 *Returns:* `tuple<TTypes&...>(t...)`. When an argument in `t` is `ignore`, assigning any value to the corresponding tuple element has no effect.

8 [*Example:* `tie` functions allow one to create tuples that unpack tuples into variables. `ignore` can be used for elements that are not needed:

```
int i; std::string s;
tie(i, ignore, s) = make_tuple(42, 3.14, "C++");
// i == 42, s == "C++"
```

—end example]

```
template<class... Tuples>
constexpr tuple<CTypes...> tuple_cat(Tuples&&... tpls);
```

9 In the following paragraphs, let  $T_i$  be the  $i^{\text{th}}$  type in `Tuples`,  $U_i$  be `remove_reference_t<Ti>`, and  $\text{tp}_i$  be the  $i^{\text{th}}$  parameter in the function parameter pack `tpls`, where all indexing is zero-based.

10 *Requires:* For all  $i$ ,  $U_i$  shall be the type `cvi tuple<Argsi...>`, where  $cv_i$  is the (possibly empty)  $i^{\text{th}}$  `cv-qualifier-seq` and `Argsi` is the parameter pack representing the element types in  $U_i$ . Let  $A_{ik}$  be the  $k^{\text{th}}$  type in `Argsi`. For all  $A_{ik}$  the following requirements shall be satisfied:

(10.1)     — If  $T_i$  is deduced as an lvalue reference type, then `is_constructible_v<Aik, cvi Aik&> == true`, otherwise

(10.2) — `is_constructible_v<Aik, cvi Aik&&> == true.`

11 *Remarks:* The types in `CTypes` shall be equal to the ordered sequence of the extended types `Args0..., Args1..., ..., Argsn-1...`, where *n* is equal to `sizeof...(Tuples)`. Let `ei...` be the *i*<sup>th</sup> ordered sequence of tuple elements of the resulting `tuple` object corresponding to the type sequence `Argsi`.

12 *Returns:* A `tuple` object constructed by initializing the *k<sub>i</sub>*<sup>th</sup> type element `eik` in `ei...` with

```
get<ki>(std::forward<Ti>(tpi))
```

for each valid *k<sub>i</sub>* and each group `ei` in order.

13 [ *Note:* An implementation may support additional types in the parameter pack `Tuples` that support the `tuple`-like protocol, such as `pair` and `array`. — *end note* ]

### 23.5.3.5 Calling a function with a tuple of arguments

[`tuple.apply`]

```
template<class F, class Tuple>
constexpr decltype(auto) apply(F&& f, Tuple&& t);
```

1 *Effects:* Given the exposition-only function:

```
template<class F, class Tuple, size_t... I>
constexpr decltype(auto)
apply_impl(F&& f, Tuple&& t, index_sequence<I...>) { // exposition only
    return(INVOKE(std::forward<F>(f), std::get<I>(std::forward<Tuple>(t))...); // see ??
}
```

Equivalent to:

```
return apply_impl(std::forward<F>(f), std::forward<Tuple>(t),
                  make_index_sequence<tuple_size_v<remove_reference_t<Tuple>>>{});
```

```
template<class T, class Tuple>
constexpr T make_from_tuple(Tuple&& t);
```

2 *Effects:* Given the exposition-only function:

```
template<class T, class Tuple, size_t... I>
constexpr T make_from_tuple_impl(Tuple&& t, index_sequence<I...>) { // exposition only
    return T(get<I>(std::forward<Tuple>(t))...);
}
```

Equivalent to:

```
return make_from_tuple_impl<T>(
    forward<Tuple>(t),
    make_index_sequence<tuple_size_v<remove_reference_t<Tuple>>>{});
```

[ *Note:* The type of `T` must be supplied as an explicit template parameter, as it cannot be deduced from the argument list. — *end note* ]

### 23.5.3.6 Tuple helper classes

[`tuple.helper`]

```
template<class T> struct tuple_size;
```

1 *Remarks:* All specializations of `tuple_size` shall meet the `UnaryTypeTrait` requirements (??) with a base characteristic of `integral_constant<size_t, N>` for some *N*.

```
template<class... Types>
class tuple_size<tuple<Types...>> : public integral_constant<size_t, sizeof...(Types)> { };
```

```
template<size_t I, class... Types>
class tuple_element<I, tuple<Types...>> {
public:
    using type = TI;
};
```

2     *Requires:* `I < sizeof...(Types)`. The program is ill-formed if `I` is out of bounds.

3     *Type:* `TI` is the type of the `I`th element of `Types`, where indexing is zero-based.

```
template<class T> class tuple_size<const T>;
template<class T> class tuple_size<volatile T>;
template<class T> class tuple_size<const volatile T>;
```

4     Let `TS` denote `tuple_size<T>` of the *cv*-unqualified type `T`. If the expression `TS::value` is well-formed when treated as an unevaluated operand, then each of the three templates shall meet the `UnaryTypeTrait` requirements (??) with a base characteristic of

```
integral_constant<size_t, TS::value>
```

Otherwise, they shall have no member `value`.

5     Access checking is performed as if in a context unrelated to `TS` and `T`. Only the validity of the immediate context of the expression is considered. [ *Note:* The compilation of the expression can result in side effects such as the instantiation of class template specializations and function template specializations, the generation of implicitly-defined functions, and so on. Such side effects are not in the “immediate context” and can result in the program being ill-formed. — *end note* ]

6     In addition to being available via inclusion of the `<tuple>` header, the three templates are available when either of the headers `<array>` or `<utility>` are included.

```
template<size_t I, class T> class tuple_element<I, const T>;
template<size_t I, class T> class tuple_element<I, volatile T>;
template<size_t I, class T> class tuple_element<I, const volatile T>;
```

7     Let `TE` denote `tuple_element_t<I, T>` of the *cv*-unqualified type `T`. Then each of the three templates shall meet the `TransformationTrait` requirements (??) with a member `typedef type` that names the following type:

- (7.1)     — for the first specialization, `add_const_t<TE>`,
- (7.2)     — for the second specialization, `add_volatile_t<TE>`, and
- (7.3)     — for the third specialization, `add_cv_t<TE>`.

8     In addition to being available via inclusion of the `<tuple>` header, the three templates are available when either of the headers `<array>` or `<utility>` are included.

### 23.5.3.7 Element access

[`tuple.elem`]

```
template<size_t I, class... Types>
constexpr tuple_element_t<I, tuple<Types...>>&
get(tuple<Types...>& t) noexcept;
template<size_t I, class... Types>
constexpr tuple_element_t<I, tuple<Types...>>&&
get(tuple<Types...>&& t) noexcept; // Note A
```

```

template<size_t I, class... Types>
constexpr const tuple_element_t<I, tuple<Types...>>&
    get(const tuple<Types...>& t) noexcept; // Note B
template<size_t I, class... Types>
constexpr const tuple_element_t<I, tuple<Types...>>&& get(const tuple<Types...>&& t) noexcept;

1   Requires: I < sizeof...(Types). The program is ill-formed if I is out of bounds.

2   Returns: A reference to the Ith element of t, where indexing is zero-based.

3   [ Note A: If a T in Types is some reference type X&, the return type is X&, not X&&. However, if the
   element type is a non-reference type T, the return type is T&&. — end note ]

4   [ Note B: Constness is shallow. If a T in Types is some reference type X&, the return type is X&, not
   const X&. However, if the element type is a non-reference type T, the return type is const T&. This is
   consistent with how constness is defined to work for member variables of reference type. — end note ]

```

```

template<class T, class... Types>
constexpr T& get(tuple<Types...>& t) noexcept;
template<class T, class... Types>
constexpr T&& get(tuple<Types...>&& t) noexcept;
template<class T, class... Types>
constexpr const T& get(const tuple<Types...>& t) noexcept;
template<class T, class... Types>
constexpr const T&& get(const tuple<Types...>&& t) noexcept;

5   Requires: The type T occurs exactly once in Types.... Otherwise, the program is ill-formed.

6   Returns: A reference to the element of t corresponding to the type T in Types.....

7   [ Example:
        const tuple<int, const int, double, double> t(1, 2, 3.4, 5.6);
        const int& i1 = get<int>(t);           // OK. Not ambiguous. i1 == 1
        const int& i2 = get<const int>(t); // OK. Not ambiguous. i2 == 2
        const double& d = get<double>(t); // ERROR. ill-formed
      — end example ]

```

8 [ Note: The reason `get` is a non-member function is that if this functionality had been provided as a member function, code where the type depended on a template parameter would have required using the `template` keyword. — end note ]

### 23.5.3.8 Relational operators

[tuple.rel]

```

template<class... TTypes, class... UTypes>
constexpr bool operator==(const tuple<TTypes...>& t, const tuple<UTypes...>& u);

1   Requires: For all i, where 0 <= i and i < sizeof...(TTypes), get<i>(t) == get<i>(u) is a valid
   expression returning a type that is convertible to bool. sizeof...(TTypes) == sizeof...(UTypes).

2   Returns: true if get<i>(t) == get<i>(u) for all i, otherwise false. For any two zero-length tuples
   e and f, e == f returns true.

3   Effects: The elementary comparisons are performed in order from the zeroth index upwards. No
   comparisons or element accesses are performed after the first equality comparison that evaluates to
   false.

```

```
template<class... TTypes, class... UTypes>
constexpr bool operator<(const tuple<TTypes...>& t, const tuple<UTypes...>& u);
```

4     *Requires:* For all  $i$ , where  $0 \leq i < \text{sizeof...}(TTypes)$ , both  $\text{get} < i > (t) < \text{get} < i > (u)$  and  $\text{get} < i > (u) < \text{get} < i > (t)$  are valid expressions returning types that are convertible to `bool`.  $\text{sizeof...}(TTypes) == \text{sizeof...}(UTypes)$ .

5     *Returns:* The result of a lexicographical comparison between  $t$  and  $u$ . The result is defined as:  $(\text{bool})(\text{get} < 0 > (t) < \text{get} < 0 > (u)) \mid\mid (\text{!}(\text{bool})(\text{get} < 0 > (u) < \text{get} < 0 > (t)) \&\& t_{\text{tail}} < u_{\text{tail}})$ , where  $r_{\text{tail}}$  for some tuple  $r$  is a tuple containing all but the first element of  $r$ . For any two zero-length tuples  $e$  and  $f$ ,  $e < f$  returns `false`.

```
template<class... TTypes, class... UTypes>
constexpr bool operator!= (const tuple<TTypes...>& t, const tuple<UTypes...>& u);
```

6     *Returns:*  $!(t == u)$ .

```
template<class... TTypes, class... UTypes>
constexpr bool operator> (const tuple<TTypes...>& t, const tuple<UTypes...>& u);
```

7     *Returns:*  $u < t$ .

```
template<class... TTypes, class... UTypes>
constexpr bool operator<= (const tuple<TTypes...>& t, const tuple<UTypes...>& u);
```

8     *Returns:*  $!(u < t)$ .

```
template<class... TTypes, class... UTypes>
constexpr bool operator>= (const tuple<TTypes...>& t, const tuple<UTypes...>& u);
```

9     *Returns:*  $!(t < u)$ .

10 [ *Note:* The above definitions for comparison functions do not require  $t_{\text{tail}}$  (or  $u_{\text{tail}}$ ) to be constructed. It may not even be possible, as  $t$  and  $u$  are not required to be copy constructible. Also, all comparison functions are short circuited; they do not perform element accesses beyond what is required to determine the result of the comparison. — *end note* ]

### 23.5.3.9 Tuple traits

[tuple.traits]

```
template<class... Types, class Alloc>
struct uses_allocator<tuple<Types...>, Alloc> : true_type { };
```

1     *Requires:* `Alloc` shall be an `Allocator` (??).

2     [ *Note:* Specialization of this trait informs other library components that `tuple` can be constructed with an allocator, even though it does not have a nested `allocator_type`. — *end note* ]

### 23.5.3.10 Tuple specialized algorithms

[tuple.special]

```
template<class... Types>
void swap(tuple<Types...>& x, tuple<Types...>& y) noexcept(see below);
```

1     *Remarks:* This function shall not participate in overload resolution unless `is_swappable_v<Ti>` is `true` for all  $i$ , where  $0 \leq i < \text{sizeof...}(Types)$ . The expression inside `noexcept` is equivalent to:

```
    noexcept(x.swap(y))
```

2     *Effects:* As if by `x.swap(y)`.

## 23.6 Optional objects

[optional]

### 23.6.1 In general

[optional.general]

- <sup>1</sup> This subclause describes class template `optional` that represents optional objects. An *optional object* is an object that contains the storage for another object and manages the lifetime of this contained object, if any. The contained object may be initialized after the optional object has been initialized, and may be destroyed before the optional object has been destroyed. The initialization state of the contained object is tracked by the optional object.

### 23.6.2 Header <optional> synopsis

[optional.syn]

```
namespace std {
    // ??, class template optional
    template<class T>
    class optional;

    // ??, no-value state indicator
    struct nullopt_t{see below};
    inline constexpr nullopt_t nullopt(unspecified);

    // ??, class bad_optional_access
    class bad_optional_access;

    // ??, relational operators
    template<class T, class U>
    constexpr bool operator==(const optional<T>&, const optional<U>&);
    template<class T, class U>
    constexpr bool operator!=(const optional<T>&, const optional<U>&);
    template<class T, class U>
    constexpr bool operator<(const optional<T>&, const optional<U>&);
    template<class T, class U>
    constexpr bool operator>(const optional<T>&, const optional<U>&);
    template<class T, class U>
    constexpr bool operator<=(const optional<T>&, const optional<U>&);
    template<class T, class U>
    constexpr bool operator>=(const optional<T>&, const optional<U>&);

    // ??, comparison with nullopt
    template<class T> constexpr bool operator==(const optional<T>&, nullopt_t) noexcept;
    template<class T> constexpr bool operator==(nullopt_t, const optional<T>&) noexcept;
    template<class T> constexpr bool operator!=(const optional<T>&, nullopt_t) noexcept;
    template<class T> constexpr bool operator!=(nullopt_t, const optional<T>&) noexcept;
    template<class T> constexpr bool operator<(const optional<T>&, nullopt_t) noexcept;
    template<class T> constexpr bool operator<(nullopt_t, const optional<T>&) noexcept;
    template<class T> constexpr bool operator<=(const optional<T>&, nullopt_t) noexcept;
    template<class T> constexpr bool operator<=(nullopt_t, const optional<T>&) noexcept;
    template<class T> constexpr bool operator>(const optional<T>&, nullopt_t) noexcept;
    template<class T> constexpr bool operator>(nullopt_t, const optional<T>&) noexcept;
    template<class T> constexpr bool operator>=(const optional<T>&, nullopt_t) noexcept;
    template<class T> constexpr bool operator>=(nullopt_t, const optional<T>&) noexcept;
```

```

// ??, comparison with T
template<class T, class U> constexpr bool operator==(const optional<T>&, const U&);
template<class T, class U> constexpr bool operator==(const T&, const optional<U>&);
template<class T, class U> constexpr bool operator!=(const optional<T>&, const U&);
template<class T, class U> constexpr bool operator!=(const T&, const optional<U>&);
template<class T, class U> constexpr bool operator<(const optional<T>&, const U&);
template<class T, class U> constexpr bool operator<(const T&, const optional<U>&);
template<class T, class U> constexpr bool operator<=(const optional<T>&, const U&);
template<class T, class U> constexpr bool operator<=(const T&, const optional<U>&);
template<class T, class U> constexpr bool operator>(const optional<T>&, const U&);
template<class T, class U> constexpr bool operator>(const T&, const optional<U>&);
template<class T, class U> constexpr bool operator>=(const optional<T>&, const U&);
template<class T, class U> constexpr bool operator>=(const T&, const optional<U>&);

// ??, specialized algorithms
template<class T>
void swap(optional<T>&, optional<T>&) noexcept(see below);

template<class T>
constexpr optional<see below> make_optional(T&&);

template<class T, class... Args>
constexpr optional<T> make_optional(Args&&... args);

template<class T, class U, class... Args>
constexpr optional<T> make_optional(initializer_list<U> il, Args&&... args);

// ??, hash support
template<class T> struct hash;
template<class T> struct hash<optional<T>>;
}
```

<sup>1</sup> A program that necessitates the instantiation of template `optional` for a reference type, or for possibly cv-qualified types `in_place_t` or `nullopt_t` is ill-formed.

### 23.6.3 Class template `optional`

[`optional.optional`]

```

template<class T>
class optional {
public:
    using value_type = T;

    // ??, constructors
    constexpr optional() noexcept;
    constexpr optional(nullopt_t) noexcept;
    constexpr optional(const optional&);
    constexpr optional(optional&&) noexcept(see below);
    template<class... Args>
        constexpr explicit optional(in_place_t, Args&&...);
    template<class U, class... Args>
        constexpr explicit optional(in_place_t, initializer_list<U>, Args&&...);
    template<class U = T>
        EXPLICIT constexpr optional(U&&);
```

```

template<class U>
EXPLICIT optional(const optional<U>&);

template<class U>
EXPLICIT optional(optional<U>&&);

// ??, destructor
~optional();

// ??, assignment
optional& operator=(nullopt_t) noexcept;
optional& operator=(const optional&);
optional& operator=(optional&&) noexcept(see below);
template<class U = T> optional& operator=(U&&);
template<class U> optional& operator=(const optional<U>&);
template<class U> optional& operator=(optional<U>&&);
template<class... Args> T& emplace(Args&&...);
template<class U, class... Args> T& emplace(initializer_list<U>, Args&&...);

// ??, swap
void swap(optional&) noexcept(see below);

// ??, observers
constexpr const T* operator->() const;
constexpr T* operator->();
constexpr const T& operator*() const&;
constexpr T& operator*() &;
constexpr T&& operator*() &&;
constexpr const T&& operator*() const&&;
constexpr explicit operator bool() const noexcept;
constexpr bool has_value() const noexcept;
constexpr const T& value() const&;
constexpr T& value() &;
constexpr T&& value() &&;
constexpr const T&& value() const&&;
template<class U> constexpr T value_or(U&&) const&;
template<class U> constexpr T value_or(U&&) &&;

// ??, modifiers
void reset() noexcept;

private:
    T *val; // exposition only
};

template<class T> optional(T) -> optional<T>;

```

<sup>1</sup> Any instance of `optional<T>` at any given time either contains a value or does not contain a value. When an instance of `optional<T>` *contains a value*, it means that an object of type `T`, referred to as the optional object's *contained value*, is allocated within the storage of the optional object. Implementations are not permitted to use additional storage, such as dynamic memory, to allocate its contained value. The contained

value shall be allocated in a region of the `optional<T>` storage suitably aligned for the type `T`. When an object of type `optional<T>` is contextually converted to `bool`, the conversion returns `true` if the object contains a value; otherwise the conversion returns `false`.

- 2 Member `val` is provided for exposition only. When an `optional<T>` object contains a value, `val` points to the contained value.
- 3 `T` shall be an object type and shall satisfy the requirements of `Destructible` (Table ??).

### 23.6.3.1 Constructors

[`optional.ctor`]

```
constexpr optional() noexcept;
constexpr optional(nullopt_t) noexcept;
```

1 *Postconditions*: `*this` does not contain a value.

2 *Remarks*: No contained value is initialized. For every object type `T` these constructors shall be `constexpr` constructors (??).

```
constexpr optional(const optional& rhs);
```

3 *Effects*: If `rhs` contains a value, initializes the contained value as if direct-non-list-initializing an object of type `T` with the expression `*rhs`.

4 *Postconditions*: `bool(rhs) == bool(*this)`.

5 *Throws*: Any exception thrown by the selected constructor of `T`.

6 *Remarks*: This constructor shall be defined as deleted unless `is_copy_constructible_v<T>` is `true`. If `is_trivially_copy_constructible_v<T>` is `true`, this constructor shall be a `constexpr` constructor.

```
constexpr optional(optional&& rhs) noexcept(see below);
```

7 *Effects*: If `rhs` contains a value, initializes the contained value as if direct-non-list-initializing an object of type `T` with the expression `std::move(*rhs)`. `bool(rhs)` is unchanged.

8 *Postconditions*: `bool(rhs) == bool(*this)`.

9 *Throws*: Any exception thrown by the selected constructor of `T`.

10 *Remarks*: The expression inside `noexcept` is equivalent to `is_nothrow_move_constructible_v<T>`. This constructor shall not participate in overload resolution unless `is_move_constructible_v<T>` is `true`. If `is_trivially_move_constructible_v<T>` is `true`, this constructor shall be a `constexpr` constructor.

```
template<class... Args> constexpr explicit optional(in_place_t, Args&&... args);
```

11 *Effects*: Initializes the contained value as if direct-non-list-initializing an object of type `T` with the arguments `std::forward<Args>(args)....`

12 *Postconditions*: `*this` contains a value.

13 *Throws*: Any exception thrown by the selected constructor of `T`.

14 *Remarks*: If `T`'s constructor selected for the initialization is a `constexpr` constructor, this constructor shall be a `constexpr` constructor. This constructor shall not participate in overload resolution unless `is_constructible_v<T, Args...>` is `true`.

```

template<class U, class... Args>
constexpr explicit optional(in_place_t, initializer_list<U> il, Args&&... args);

15   Effects: Initializes the contained value as if direct-non-list-initializing an object of type T with the
               arguments il, std::forward<Args>(args)....  

16   Postconditions: *this contains a value.  

17   Throws: Any exception thrown by the selected constructor of T.  

18   Remarks: This constructor shall not participate in overload resolution unless is_constructible_v<T,
              initializer_list<U>&, Args&&...> is true. If T's constructor selected for the initialization is a
              constexpr constructor, this constructor shall be a constexpr constructor.  

19 [ Note: The following constructors are conditionally specified as explicit. This is typically implemented by
  declaring two such constructors, of which at most one participates in overload resolution. — end note ]  

template<class U = T> EXPLICIT constexpr optional(U&& v);  

20   Effects: Initializes the contained value as if direct-non-list-initializing an object of type T with the
               expression std::forward<U>(v).  

21   Postconditions: *this contains a value.  

22   Throws: Any exception thrown by the selected constructor of T.  

23   Remarks: If T's selected constructor is a constexpr constructor, this constructor shall be a constexpr
              constructor. This constructor shall not participate in overload resolution unless is_constructible_v<T,
              U&&> is true, is_same_v<remove_cvref_t<U>, in_place_t> is false, and is_same_v<remove_
              cvref_t<U>, optional> is false. The constructor is explicit if and only if is_convertible_v<U&&,
              T> is false.  

template<class U> EXPLICIT optional(const optional<U>& rhs);  

24   Effects: If rhs contains a value, initializes the contained value as if direct-non-list-initializing an object
               of type T with the expression *rhs.  

25   Postconditions: bool(rhs) == bool(*this).  

26   Throws: Any exception thrown by the selected constructor of T.  

27   Remarks: This constructor shall not participate in overload resolution unless
  

(27.1)   — is_constructible_v<T, const U&> is true,  

(27.2)   — is_constructible_v<T, optional<U>&> is false,  

(27.3)   — is_constructible_v<T, optional<U>&&> is false,  

(27.4)   — is_constructible_v<T, const optional<U>&> is false,  

(27.5)   — is_constructible_v<T, const optional<U>&&> is false,  

(27.6)   — is_convertible_v<optional<U>&, T> is false,  

(27.7)   — is_convertible_v<optional<U>&&, T> is false,  

(27.8)   — is_convertible_v<const optional<U>&, T> is false, and  

(27.9)   — is_convertible_v<const optional<U>&&, T> is false.
```

The constructor is explicit if and only if is\_convertible\_v<const U&, T> is false.

```
template<class U> EXPLICIT optional(optional<U>&& rhs);
```

28     *Effects:* If `rhs` contains a value, initializes the contained value as if direct-non-list-initializing an object of type `T` with the expression `std::move(*rhs)`. `bool(rhs)` is unchanged.

29     *Postconditions:* `bool(rhs) == bool(*this)`.

30     *Throws:* Any exception thrown by the selected constructor of `T`.

31     *Remarks:* This constructor shall not participate in overload resolution unless

- (31.1)     — `is_constructible_v<T, U&&>` is true,
- (31.2)     — `is_constructible_v<T, optional<U>&>` is false,
- (31.3)     — `is_constructible_v<T, optional<U>&&>` is false,
- (31.4)     — `is_constructible_v<T, const optional<U>&>` is false,
- (31.5)     — `is_constructible_v<T, const optional<U>&&>` is false,
- (31.6)     — `is_convertible_v<optional<U>&, T>` is false,
- (31.7)     — `is_convertible_v<optional<U>&&, T>` is false,
- (31.8)     — `is_convertible_v<const optional<U>&, T>` is false, and
- (31.9)     — `is_convertible_v<const optional<U>&&, T>` is false.

The constructor is explicit if and only if `is_convertible_v<U&&, T>` is false.

### 23.6.3.2 Destructor

[`optional.dtor`]

```
~optional();
```

1     *Effects:* If `is_trivially_destructible_v<T> != true` and `*this` contains a value, calls  
`val->T::~T()`

2     *Remarks:* If `is_trivially_destructible_v<T> == true` then this destructor shall be a trivial de-  
strutor.

### 23.6.3.3 Assignment

[`optional.assign`]

```
optional<T>& operator=(nullopt_t) noexcept;
```

1     *Effects:* If `*this` contains a value, calls `val->T::~T()` to destroy the contained value; otherwise no effect.

2     *Returns:* `*this`.

3     *Postconditions:* `*this` does not contain a value.

```
optional<T>& operator=(const optional& rhs);
```

4     *Effects:* See Table ??.

5     *Returns:* `*this`.

6     *Postconditions:* `bool(rhs) == bool(*this)`.

7     *Remarks:* If any exception is thrown, the result of the expression `bool(*this)` remains unchanged. If an exception is thrown during the call to `T`'s copy constructor, no effect. If an exception is thrown during the call to `T`'s copy assignment, the state of its contained value is as defined by the exception safety guarantee of `T`'s copy assignment. This operator shall be defined as deleted unless `is_copy_constructible_v<T>` is true and `is_copy_assignable_v<T>` is true.

Table 35 — `optional::operator=(const optional&)` effects

	<code>*this contains a value</code>	<code>*this does not contain a value</code>
<code>rhs contains a value</code>	assigns <code>*rhs</code> to the contained value	initializes the contained value as if direct-non-list-initializing an object of type <code>T</code> with <code>*rhs</code>
<code>rhs does not contain a value</code>	destroys the contained value by calling <code>val-&gt;T::~T()</code>	no effect

```
optional<T>& operator=(optional&& rhs) noexcept(see below);
```

8     *Effects:* See Table ???. The result of the expression `bool(rhs)` remains unchanged.

Table 36 — `optional::operator=(optional&&)` effects

	<code>*this contains a value</code>	<code>*this does not contain a value</code>
<code>rhs contains a value</code>	assigns <code>std::move(*rhs)</code> to the contained value	initializes the contained value as if direct-non-list-initializing an object of type <code>T</code> with <code>std::move(*rhs)</code>
<code>rhs does not contain a value</code>	destroys the contained value by calling <code>val-&gt;T::~T()</code>	no effect

9     *Returns:* `*this`.

10    *Postconditions:* `bool(rhs) == bool(*this)`.

11    *Remarks:* The expression inside `noexcept` is equivalent to:

```
is_nothrow_move_assignable_v<T> && is_nothrow_move_constructible_v<T>
```

12    If any exception is thrown, the result of the expression `bool(*this)` remains unchanged. If an exception is thrown during the call to `T`'s move constructor, the state of `*rhs.val` is determined by the exception safety guarantee of `T`'s move constructor. If an exception is thrown during the call to `T`'s move assignment, the state of `*val` and `*rhs.val` is determined by the exception safety guarantee of `T`'s move assignment. This operator shall not participate in overload resolution unless `is_move_constructible_v<T>` is true and `is_move_assignable_v<T>` is true.

```
template<class U = T> optional<T>& operator=(U&& v);
```

13    *Effects:* If `*this` contains a value, assigns `std::forward<U>(v)` to the contained value; otherwise initializes the contained value as if direct-non-list-initializing object of type `T` with `std::forward<U>(v)`.

14    *Returns:* `*this`.

15    *Postconditions:* `*this` contains a value.

16    *Remarks:* If any exception is thrown, the result of the expression `bool(*this)` remains unchanged. If an exception is thrown during the call to `T`'s constructor, the state of `v` is determined by the exception safety guarantee of `T`'s constructor. If an exception is thrown during the call to `T`'s assignment, the state of `*val` and `v` is determined by the exception safety guarantee of `T`'s assignment. This function shall not participate in overload resolution unless `is_same_v<remove_cvref_t<U>, optional>` is false, `conjunction_v<is_scalar<T>, is_same<T, decay_t<U>>>` is false, `is_constructible_v<T, U>` is true, and `is_assignable_v<T&, U>` is true.

```
template<class U> optional<T>& operator=(const optional<U>& rhs);
```

17     *Effects:* See Table ??.

Table 37 — optional::operator=(const optional<U>&) effects

	*this contains a value	*this does not contain a value
rhs contains a value	assigns *rhs to the contained value	initializes the contained value as if direct-non-list-initializing an object of type T with *rhs
rhs does not contain a value	destroys the contained value by calling val->T::~T()	no effect

18     *Returns:* \*this.

19     *Postconditions:* bool(rhs) == bool(\*this).

20     *Remarks:* If any exception is thrown, the result of the expression bool(\*this) remains unchanged. If an exception is thrown during the call to T's constructor, the state of \*rhs.val is determined by the exception safety guarantee of T's constructor. If an exception is thrown during the call to T's assignment, the state of \*val and \*rhs.val is determined by the exception safety guarantee of T's assignment. This function shall not participate in overload resolution unless

- (20.1) — `is_constructible_v<T, const U&>` is true,
- (20.2) — `is_assignable_v<T&, const U&>` is true,
- (20.3) — `is_constructible_v<T, optional<U>&>` is false,
- (20.4) — `is_constructible_v<T, optional<U>&&>` is false,
- (20.5) — `is_constructible_v<T, const optional<U>&>` is false,
- (20.6) — `is_constructible_v<T, const optional<U>&&>` is false,
- (20.7) — `is_convertible_v<optional<U>&, T>` is false,
- (20.8) — `is_convertible_v<optional<U>&&, T>` is false,
- (20.9) — `is_convertible_v<const optional<U>&, T>` is false,
- (20.10) — `is_convertible_v<const optional<U>&&, T>` is false,
- (20.11) — `is_assignable_v<T&, optional<U>&>` is false,
- (20.12) — `is_assignable_v<T&, optional<U>&&>` is false,
- (20.13) — `is_assignable_v<T&, const optional<U>&>` is false, and
- (20.14) — `is_assignable_v<T&, const optional<U>&&>` is false.

```
template<class U> optional<T>& operator=(optional<U>&& rhs);
```

21     *Effects:* See Table ??.. The result of the expression bool(rhs) remains unchanged.

22     *Returns:* \*this.

23     *Postconditions:* bool(rhs) == bool(\*this).

24     *Remarks:* If any exception is thrown, the result of the expression bool(\*this) remains unchanged. If an exception is thrown during the call to T's constructor, the state of \*rhs.val is determined by the exception safety guarantee of T's constructor. If an exception is thrown during the call to T's

Table 38 — `optional::operator=(optional<U>&&)` effects

	<code>*this contains a value</code>	<code>*this does not contain a value</code>
<code>rhs contains a value</code>	assigns <code>std::move(*rhs)</code> to the contained value	initializes the contained value as if direct-non-list-initializing an object of type T with <code>std::move(*rhs)</code>
<code>rhs does not contain a value</code>	destroys the contained value by calling <code>val-&gt;T::~T()</code>	no effect

assignment, the state of `*val` and `*rhs.val` is determined by the exception safety guarantee of T's assignment. This function shall not participate in overload resolution unless

- (24.1) — `is_constructible_v<T, U>` is true,
- (24.2) — `is_assignable_v<T&, U>` is true,
- (24.3) — `is_constructible_v<T, optional<U>&>` is false,
- (24.4) — `is_constructible_v<T, optional<U>&&>` is false,
- (24.5) — `is_constructible_v<T, const optional<U>&>` is false,
- (24.6) — `is_constructible_v<T, const optional<U>&&>` is false,
- (24.7) — `is_convertible_v<optional<U>&, T>` is false,
- (24.8) — `is_convertible_v<optional<U>&&, T>` is false,
- (24.9) — `is_convertible_v<const optional<U>&, T>` is false,
- (24.10) — `is_convertible_v<const optional<U>&&, T>` is false,
- (24.11) — `is_assignable_v<T&, optional<U>&>` is false,
- (24.12) — `is_assignable_v<T&, optional<U>&&>` is false,
- (24.13) — `is_assignable_v<T&, const optional<U>&>` is false, and
- (24.14) — `is_assignable_v<T&, const optional<U>&&>` is false.

`template<class... Args> T& emplace(Args&&... args);`

25     *Requires:* `is_constructible_v<T, Args&&...>` is true.

26     *Effects:* Calls `*this = nullopt`. Then initializes the contained value as if direct-non-list-initializing an object of type T with the arguments `std::forward<Args>(args)....`

27     *Postconditions:* `*this` contains a value.

28     *Returns:* A reference to the new contained value.

29     *Throws:* Any exception thrown by the selected constructor of T.

30     *Remarks:* If an exception is thrown during the call to T's constructor, `*this` does not contain a value, and the previous `*val` (if any) has been destroyed.

`template<class U, class... Args> T& emplace(initializer_list<U> il, Args&&... args);`

31     *Effects:* Calls `*this = nullopt`. Then initializes the contained value as if direct-non-list-initializing an object of type T with the arguments `il, std::forward<Args>(args)....`

32     *Postconditions:* `*this` contains a value.

33        *Returns:* A reference to the new contained value.

34        *Throws:* Any exception thrown by the selected constructor of T.

35        *Remarks:* If an exception is thrown during the call to T's constructor, `*this` does not contain a value, and the previous `*val` (if any) has been destroyed. This function shall not participate in overload resolution unless `is_constructible_v<T, initializer_list<U>&, Args&&...>` is true.

### 23.6.3.4 Swap

[`optional.swap`]

```
void swap(optional& rhs) noexcept(see below);
```

1        *Requires:* Lvalues of type T shall be swappable and `is_move_constructible_v<T>` is true.

2        *Effects:* See Table ??.

Table 39 — `optional::swap(optional&)` effects

	<code>*this contains a value</code>	<code>*this does not contain a value</code>
<code>rhs contains a value</code>	calls <code>swap(*(*this), *rhs)</code>	initializes the contained value of <code>*this</code> as if direct-non-list-initializing an object of type T with the expression <code>std::move(*rhs)</code> , followed by <code>rhs.val-&gt;T::~T()</code> ; postcondition is that <code>*this</code> contains a value and <code>rhs</code> does not contain a value
<code>rhs does not contain a value</code>	initializes the contained value of <code>rhs</code> as if direct-non-list-initializing an object of type T with the expression <code>std::move(*(*this))</code> , followed by <code>val-&gt;T::~T()</code> ; postcondition is that <code>*this</code> does not contain a value and <code>rhs</code> contains a value	no effect

3        *Throws:* Any exceptions thrown by the operations in the relevant part of Table ??.

4        *Remarks:* The expression inside `noexcept` is equivalent to:

```
is_nothrow_move_constructible_v<T> && is_nothrow_swappable_v<T>
```

If any exception is thrown, the results of the expressions `bool(*this)` and `bool(rhs)` remain unchanged. If an exception is thrown during the call to function `swap`, the state of `*val` and `*rhs.val` is determined by the exception safety guarantee of `swap` for lvalues of T. If an exception is thrown during the call to T's move constructor, the state of `*val` and `*rhs.val` is determined by the exception safety guarantee of T's move constructor.

### 23.6.3.5 Observers

[`optional.observe`]

```
constexpr const T* operator->() const;
constexpr T* operator->();
```

1        *Requires:* `*this` contains a value.

2        *Returns:* `val`.

3       *Throws:* Nothing.

4       *Remarks:* These functions shall be constexpr functions.

```
constexpr const T& operator*() const&;
constexpr T& operator*() &;
```

5       *Requires:* \*this contains a value.

6       *Returns:* \*val.

7       *Throws:* Nothing.

8       *Remarks:* These functions shall be constexpr functions.

```
constexpr T&& operator*() &&;
constexpr const T&& operator*() const&&;
```

9       *Requires:* \*this contains a value.

10      *Effects:* Equivalent to: return std::move(\*val);

```
constexpr explicit operator bool() const noexcept;
```

11      *Returns:* true if and only if \*this contains a value.

12      *Remarks:* This function shall be a constexpr function.

```
constexpr bool has_value() const noexcept;
```

13      *Returns:* true if and only if \*this contains a value.

14      *Remarks:* This function shall be a constexpr function.

```
constexpr const T& value() const&;
constexpr T& value() &;
```

15      *Effects:* Equivalent to:

```
return bool(*this) ? *val : throw bad_optional_access();
```

```
constexpr T&& value() &&;
constexpr const T&& value() const&&;
```

16      *Effects:* Equivalent to:

```
return bool(*this) ? std::move(*val) : throw bad_optional_access();
```

```
template<class U> constexpr T value_or(U&& v) const&;
```

17      *Effects:* Equivalent to:

```
return bool(*this) ? **this : static_cast<T>(std::forward<U>(v));
```

18      *Remarks:* If is\_copy\_constructible\_v<T> && is\_convertible\_v<U&&, T> is false, the program is ill-formed.

```
template<class U> constexpr T value_or(U&& v) &&;
```

19      *Effects:* Equivalent to:

```
return bool(*this) ? std::move(**this) : static_cast<T>(std::forward<U>(v));
```

20      *Remarks:* If is\_move\_constructible\_v<T> && is\_convertible\_v<U&&, T> is false, the program is ill-formed.

**23.6.3.6 Modifiers**

[optional.mod]

```
void reset() noexcept;
```

<sup>1</sup> *Effects:* If `*this` contains a value, calls `val->T::~T()` to destroy the contained value; otherwise no effect.

<sup>2</sup> *Postconditions:* `*this` does not contain a value.

**23.6.4 No-value state indicator**

[optional.nullopt]

```
struct nullopt_t{see below};  
inline constexpr nullopt_t nullopt(unspecified);
```

<sup>1</sup> The struct `nullopt_t` is an empty structure type used as a unique type to indicate the state of not containing a value for `optional` objects. In particular, `optional<T>` has a constructor with `nullopt_t` as a single argument; this indicates that an optional object not containing a value shall be constructed.

<sup>2</sup> Type `nullopt_t` shall not have a default constructor or an initializer-list constructor, and shall not be an aggregate.

**23.6.5 Class bad\_optional\_access**

[optional.bad.access]

```
class bad_optional_access : public exception {  
public:  
    bad_optional_access();  
};
```

<sup>1</sup> The class `bad_optional_access` defines the type of objects thrown as exceptions to report the situation where an attempt is made to access the value of an optional object that does not contain a value.

```
bad_optional_access();
```

<sup>2</sup> *Effects:* Constructs an object of class `bad_optional_access`.

<sup>3</sup> *Postconditions:* `what()` returns an implementation-defined NTBS.

**23.6.6 Relational operators**

[optional.relops]

```
template<class T, class U> constexpr bool operator==(const optional<T>& x, const optional<U>& y);
```

<sup>1</sup> *Requires:* The expression `*x == *y` shall be well-formed and its result shall be convertible to `bool`.  
[ *Note:* `T` need not be `EqualityComparable`. — *end note* ]

<sup>2</sup> *Returns:* If `bool(x) != bool(y)`, `false`; otherwise if `bool(x) == false`, `true`; otherwise `*x == *y`.

<sup>3</sup> *Remarks:* Specializations of this function template for which `*x == *y` is a core constant expression shall be `constexpr` functions.

```
template<class T, class U> constexpr bool operator!=(const optional<T>& x, const optional<U>& y);
```

<sup>4</sup> *Requires:* The expression `*x != *y` shall be well-formed and its result shall be convertible to `bool`.

<sup>5</sup> *Returns:* If `bool(x) != bool(y)`, `true`; otherwise, if `bool(x) == false`, `false`; otherwise `*x != *y`.

<sup>6</sup> *Remarks:* Specializations of this function template for which `*x != *y` is a core constant expression shall be `constexpr` functions.

```
template<class T, class U> constexpr bool operator<(const optional<T>& x, const optional<U>& y);
```

<sup>7</sup> *Requires:* `*x < *y` shall be well-formed and its result shall be convertible to `bool`.

8       *Returns:* If  $\text{!y}$ , `false`; otherwise, if  $\text{!x}$ , `true`; otherwise  $*x < *y$ .  
 9       *Remarks:* Specializations of this function template for which  $*x < *y$  is a core constant expression  
       shall be `constexpr` functions.

```
template<class T, class U> constexpr bool operator<(const optional<T>& x, const optional<U>& y);
```

10      *Requires:* The expression  $*x > *y$  shall be well-formed and its result shall be convertible to `bool`.

11      *Returns:* If  $\text{!x}$ , `false`; otherwise, if  $\text{!y}$ , `true`; otherwise  $*x > *y$ .

12      *Remarks:* Specializations of this function template for which  $*x > *y$  is a core constant expression  
       shall be `constexpr` functions.

```
template<class T, class U> constexpr bool operator<=(const optional<T>& x, const optional<U>& y);
```

13      *Requires:* The expression  $*x <= *y$  shall be well-formed and its result shall be convertible to `bool`.

14      *Returns:* If  $\text{!x}$ , `true`; otherwise, if  $\text{!y}$ , `false`; otherwise  $*x <= *y$ .

15      *Remarks:* Specializations of this function template for which  $*x <= *y$  is a core constant expression  
       shall be `constexpr` functions.

```
template<class T, class U> constexpr bool operator>=(const optional<T>& x, const optional<U>& y);
```

16      *Requires:* The expression  $*x >= *y$  shall be well-formed and its result shall be convertible to `bool`.

17      *Returns:* If  $\text{!y}$ , `true`; otherwise, if  $\text{!x}$ , `false`; otherwise  $*x >= *y$ .

18      *Remarks:* Specializations of this function template for which  $*x >= *y$  is a core constant expression  
       shall be `constexpr` functions.

### 23.6.7 Comparison with `nullopt` [optional.nullops]

```
template<class T> constexpr bool operator==(const optional<T>& x, nullopt_t) noexcept;
template<class T> constexpr bool operator==(nullopt_t, const optional<T>& x) noexcept;
```

1       *Returns:*  $\text{!x}$ .

```
template<class T> constexpr bool operator!=(const optional<T>& x, nullopt_t) noexcept;
template<class T> constexpr bool operator!=(nullopt_t, const optional<T>& x) noexcept;
```

2       *Returns:* `bool(x)`.

```
template<class T> constexpr bool operator<(const optional<T>& x, nullopt_t) noexcept;
```

3       *Returns:* `false`.

```
template<class T> constexpr bool operator<(nullopt_t, const optional<T>& x) noexcept;
```

4       *Returns:* `bool(x)`.

```
template<class T> constexpr bool operator<=(const optional<T>& x, nullopt_t) noexcept;
```

5       *Returns:*  $\text{!x}$ .

```
template<class T> constexpr bool operator<=(nullopt_t, const optional<T>& x) noexcept;
```

6       *Returns:* `true`.

```
template<class T> constexpr bool operator>=(const optional<T>& x, nullopt_t) noexcept;
```

7       *Returns:* `bool(x)`.

```

template<class T> constexpr bool operator>(nullopt_t, const optional<T>& x) noexcept;
8     Returns: false.

template<class T> constexpr bool operator>=(const optional<T>& x, nullopt_t) noexcept;
9     Returns: true.

template<class T> constexpr bool operator>=(nullopt_t, const optional<T>& x) noexcept;
10    Returns: !x.

```

### 23.6.8 Comparison with T

[optional.comp\_with\_t]

```

template<class T, class U> constexpr bool operator==(const optional<T>& x, const U& v);
1     Requires: The expression *x == v shall be well-formed and its result shall be convertible to bool.  

[ Note: T need not be EqualityComparable. — end note ]
2     Effects: Equivalent to: return bool(x) ? *x == v : false;

template<class T, class U> constexpr bool operator==(const T& v, const optional<U>& x);
3     Requires: The expression v == *x shall be well-formed and its result shall be convertible to bool.
4     Effects: Equivalent to: return bool(x) ? v == *x : false;

template<class T, class U> constexpr bool operator!=(const optional<T>& x, const U& v);
5     Requires: The expression *x != v shall be well-formed and its result shall be convertible to bool.
6     Effects: Equivalent to: return bool(x) ? *x != v : true;

template<class T, class U> constexpr bool operator!=(const T& v, const optional<U>& x);
7     Requires: The expression v != *x shall be well-formed and its result shall be convertible to bool.
8     Effects: Equivalent to: return bool(x) ? v != *x : true;

template<class T, class U> constexpr bool operator<(const optional<T>& x, const U& v);
9     Requires: The expression *x < v shall be well-formed and its result shall be convertible to bool.
10    Effects: Equivalent to: return bool(x) ? *x < v : true;

template<class T, class U> constexpr bool operator<=(const optional<T>& x, const U& v);
11   Requires: The expression v < *x shall be well-formed and its result shall be convertible to bool.
12   Effects: Equivalent to: return bool(x) ? v < *x : false;

template<class T, class U> constexpr bool operator<=(const T& v, const optional<U>& x);
13  Requires: The expression *x <= v shall be well-formed and its result shall be convertible to bool.
14  Effects: Equivalent to: return bool(x) ? *x <= v : true;

template<class T, class U> constexpr bool operator<=(const optional<T>& x, const U& v);
15  Requires: The expression v <= *x shall be well-formed and its result shall be convertible to bool.
16  Effects: Equivalent to: return bool(x) ? v <= *x : false;

template<class T, class U> constexpr bool operator>(const optional<T>& x, const U& v);
17  Requires: The expression *x > v shall be well-formed and its result shall be convertible to bool.

```

```

18   Effects: Equivalent to: return bool(x) ? *x > v : false;
19   template<class T, class U> constexpr bool operator>(const T& v, const optional<U>& x);
20   Requires: The expression v > *x shall be well-formed and its result shall be convertible to bool.
21   Effects: Equivalent to: return bool(x) ? v > *x : true;
22   template<class T, class U> constexpr bool operator>=(const optional<T>& x, const U& v);
23   Requires: The expression *x >= v shall be well-formed and its result shall be convertible to bool.
24   Effects: Equivalent to: return bool(x) ? *x >= v : false;
25   template<class T, class U> constexpr bool operator>=(const T& v, const optional<U>& x);
26   Requires: The expression v >= *x shall be well-formed and its result shall be convertible to bool.
27   Effects: Equivalent to: return bool(x) ? v >= *x : true;

```

### 23.6.9 Specialized algorithms

[optional.specalg]

```

template<class T> void swap(optional<T>& x, optional<T>& y) noexcept(noexcept(x.swap(y)));
1   Effects: Calls x.swap(y).
2   Remarks: This function shall not participate in overload resolution unless is_move_constructible_v<T> is true and is_swappable_v<T> is true.
3   Returns: optional<decay_t<T>>(std::forward<T>(v)).
4   template<class T> constexpr optional<decay_t<T>> make_optional(T&& v);
5   Effects: Equivalent to: return optional<T>(in_place, std::forward<Args>(args)...);
6   template<class T, class... Args>
7   constexpr optional<T> make_optional(Args&&... args);
8   Effects: Equivalent to: return optional<T>(in_place, il, std::forward<Args>(args)...);

```

### 23.6.10 Hash support

[optional.hash]

```
template<class T> struct hash<optional<T>>;
```

1 The specialization `hash<optional<T>>` is enabled (??) if and only if `hash<remove_const_t<T>>` is enabled. When enabled, for an object `o` of type `optional<T>`, if `bool(o) == true`, then `hash<optional<T>>()(o)` shall evaluate to the same value as `hash<remove_const_t<T>>()(o)`; otherwise it evaluates to an unspecified value. The member functions are not guaranteed to be `noexcept`.

## 23.7 Variants

[variant]

### 23.7.1 In general

[variant.general]

1 A variant object holds and manages the lifetime of a value. If the `variant` holds a value, that value's type has to be one of the template argument types given to `variant`. These template arguments are called alternatives.

## 23.7.2 Header &lt;variant&gt; synopsis

[variant.syn]

```

namespace std {

    // ??, class template variant
    template<class... Types>
        class variant;

    // ??, variant helper classes
    template<class T> struct variant_size;                                // not defined
    template<class T> struct variant_size<const T>;
    template<class T> struct variant_size<volatile T>;
    template<class T> struct variant_size<const volatile T>;
    template<class T>
        inline constexpr size_t variant_size_v = variant_size<T>::value;

    template<class... Types>
        struct variant_size<variant<Types...>>;

}
```

### 23.7.3 Class template variant

[variant.variant]

```
namespace std {

    template<class... Types>
    class variant {
        public:
            // ??, constructors
            constexpr variant() noexcept(see below);
            variant(const variant&);
            variant(variant&&) noexcept(see below);

            template<class T>
            constexpr variant(T&&) noexcept(see below);

            template<class T, class... Args>
            constexpr explicit variant(in_place_type_t<T>, Args&&...);
            template<class T, class U, class... Args>
            constexpr explicit variant(in_place_type_t<T>, initializer_list<U>, Args&&...);

            template<size_t I, class... Args>
            constexpr explicit variant(in_place_index_t<I>, Args&&...);
            template<size_t I, class U, class... Args>
            constexpr explicit variant(in_place_index_t<I>, initializer_list<U>, Args&&...);

            // ??, destructor
            ~variant();

            // ??, assignment
            variant& operator=(const variant&);
            variant& operator=(variant&&) noexcept(see below);

            template<class T> variant& operator=(T&&) noexcept(see below);

            // ??, modifiers
            template<class T, class... Args>
            T& emplace(Args&&...);
            template<class T, class U, class... Args>
            T& emplace(initializer_list<U>, Args&&...);
            template<size_t I, class... Args>
            variant_alternative_t<I, variant<Types...>>& emplace(Args&&...);
            template<size_t I, class U, class... Args>
            variant_alternative_t<I, variant<Types...>>& emplace(initializer_list<U>, Args&&...);
    };
}
```

```

// ??, value status
constexpr bool valueless_by_exception() const noexcept;
constexpr size_t index() const noexcept;

// ??, swap
void swap(variant&) noexcept(see below);
};

}

```

- <sup>1</sup> Any instance of **variant** at any given time either holds a value of one of its alternative types, or it holds no value. When an instance of **variant** holds a value of alternative type  $T_i$ , it means that a value of type  $T_i$ , referred to as the **variant** object's *contained value*, is allocated within the storage of the **variant** object. Implementations are not permitted to use additional storage, such as dynamic memory, to allocate the contained value. The contained value shall be allocated in a region of the **variant** storage suitably aligned for all types in **Types**. . . . It is implementation-defined whether over-aligned types are supported.
- <sup>2</sup> All types in **Types**. . . shall be (possibly cv-qualified) object types that are not arrays.
- <sup>3</sup> A program that instantiates the definition of **variant** with no template arguments is ill-formed.

### 23.7.3.1 Constructors

[**variant.ctor**]

- <sup>1</sup> In the descriptions that follow, let  $i$  be in the range  $[0, \text{sizeof...}(\text{Types})]$ , and  $T_i$  be the  $i^{\text{th}}$  type in **Types**. . . .

```
constexpr variant() noexcept(see below);
```

- <sup>2</sup> *Effects:* Constructs a **variant** holding a value-initialized value of type  $T_0$ .
- <sup>3</sup> *Postconditions:* **valueless\_by\_exception()** is **false** and **index()** is 0.
- <sup>4</sup> *Throws:* Any exception thrown by the value-initialization of  $T_0$ .
- <sup>5</sup> *Remarks:* This function shall be **constexpr** if and only if the value-initialization of the alternative type  $T_0$  would satisfy the requirements for a **constexpr** function. The expression inside **noexcept** is equivalent to **is\_nothrow\_default\_constructible\_v<T\_0>**. This function shall not participate in overload resolution unless **is\_default\_constructible\_v<T\_0>** is **true**. [ *Note:* See also class **monostate**. — *end note* ]

```
variant(const variant& w);
```

- <sup>6</sup> *Effects:* If  $w$  holds a value, initializes the **variant** to hold the same alternative as  $w$  and direct-initializes the contained value with **get<j>(w)**, where  $j$  is  $w.\text{index}()$ . Otherwise, initializes the **variant** to not hold a value.

- <sup>7</sup> *Throws:* Any exception thrown by direct-initializing any  $T_i$  for all  $i$ .

- <sup>8</sup> *Remarks:* This constructor shall be defined as deleted unless **is\_copy\_constructible\_v<T\_i>** is **true** for all  $i$ .

```
variant(variant&& w) noexcept(see below);
```

- <sup>9</sup> *Effects:* If  $w$  holds a value, initializes the **variant** to hold the same alternative as  $w$  and direct-initializes the contained value with **get<j>(std::move(w))**, where  $j$  is  $w.\text{index}()$ . Otherwise, initializes the **variant** to not hold a value.

- <sup>10</sup> *Throws:* Any exception thrown by move-constructing any  $T_i$  for all  $i$ .

11     *Remarks:* The expression inside `noexcept` is equivalent to the logical AND of `is_nothrow_move_constructible_v<Ti>` for all  $i$ . This function shall not participate in overload resolution unless `is_move_constructible_v<Ti>` is `true` for all  $i$ .

```
template<class T> constexpr variant(T&& t) noexcept(see below);
```

12     Let  $T_j$  be a type that is determined as follows: build an imaginary function  $FUN(T_i)$  for each alternative type  $T_i$ . The overload  $FUN(T_j)$  selected by overload resolution for the expression  $FUN(\text{std}::\text{forward}\langle T\rangle(t))$  defines the alternative  $T_j$  which is the type of the contained value after construction.

13     *Effects:* Initializes `*this` to hold the alternative type  $T_j$  and direct-initializes the contained value as if direct-non-list-initializing it with `std::forward<T>(t)`.

14     *Postconditions:* `holds_alternative<Tj>(*this)` is `true`.

15     *Throws:* Any exception thrown by the initialization of the selected alternative  $T_j$ .

16     *Remarks:* This function shall not participate in overload resolution unless

(16.1) — `sizeof... (Types)` is nonzero,

(16.2) — `is_same_v<remove_cvref_t<T>, variant>` is `false`,

(16.3) — `remove_cvref_t<T>` is neither a specialization of `in_place_type_t` nor a specialization of `in_place_index_t`,

(16.4) — `is_constructible_v<Tj, T>` is `true`, and

(16.5) — the expression  $FUN(\text{std}::\text{forward}\langle T\rangle(t))$  (with  $FUN$  being the above-mentioned set of imaginary functions) is well-formed.

17     [ *Note:*

```
variant<string, string> v("abc");
```

is ill-formed, as both alternative types have an equally viable constructor for the argument. — *end note* ]

18     The expression inside `noexcept` is equivalent to `is_nothrow_constructible_v<Tj, T>`. If  $T_j$ 's selected constructor is a `constexpr` constructor, this constructor shall be a `constexpr` constructor.

```
template<class T, class... Args> constexpr explicit variant(in_place_type_t<T>, Args&&... args);
```

19     *Effects:* Initializes the contained value as if direct-non-list-initializing an object of type  $T$  with the arguments `std::forward<Args>(args)....`

20     *Postconditions:* `holds_alternative<T>(*this)` is `true`.

21     *Throws:* Any exception thrown by calling the selected constructor of  $T$ .

22     *Remarks:* This function shall not participate in overload resolution unless there is exactly one occurrence of  $T$  in `Types...` and `is_constructible_v<T, Args...>` is `true`. If  $T$ 's selected constructor is a `constexpr` constructor, this constructor shall be a `constexpr` constructor.

```
template<class T, class U, class... Args>
constexpr explicit variant(in_place_type_t<T>, initializer_list<U> il, Args&&... args);
```

23     *Effects:* Initializes the contained value as if direct-non-list-initializing an object of type  $T$  with the arguments `il, std::forward<Args>(args)....`

24     *Postconditions:* `holds_alternative<T>(*this)` is `true`.

25       *Throws:* Any exception thrown by calling the selected constructor of  $T$ .  
 26       *Remarks:* This function shall not participate in overload resolution unless there is exactly one occurrence  
       of  $T$  in  $\text{Types} \dots$  and  $\text{is\_constructible\_v}\langle T, \text{initializer\_list}\langle U \rangle \&, \text{Args} \dots \rangle$  is  $\text{true}$ . If  $T$ 's  
       selected constructor is a `constexpr` constructor, this constructor shall be a `constexpr` constructor.

```
template<size_t I, class... Args> constexpr explicit variant(in_place_index_t<I>, Args&&... args);
```

27       *Effects:* Initializes the contained value as if direct-non-list-initializing an object of type  $T_I$  with the  
       arguments `std::forward<Args>(args)`....

28       *Postconditions:* `index()` is  $I$ .

29       *Throws:* Any exception thrown by calling the selected constructor of  $T_I$ .

30       *Remarks:* This function shall not participate in overload resolution unless

(30.1)     —  $I$  is less than `sizeof...`( $\text{Types}$ ) and

(30.2)     —  $\text{is\_constructible\_v}\langle T_I, \text{Args} \dots \rangle$  is  $\text{true}$ .

If  $T_I$ 's selected constructor is a `constexpr` constructor, this constructor shall be a `constexpr` constructor.

```
template<size_t I, class U, class... Args>
constexpr explicit variant(in_place_index_t<I>, initializer_list<U> il, Args&&... args);
```

31       *Effects:* Initializes the contained value as if direct-non-list-initializing an object of type  $T_I$  with the  
       arguments `il`, `std::forward<Args>(args)`....

32       *Postconditions:* `index()` is  $I$ .

33       *Remarks:* This function shall not participate in overload resolution unless

(33.1)     —  $I$  is less than `sizeof...`( $\text{Types}$ ) and

(33.2)     —  $\text{is\_constructible\_v}\langle T_I, \text{initializer\_list}\langle U \rangle \&, \text{Args} \dots \rangle$  is  $\text{true}$ .

If  $T_I$ 's selected constructor is a `constexpr` constructor, this constructor shall be a `constexpr` constructor.

### 23.7.3.2 Destructor

[variant.dtor]

```
~variant();
```

1       *Effects:* If `valueless_by_exception()` is `false`, destroys the currently contained value.

2       *Remarks:* If `is_trivially_destructible_v<T_i> == true` for all  $T_i$  then this destructor shall be a  
       trivial destructor.

### 23.7.3.3 Assignment

[variant.assign]

```
variant& operator=(const variant& rhs);
```

1       Let  $j$  be `rhs.index()`.

2       *Effects:*

- (2.1)     — If neither `*this` nor `rhs` holds a value, there is no effect.
- (2.2)     — Otherwise, if `*this` holds a value but `rhs` does not, destroys the value contained in `*this` and  
       sets `*this` to not hold a value.
- (2.3)     — Otherwise, if `index() == j`, assigns the value contained in `rhs` to the value contained in `*this`.
- (2.4)     — Otherwise, if either `is_nothrow_copy_constructible_v<T_j>` is `true` or `is_nothrow_move_constructible_v<T_j>` is `false`, equivalent to `emplace<j>(get<j>(rhs))`.

- (2.5) — Otherwise, equivalent to `operator=(variant(rhs))`.
- 3     >Returns: `*this`.
- 4     Postconditions: `index() == rhs.index()`.
- 5     Remarks: This operator shall be defined as deleted unless `is_copy_constructible_v<Ti> && is_copy_assignable_v<Ti>` is true for all *i*.

```
variant& operator=(variant&& rhs) noexcept(see below);
```

- 6     Let *j* be `rhs.index()`.
- 7     Effects:
- (7.1) — If neither `*this` nor `rhs` holds a value, there is no effect.
- (7.2) — Otherwise, if `*this` holds a value but `rhs` does not, destroys the value contained in `*this` and sets `*this` to not hold a value.
- (7.3) — Otherwise, if `index() == j`, assigns `get<j>(std::move(rhs))` to the value contained in `*this`.
- (7.4) — Otherwise, equivalent to `emplace<j>(get<j>(std::move(rhs)))`.
- 8     >Returns: `*this`.
- 9     Remarks: This function shall not participate in overload resolution unless `is_move_constructible_v<Ti> && is_move_assignable_v<Ti>` is true for all *i*. The expression inside `noexcept` is equivalent to: `is_nothrow_move_constructible_v<Ti> && is_nothrow_move_assignable_v<Ti>` for all *i*.
- (9.1) — If an exception is thrown during the call to  $T_j$ 's move construction (with *j* being `rhs.index()`), the `variant` will hold no value.
- (9.2) — If an exception is thrown during the call to  $T_j$ 's move assignment, the state of the contained value is as defined by the exception safety guarantee of  $T_j$ 's move assignment; `index()` will be *j*.

```
template<class T> variant& operator=(T&& t) noexcept(see below);
```

- 10    Let  $T_j$  be a type that is determined as follows: build an imaginary function  $FUN(T_i)$  for each alternative type  $T_i$ . The overload  $FUN(T_j)$  selected by overload resolution for the expression  $FUN(std::forward<T>(t))$  defines the alternative  $T_j$  which is the type of the contained value after assignment.
- 11    Effects:
- (11.1) — If `*this` holds a  $T_j$ , assigns `std::forward<T>(t)` to the value contained in `*this`.
- (11.2) — Otherwise, if `is_nothrow_constructible_v<Tj, T> || !is_nothrow_move_constructible_v<Tj>` is true, equivalent to `emplace<j>(std::forward<T>(t))`.
- (11.3) — Otherwise, equivalent to `operator=(variant(std::forward<T>(t)))`.
- 12    Postconditions: `holds_alternative<Tj is true, with  $T_j$  selected by the imaginary function overload resolution described above.`
- 13    >Returns: `*this`.
- 14    Remarks: This function shall not participate in overload resolution unless
- (14.1) — `is_same_v<remove_cvref_t<T>, variant>` is false,
- (14.2) — `is_assignable_v<Tj&, T> && is_constructible_v<Tj, T>` is true, and
- (14.3) — the expression  $FUN(std::forward<T>(t))$  (with  $FUN$  being the above-mentioned set of imaginary functions) is well-formed.

15        [ *Note:*  
             `variant<string, string> v;`  
             `v = "abc";`

is ill-formed, as both alternative types have an equally viable constructor for the argument. — *end note* ]

16        The expression inside `noexcept` is equivalent to:

`is_nothrow_assignable_v<Tj&, T> && is_nothrow_constructible_v<Tj, T>`

- (16.1) — If an exception is thrown during the assignment of `std::forward<T>(t)` to the value contained in `*this`, the state of the contained value and `t` are as defined by the exception safety guarantee of the assignment expression; `valueless_by_exception()` will be `false`.
- (16.2) — If an exception is thrown during the initialization of the contained value, the `variant` object might not hold a value.

### 23.7.3.4 Modifiers

[`variant.mod`]

`template<class T, class... Args> T& emplace(Args&&... args);`

1        Let  $I$  be the zero-based index of `T` in `Types`....

2        *Effects:* Equivalent to: `return emplace<I>(std::forward<Args>(args)...);`

3        *Remarks:* This function shall not participate in overload resolution unless `is_constructible_v<T, Args...>` is `true`, and `T` occurs exactly once in `Types`....

`template<class T, class U, class... Args> T& emplace(initializer_list<U> il, Args&&... args);`

4        Let  $I$  be the zero-based index of `T` in `Types`....

5        *Effects:* Equivalent to: `return emplace<I>(il, std::forward<Args>(args)...);`

6        *Remarks:* This function shall not participate in overload resolution unless `is_constructible_v<T, initializer_list<U>&, Args...>` is `true`, and `T` occurs exactly once in `Types`....

`template<size_t I, class... Args>`  
`variant_alternative_t<I, variant<Types...>>& emplace(Args&&... args);`

7        *Requires:* `I < sizeof...(Types)`.

8        *Effects:* Destroys the currently contained value if `valueless_by_exception()` is `false`. Then initializes the contained value as if direct-non-list-initializing a value of type  $T_I$  with the arguments `std::forward<Args>(args)....`

9        *Postconditions:* `index()` is  $I$ .

10      *Returns:* A reference to the new contained value.

11      *Throws:* Any exception thrown during the initialization of the contained value.

12      *Remarks:* This function shall not participate in overload resolution unless `is_constructible_v<TI, Args...>` is `true`. If an exception is thrown during the initialization of the contained value, the `variant` might not hold a value.

`template<size_t I, class U, class... Args>`  
`variant_alternative_t<I, variant<Types...>>& emplace(initializer_list<U> il, Args&&... args);`

13      *Requires:* `I < sizeof...(Types)`.

14     *Effects:* Destroys the currently contained value if `valueless_by_exception()` is `false`. Then initializes the contained value as if direct-non-list-initializing a value of type  $T_I$  with the arguments `il`, `std::forward<Args>(args)....`

15     *Postconditions:* `index()` is  $I$ .

16     *Returns:* A reference to the new contained value.

17     *Throws:* Any exception thrown during the initialization of the contained value.

18     *Remarks:* This function shall not participate in overload resolution unless `is_constructible_v<TI>`, `initializer_list<U>&, Args...>` is `true`. If an exception is thrown during the initialization of the contained value, the `variant` might not hold a value.

### 23.7.3.5 Value status

[`variant.status`]

```
constexpr bool valueless_by_exception() const noexcept;
```

1     *Effects:* Returns `false` if and only if the `variant` holds a value.

2     *[Note:* A `variant` might not hold a value if an exception is thrown during a type-changing assignment or emplacement. The latter means that even a `variant<float, int>` can become `valueless_by_exception()`, for instance by

```
struct S { operator int() { throw 42; } };
variant<float, int> v{12.f};
v.emplace<1>(S());
```

— end note]

```
constexpr size_t index() const noexcept;
```

3     *Effects:* If `valueless_by_exception()` is `true`, returns `variant_npos`. Otherwise, returns the zero-based index of the alternative of the contained value.

### 23.7.3.6 Swap

[`variant.swap`]

```
void swap(variant& rhs) noexcept(see below);
```

1     *Requires:* Lvalues of type  $T_i$  shall be swappable (??) and `is_move_constructible_v<Ti>` shall be `true` for all  $i$ .

2     *Effects:*

(2.1)     — If `valueless_by_exception() && rhs.valueless_by_exception()` no effect.

(2.2)     — Otherwise, if `index() == rhs.index()`, calls `swap(get<i>(*this), get<i>(rhs))` where  $i$  is `index()`.

(2.3)     — Otherwise, exchanges values of `rhs` and `*this`.

3     *Throws:* If `index() == rhs.index()`, any exception thrown by `swap(get<i>(*this), get<i>(rhs))` with  $i$  being `index()`. Otherwise, any exception thrown by the move constructor of  $T_i$  or  $T_j$  with  $i$  being `index()` and  $j$  being `rhs.index()`.

4     *Remarks:* If an exception is thrown during the call to function `swap(get<i>(*this), get<i>(rhs))`, the states of the contained values of `*this` and of `rhs` are determined by the exception safety guarantee of `swap` for lvalues of  $T_i$  with  $i$  being `index()`. If an exception is thrown during the exchange of the values of `*this` and `rhs`, the states of the values of `*this` and of `rhs` are determined by the exception

safety guarantee of `variant`'s move constructor. The expression inside `noexcept` is equivalent to the logical AND of `is_nothrow_move_constructible_v<Ti>` && `is_nothrow_swappable_v<Ti>` for all *i*.

### 23.7.4 variant helper classes

[`variant.helper`]

```
template<class T> struct variant_size;
```

- 1     *Remarks:* All specializations of `variant_size` shall meet the `UnaryTypeTrait` requirements (??) with a base characteristic of `integral_constant<size_t, N>` for some N.

```
template<class T> class variant_size<const T>;
template<class T> class variant_size<volatile T>;
template<class T> class variant_size<const volatile T>;
```

- 2     Let VS denote `variant_size<T>` of the cv-unqualified type T. Then each of the three templates shall meet the `UnaryTypeTrait` requirements (??) with a base characteristic of `integral_constant<size_t, VS::value>`.

```
template<class... Types>
struct variant_size<variant<Types...>> : integral_constant<size_t, sizeof...(Types)> { };

template<size_t I, class T> class variant_alternative<I, const T>;
template<size_t I, class T> class variant_alternative<I, volatile T>;
template<size_t I, class T> class variant_alternative<I, const volatile T>;
```

- 3     Let VA denote `variant_alternative<I, T>` of the cv-unqualified type T. Then each of the three templates shall meet the `TransformationTrait` requirements (??) with a member `typedef type` that names the following type:

- (3.1) — for the first specialization, `add_const_t<VA::type>`,
- (3.2) — for the second specialization, `add_VOLATILE_t<VA::type>`, and
- (3.3) — for the third specialization, `add_cv_t<VA::type>`.

```
variant_alternative<I, variant<Types...>>::type
```

- 4     *Requires:* `I < sizeof...(Types)`. The program is ill-formed if I is out of bounds.

- 5     *Value:* The type  $T_I$ .

### 23.7.5 Value access

[`variant.get`]

```
template<class T, class... Types>
constexpr bool holds_alternative(const variant<Types...>& v) noexcept;
```

- 1     *Requires:* The type T occurs exactly once in `Types....` Otherwise, the program is ill-formed.

- 2     *Returns:* true if `index()` is equal to the zero-based index of T in `Types....`

```
template<size_t I, class... Types>
constexpr variant_alternative_t<I, variant<Types...>>& get(variant<Types...>& v);
template<size_t I, class... Types>
constexpr variant_alternative_t<I, variant<Types...>>&& get(variant<Types...>&& v);
template<size_t I, class... Types>
constexpr const variant_alternative_t<I, variant<Types...>>& get(const variant<Types...>& v);
```

```

template<size_t I, class... Types>
constexpr const variant_alternative_t<I, variant<Types...>>&& get(const variant<Types...>&& v);
3   Requires: I < sizeof...(Types). Otherwise the program is ill-formed.
4   Effects: If v.index() is I, returns a reference to the object stored in the variant. Otherwise, throws
     an exception of type bad_variant_access.

```

```

template<class T, class... Types> constexpr T& get(variant<Types...>& v);
template<class T, class... Types> constexpr T&& get(variant<Types...>&& v);
template<class T, class... Types> constexpr const T& get(const variant<Types...>& v);
template<class T, class... Types> constexpr const T&& get(const variant<Types...>&& v);
5   Requires: The type T occurs exactly once in Types.... Otherwise, the program is ill-formed.
6   Effects: If v holds a value of type T, returns a reference to that value. Otherwise, throws an exception
     of type bad_variant_access.

```

```

template<size_t I, class... Types>
constexpr add_pointer_t<variant_alternative_t<I, variant<Types...>>>
  get_if(variant<Types...>* v) noexcept;
template<size_t I, class... Types>
constexpr add_pointer_t<const variant_alternative_t<I, variant<Types...>>>
  get_if(const variant<Types...>* v) noexcept;
7   Requires: I < sizeof...(Types). Otherwise the program is ill-formed.
8   Returns: A pointer to the value stored in the variant, if v != nullptr and v->index() == I.
     Otherwise, returns nullptr.

```

```

template<class T, class... Types>
constexpr add_pointer_t<T>
  get_if(variant<Types...>* v) noexcept;
template<class T, class... Types>
constexpr add_pointer_t<const T>
  get_if(const variant<Types...>* v) noexcept;
9   Requires: The type T occurs exactly once in Types.... Otherwise, the program is ill-formed.
10  Effects: Equivalent to: return get_if<i>(v); with i being the zero-based index of T in Types....
```

### 23.7.6 Relational operators

[`variant.relops`]

```

template<class... Types>
constexpr bool operator==(const variant<Types...>& v, const variant<Types...>& w);
1   Requires: get<i>(v) == get<i>(w) is a valid expression returning a type that is convertible to bool,
     for all i.
2   Returns: If v.index() != w.index(), false; otherwise if v.valueless_by_exception(), true; otherwise
     get<i>(v) == get<i>(w) with i being v.index().

```

```

template<class... Types>
constexpr bool operator!=(const variant<Types...>& v, const variant<Types...>& w);
3   Requires: get<i>(v) != get<i>(w) is a valid expression returning a type that is convertible to bool,
     for all i.

```

4     *Returns:* If `v.index() != w.index()`, `true`; otherwise if `v.valueless_by_exception()`, `false`; otherwise `get<i>(v) != get<i>(w)` with  $i$  being `v.index()`.

```
template<class... Types>
constexpr bool operator<(const variant<Types...>& v, const variant<Types...>& w);
```

5     *Requires:* `get<i>(v) < get<i>(w)` is a valid expression returning a type that is convertible to `bool`, for all  $i$ .

6     *Returns:* If `w.valueless_by_exception()`, `false`; otherwise if `v.valueless_by_exception()`, `true`; otherwise, if `v.index() < w.index()`, `true`; otherwise if `v.index() > w.index()`, `false`; otherwise `get<i>(v) < get<i>(w)` with  $i$  being `v.index()`.

```
template<class... Types>
constexpr bool operator>(const variant<Types...>& v, const variant<Types...>& w);
```

7     *Requires:* `get<i>(v) > get<i>(w)` is a valid expression returning a type that is convertible to `bool`, for all  $i$ .

8     *Returns:* If `v.valueless_by_exception()`, `false`; otherwise if `w.valueless_by_exception()`, `true`; otherwise, if `v.index() > w.index()`, `true`; otherwise if `v.index() < w.index()`, `false`; otherwise `get<i>(v) > get<i>(w)` with  $i$  being `v.index()`.

```
template<class... Types>
constexpr bool operator<=(const variant<Types...>& v, const variant<Types...>& w);
```

9     *Requires:* `get<i>(v) <= get<i>(w)` is a valid expression returning a type that is convertible to `bool`, for all  $i$ .

10    *Returns:* If `v.valueless_by_exception()`, `true`; otherwise if `w.valueless_by_exception()`, `false`; otherwise, if `v.index() < w.index()`, `true`; otherwise if `v.index() > w.index()`, `false`; otherwise `get<i>(v) <= get<i>(w)` with  $i$  being `v.index()`.

```
template<class... Types>
constexpr bool operator>=(const variant<Types...>& v, const variant<Types...>& w);
```

11    *Requires:* `get<i>(v) >= get<i>(w)` is a valid expression returning a type that is convertible to `bool`, for all  $i$ .

12    *Returns:* If `w.valueless_by_exception()`, `true`; otherwise if `v.valueless_by_exception()`, `false`; otherwise, if `v.index() > w.index()`, `true`; otherwise if `v.index() < w.index()`, `false`; otherwise `get<i>(v) >= get<i>(w)` with  $i$  being `v.index()`.

### 23.7.7 Visitation

[[variant.visit](#)]

```
template<class Visitor, class... Variants>
constexpr see below visit(Visitor&& vis, Variants&&... vars);
```

- 1     *Requires:* The expression in the *Effects*: element shall be a valid expression of the same type and value category, for all combinations of alternative types of all variants. Otherwise, the program is ill-formed.
- 2     *Effects:* Let `is...` be `vars.index()`. . . . Returns `INVOKE(forward<Visitor>(vis), get<is>(forward<Variants>(vars))...); (??).`
- 3     *Remarks:* The return type is the common type of all possible *INVOKE* expressions of the *Effects*: element.
- 4     *Throws:* `bad_variant_access` if any variant in `vars` is `valueless_by_exception()`.

<sup>5</sup> *Complexity:* For `sizeof...(Variants) <= 1`, the invocation of the callable object is implemented in constant time, i.e., it does not depend on `sizeof...(Types)`. For `sizeof...(Variants) > 1`, the invocation of the callable object has no complexity requirements.

### 23.7.8 Class monostate

[variant.monostate]

```
struct monostate{};
```

<sup>1</sup> The class `monostate` can serve as a first alternative type for a `variant` to make the `variant` type default constructible.

### 23.7.9 monostate relational operators

[variant.monostate.relops]

```
constexpr bool operator<(monostate, monostate) noexcept { return false; }
constexpr bool operator>(monostate, monostate) noexcept { return false; }
constexpr bool operator<=(monostate, monostate) noexcept { return true; }
constexpr bool operator>=(monostate, monostate) noexcept { return true; }
constexpr bool operator==(monostate, monostate) noexcept { return true; }
constexpr bool operator!=(monostate, monostate) noexcept { return false; }
```

<sup>1</sup> [ *Note:* `monostate` objects have only a single state; they thus always compare equal. — end note]

### 23.7.10 Specialized algorithms

[variant.specalg]

```
template<class... Types>
void swap(variant<Types...>& v, variant<Types...>& w) noexcept(see below);
```

<sup>1</sup> *Effects:* Equivalent to `v.swap(w)`.

<sup>2</sup> *Remarks:* This function shall not participate in overload resolution unless `is_move_constructible_v<Ti> && is_swappable_v<Ti>` is `true` for all *i*. The expression inside `noexcept` is equivalent to `noexcept(v.swap(w))`.

### 23.7.11 Class bad\_variant\_access

[variant.bad.access]

```
class bad_variant_access : public exception {
public:
    bad_variant_access() noexcept;
    const char* what() const noexcept override;
};
```

<sup>1</sup> Objects of type `bad_variant_access` are thrown to report invalid accesses to the value of a `variant` object.

```
bad_variant_access() noexcept;
```

<sup>2</sup> Constructs a `bad_variant_access` object.

```
const char* what() const noexcept override;
```

<sup>3</sup> *Returns:* An implementation-defined NTBS.

### 23.7.12 Hash support

[variant.hash]

```
template<class... Types> struct hash<variant<Types...>>;
```

<sup>1</sup> The specialization `hash<variant<Types...>>` is enabled (??) if and only if every specialization in `hash<remove_const_t<Types>>...` is enabled. The member functions are not guaranteed to be `noexcept`.

```
template<> struct hash<monostate>;
```

- <sup>2</sup> The specialization is enabled (??).

## 23.8 Storage for any type

[any]

- <sup>1</sup> This subclause describes components that C++ programs may use to perform operations on objects of a discriminated type.
- <sup>2</sup> [Note: The discriminated type may contain values of different types but does not attempt conversion between them, i.e., 5 is held strictly as an `int` and is not implicitly convertible either to "5" or to 5.0. This indifference to interpretation but awareness of type effectively allows safe, generic containers of single values, with no scope for surprises from ambiguous conversions. —end note]

### 23.8.1 Header <any> synopsis

[any.synop]

```
namespace std {
    // ??, class bad_any_cast
    class bad_any_cast;

    // ??, class any
    class any;

    // ??, non-member functions
    void swap(any& x, any& y) noexcept;

    template<class T, class... Args>
        any make_any(Args&& ...args);
    template<class T, class U, class... Args>
        any make_any(initializer_list<U> il, Args&& ...args);

    template<class T>
        T any_cast(const any& operand);
    template<class T>
        T any_cast(any& operand);
    template<class T>
        T any_cast(any&& operand);

    template<class T>
        const T* any_cast(const any* operand) noexcept;
    template<class T>
        T* any_cast(any* operand) noexcept;
}
```

### 23.8.2 Class bad\_any\_cast

[any.bad\_any\_cast]

```
class bad_any_cast : public bad_cast {
public:
    const char* what() const noexcept override;
};
```

- <sup>1</sup> Objects of type `bad_any_cast` are thrown by a failed `any_cast` (??).

`const char* what() const noexcept override;`

<sup>2</sup> *Returns:* An implementation-defined NTBS.

<sup>3</sup> *Remarks:* The message may be a null-terminated multibyte string (??), suitable for conversion and display as a wstring (??, ??).

### 23.8.3 Class any

[any.class]

```
class any {
public:
    // ??, construction and destruction
    constexpr any() noexcept;

    any(const any& other);
    any(any&& other) noexcept;

    template<class T> any(T&& value);

    template<class T, class... Args>
        explicit any(in_place_type_t<T>, Args&&...);
    template<class T, class U, class... Args>
        explicit any(in_place_type_t<T>, initializer_list<U>, Args&&...);

    ~any();

    // ??, assignments
    any& operator=(const any& rhs);
    any& operator=(any&& rhs) noexcept;

    template<class T> any& operator=(T&& rhs);

    // ??, modifiers
    template<class T, class... Args>
        decay_t<T>& emplace(Args&& ...);
    template<class T, class U, class... Args>
        decay_t<T>& emplace(initializer_list<U>, Args&&...);
    void reset() noexcept;
    void swap(any& rhs) noexcept;

    // ??, observers
    bool has_value() const noexcept;
    const type_info& type() const noexcept;
};
```

- <sup>1</sup> An object of class `any` stores an instance of any type that satisfies the constructor requirements or it has no value, and this is referred to as the *state* of the class `any` object. The stored instance is called the *contained value*. Two states are equivalent if either they both have no value, or both have a value and the contained values are equivalent.
- <sup>2</sup> The non-member `any_cast` functions provide type-safe access to the contained value.

- <sup>3</sup> Implementations should avoid the use of dynamically allocated memory for a small contained value. [*Example:* where the object constructed is holding only an `int`. — *end example*] Such small-object optimization shall only be applied to types T for which `is_nothrow_move_constructible_v<T>` is `true`.

### 23.8.3.1 Construction and destruction

[any.cons]

```
constexpr any() noexcept;
```

- 1     *Postconditions:* `has_value()` is `false`.

```
any(const any& other);
```

- 2     *Effects:* If `other.has_value()` is `false`, constructs an object that has no value. Otherwise, equivalent to `any(in_place_type<T>, any_cast<const T&>(other))` where T is the type of the contained value.

- 3     *Throws:* Any exceptions arising from calling the selected constructor for the contained value.

```
any(any&& other) noexcept;
```

- 4     *Effects:* If `other.has_value()` is `false`, constructs an object that has no value. Otherwise, constructs an object of type `any` that contains either the contained value of `other`, or contains an object of the same type constructed from the contained value of `other` considering that contained value as an rvalue.

- 5     *Postconditions:* `other` is left in a valid but otherwise unspecified state.

```
template<class T>
any(T&& value);
```

- 6     Let VT be `decay_t<T>`.

- 7     *Requires:* VT shall satisfy the `CopyConstructible` requirements.

- 8     *Effects:* Constructs an object of type `any` that contains an object of type VT direct-initialized with `std::forward<T>(value)`.

- 9     *Remarks:* This constructor shall not participate in overload resolution unless VT is not the same type as `any`, VT is not a specialization of `in_place_type_t`, and `is_copy_constructible_v<VT>` is `true`.

- 10    *Throws:* Any exception thrown by the selected constructor of VT.

```
template<class T, class... Args>
explicit any(in_place_type_t<T>, Args&&... args);
```

- 11    Let VT be `decay_t<T>`.

- 12    *Requires:* VT shall satisfy the `CopyConstructible` requirements.

- 13    *Effects:* Initializes the contained value as if direct-non-list-initializing an object of type VT with the arguments `std::forward<Args>(args)....`

- 14    *Postconditions:* `*this` contains a value of type VT.

- 15    *Throws:* Any exception thrown by the selected constructor of VT.

- 16    *Remarks:* This constructor shall not participate in overload resolution unless `is_copy_constructible_v<VT>` is `true` and `is_constructible_v<VT, Args...>` is `true`.

```
template<class T, class U, class... Args>
explicit any(in_place_type_t<T>, initializer_list<U> il, Args&&... args);
```

- 17    Let VT be `decay_t<T>`.

- 18    *Requires:* VT shall satisfy the `CopyConstructible` requirements.

19     *Effects:* Initializes the contained value as if direct-non-list-initializing an object of type VT with the  
     arguments `il, std::forward<Args>(args)....`

20     *Postconditions:* `*this` contains a value.

21     *Throws:* Any exception thrown by the selected constructor of VT.

22     *Remarks:* This constructor shall not participate in overload resolution unless `is_copy_constructible_v<VT>` is true and `is_constructible_v<VT, initializer_list<U>&, Args...>` is true.

23     `~any();`

23     *Effects:* As if by `reset()`.

### 23.8.3.2 Assignment

[any.assign]

```
any& operator=(const any& rhs);
```

1     *Effects:* As if by `any(rhs).swap(*this)`. No effects if an exception is thrown.

2     *Returns:* `*this`.

3     *Throws:* Any exceptions arising from the copy constructor for the contained value.

```
any& operator=(any&& rhs) noexcept;
```

4     *Effects:* As if by `any(std::move(rhs)).swap(*this)`.

5     *Returns:* `*this`.

6     *Postconditions:* The state of `*this` is equivalent to the original state of `rhs` and `rhs` is left in a valid  
     but otherwise unspecified state.

```
template<class T>
any& operator=(T&& rhs);
```

7     Let VT be `decay_t<T>`.

8     *Requires:* VT shall satisfy the CopyConstructible requirements.

9     *Effects:* Constructs an object tmp of type any that contains an object of type VT direct-initialized with  
     `std::forward<T>(rhs)`, and `tmp.swap(*this)`. No effects if an exception is thrown.

10    *Returns:* `*this`.

11    *Remarks:* This operator shall not participate in overload resolution unless VT is not the same type as  
     any and `is_copy_constructible_v<VT>` is true.

12    *Throws:* Any exception thrown by the selected constructor of VT.

### 23.8.3.3 Modifiers

[any.modifiers]

```
template<class T, class... Args>
decay_t<T>& emplace(Args&&... args);
```

1     Let VT be `decay_t<T>`.

2     *Requires:* VT shall satisfy the CopyConstructible requirements.

3     *Effects:* Calls `reset()`. Then initializes the contained value as if direct-non-list-initializing an object of  
     type VT with the arguments `std::forward<Args>(args)....`

4     *Postconditions:* `*this` contains a value.

5     *Returns:* A reference to the new contained value.

6       *Throws:* Any exception thrown by the selected constructor of VT.

7       *Remarks:* If an exception is thrown during the call to VT's constructor, `*this` does not contain a value, and any previously contained value has been destroyed. This function shall not participate in overload resolution unless `is_copy_constructible_v<VT>` is `true` and `is_constructible_v<VT, Args...>` is `true`.

```
template<class T, class U, class... Args>
decay_t<T>& emplace(initializer_list<U> il, Args&&... args);
```

8       Let VT be `decay_t<T>`.

9       *Requires:* VT shall satisfy the `CopyConstructible` requirements.

10      *Effects:* Calls `reset()`. Then initializes the contained value as if direct-non-list-initializing an object of type VT with the arguments `il, std::forward<Args>(args)....`

11      *Postconditions:* `*this` contains a value.

12      *Returns:* A reference to the new contained value.

13      *Throws:* Any exception thrown by the selected constructor of VT.

14      *Remarks:* If an exception is thrown during the call to VT's constructor, `*this` does not contain a value, and any previously contained value has been destroyed. The function shall not participate in overload resolution unless `is_copy_constructible_v<VT>` is `true` and `is_constructible_v<VT, initializer_list<U>&, Args...>` is `true`.

```
void reset() noexcept;
```

15      *Effects:* If `has_value()` is `true`, destroys the contained value.

16      *Postconditions:* `has_value()` is `false`.

```
void swap(any& rhs) noexcept;
```

17      *Effects:* Exchanges the states of `*this` and `rhs`.

### 23.8.3.4 Observers

[any.observers]

```
bool has_value() const noexcept;
```

1       *Returns:* `true` if `*this` contains an object, otherwise `false`.

```
const type_info& type() const noexcept;
```

2       *Returns:* `typeid(T)` if `*this` has a contained value of type T, otherwise `typeid(void)`.

3       *[Note:* Useful for querying against types known either at compile time or only at runtime. — end note]

### 23.8.4 Non-member functions

[any.nonmembers]

```
void swap(any& x, any& y) noexcept;
```

1       *Effects:* As if by `x.swap(y)`.

```
template<class T, class... Args>
```

```
any make_any(Args&& ...args);
```

2       *Effects:* Equivalent to: `return any(in_place_type<T>, std::forward<Args>(args)...);`

```

template<class T, class U, class... Args>
any make_any(initializer_list<U> il, Args&& ...args);

3   Effects: Equivalent to: return any(in_place_type<T>, il, std::forward<Args>(args)...);

template<class T>
T any_cast(const any& operand);
template<class T>
T any_cast(any& operand);
template<class T>
T any_cast(any&& operand);

4   Let U be the type remove_cvref_t<T>.

5   Requires: For the first overload, is_constructible_v<T, const U&> is true. For the second overload,
is_constructible_v<T, U&> is true. For the third overload, is_constructible_v<T, U> is true.
Otherwise the program is ill-formed.

6   Returns: For the first and second overload, static_cast<T>(*any_cast<U>(&operand)). For the
third overload, static_cast<T>(std::move(*any_cast<U>(&operand))).

7   Throws: bad_any_cast if operand.type() != typeid(remove_reference_t<T>).

8   [ Example:

    any x(5);                                // x holds int
    assert(any_cast<int>(x) == 5);              // cast to value
    any_cast<int&>(x) = 10;                   // cast to reference
    assert(any_cast<int>(x) == 10);

    x = "Meow";                               // x holds const char*
    assert(strcmp(any_cast<const char*>(x), "Meow") == 0);
    any_cast<const char*&>(x) = "Harry";
    assert(strcmp(any_cast<const char*>(x), "Harry") == 0);

    x = string("Meow");                      // x holds string
    string s, s2("Jane");
    s = move(any_cast<string>(x));           // move from any
    assert(s == "Meow");
    any_cast<string&>(x) = move(s2);          // move to any
    assert(any_cast<const string>(x) == "Jane");

    string cat("Meow");
    const any y(cat);                        // const y holds string
    assert(any_cast<const string>(y) == cat);

    any_cast<string&>(y);                  // error; cannot
                                            // any_cast away const
  — end example]

template<class T>
const T* any_cast(const any* operand) noexcept;

```

```

template<class T>
T* any_cast(any* operand) noexcept;

9   Returns: If operand != nullptr && operand->type() == typeid(T), a pointer to the object con-
     tained by operand; otherwise, nullptr.

10  [ Example:
      bool is_string(const any& operand) {
          return any_cast<string>(&operand) != nullptr;
      }
      — end example ]
  
```

## 23.9 Bitsets

[bitset]

### 23.9.1 Header <bitset> synopsis

[bitset.syn]

```

#include <string>
#include <iostream> // for istream (??), ostream (??), see ???

namespace std {
    template<size_t N> class bitset;

    // ??, bitset operators
    template<size_t N>
        bitset<N> operator&(const bitset<N>&, const bitset<N>&) noexcept;
    template<size_t N>
        bitset<N> operator|(const bitset<N>&, const bitset<N>&) noexcept;
    template<size_t N>
        bitset<N> operator^(const bitset<N>&, const bitset<N>&) noexcept;
    template<class charT, class traits, size_t N>
        basic_istream<charT, traits>&
            operator>>(basic_istream<charT, traits>& is, bitset<N>& x);
    template<class charT, class traits, size_t N>
        basic_ostream<charT, traits>&
            operator<<(basic_ostream<charT, traits>& os, const bitset<N>& x);
}

1 The header <bitset> defines a class template and several related functions for representing and manipulating
fixed-size sequences of bits.
  
```

### 23.9.2 Class template bitset

[template.bitset]

```

namespace std {
    template<size_t N> class bitset {
        public:
            // bit reference
            class reference {
                friend class bitset;
                reference() noexcept;

                public:
                    ~reference() noexcept;
                    reference& operator=(bool x) noexcept; // for b[i] = x;
            };
    };
}
  
```

```

    reference& operator=(const reference&) noexcept; // for b[i] = b[j];
    bool operator~() const noexcept; // flips the bit
    operator bool() const noexcept; // for x = b[i];
    reference& flip() noexcept; // for b[i].flip();
};

// ??, constructors
constexpr bitset() noexcept;
constexpr bitset(unsigned long long val) noexcept;
template<class charT, class traits, class Allocator>
explicit bitset(
    const basic_string<charT, traits, Allocator>& str,
    typename basic_string<charT, traits, Allocator>::size_type pos = 0,
    typename basic_string<charT, traits, Allocator>::size_type n
        = basic_string<charT, traits, Allocator>::npos,
    charT zero = charT('0'),
    charT one = charT('1'));
template<class charT>
explicit bitset(
    const charT* str,
    typename basic_string<charT>::size_type n = basic_string<charT>::npos,
    charT zero = charT('0'),
    charT one = charT('1'));

// ??, bitset operations
bitset<N>& operator&=(const bitset<N>& rhs) noexcept;
bitset<N>& operator|=(const bitset<N>& rhs) noexcept;
bitset<N>& operator^=(const bitset<N>& rhs) noexcept;
bitset<N>& operator<=(size_t pos) noexcept;
bitset<N>& operator>=(size_t pos) noexcept;
bitset<N>& set() noexcept;
bitset<N>& set(size_t pos, bool val = true);
bitset<N>& reset() noexcept;
bitset<N>& reset(size_t pos);
bitset<N> operator~() const noexcept;
bitset<N>& flip() noexcept;
bitset<N>& flip(size_t pos);

// element access
constexpr bool operator[](size_t pos) const; // for b[i];
reference operator[](size_t pos); // for b[i];

unsigned long to_ulong() const;
unsigned long long to_ullong() const;
template<class charT = char,
         class traits = char_traits<charT>,
         class Allocator = allocator<charT>>
basic_string<charT, traits, Allocator>
to_string(charT zero = charT('0'), charT one = charT('1')) const;

```

```

    size_t count() const noexcept;
    constexpr size_t size() const noexcept;
    bool operator==(const bitset<N>& rhs) const noexcept;
    bool operator!=(const bitset<N>& rhs) const noexcept;
    bool test(size_t pos) const;
    bool all() const noexcept;
    bool any() const noexcept;
    bool none() const noexcept;
    bitset<N> operator<<(size_t pos) const noexcept;
    bitset<N> operator>>(size_t pos) const noexcept;
};

// ??, hash support
template<class T> struct hash;
template<size_t N> struct hash<bitset<N>>;
}

```

- <sup>1</sup> The class template `bitset<N>` describes an object that can store a sequence consisting of a fixed number of bits,  $N$ .
- <sup>2</sup> Each bit represents either the value zero (reset) or one (set). To *toggle* a bit is to change the value zero to one, or the value one to zero. Each bit has a non-negative position `pos`. When converting between an object of class `bitset<N>` and a value of some integral type, bit position `pos` corresponds to the *bit value* `1 << pos`. The integral value corresponding to two or more bits is the sum of their bit values.
- <sup>3</sup> The functions described in this subclause can report three kinds of errors, each associated with a distinct exception:
  - (3.1) — an *invalid-argument* error is associated with exceptions of type `invalid_argument` (??);
  - (3.2) — an *out-of-range* error is associated with exceptions of type `out_of_range` (??);
  - (3.3) — an *overflow* error is associated with exceptions of type `overflow_error` (??).

### 23.9.2.1 bitset constructors

[bitset.cons]

```
constexpr bitset() noexcept;
```

- <sup>1</sup> *Effects:* Constructs an object of class `bitset<N>`, initializing all bits to zero.

```
constexpr bitset(unsigned long long val) noexcept;
```

- <sup>2</sup> *Effects:* Constructs an object of class `bitset<N>`, initializing the first  $M$  bit positions to the corresponding bit values in `val`.  $M$  is the smaller of  $N$  and the number of bits in the value representation (??) of `unsigned long long`. If  $M < N$ , the remaining bit positions are initialized to zero.

```
template<class charT, class traits, class Allocator>
explicit bitset(
    const basic_string<charT, traits, Allocator>& str,
    typename basic_string<charT, traits, Allocator>::size_type pos = 0,
    typename basic_string<charT, traits, Allocator>::size_type n
        = basic_string<charT, traits, Allocator>::npos,
    charT zero = charT('0'),
```

```
charT one = charT('1');
```

3     *Throws:* `out_of_range` if `pos > str.size()` or `invalid_argument` if an invalid character is found (see below).

4     *Effects:* Determines the effective length `rlen` of the initializing string as the smaller of `n` and `str.size() - pos`.

The function then throws `invalid_argument` if any of the `rlen` characters in `str` beginning at position `pos` is other than `zero` or `one`. The function uses `traits::eq()` to compare the character values.

Otherwise, the function constructs an object of class `bitset<N>`, initializing the first `M` bit positions to values determined from the corresponding characters in the string `str`. `M` is the smaller of `N` and `rلن`.

5     An element of the constructed object has value zero if the corresponding character in `str`, beginning at position `pos`, is `zero`. Otherwise, the element has the value `one`. Character position `pos + M - 1` corresponds to bit position zero. Subsequent decreasing character positions correspond to increasing bit positions.

6     If `M < N`, remaining bit positions are initialized to zero.

```
template<class charT>
explicit bitset(
    const charT* str,
    typename basic_string<charT>::size_type n = basic_string<charT>::npos,
    charT zero = charT('0'),
    charT one = charT('1'));
```

7     *Effects:* Constructs an object of class `bitset<N>` as if by:

```
bitset(n == basic_string<charT>::npos
       ? basic_string<charT>(str)
       : basic_string<charT>(str, n),
       0, n, zero, one)
```

### 23.9.2.2 bitset members

[[bitset.members](#)]

```
bitset<N>& operator&=(const bitset<N>& rhs) noexcept;
```

1     *Effects:* Clears each bit in `*this` for which the corresponding bit in `rhs` is clear, and leaves all other bits unchanged.

2     *Returns:* `*this`.

```
bitset<N>& operator|=(const bitset<N>& rhs) noexcept;
```

3     *Effects:* Sets each bit in `*this` for which the corresponding bit in `rhs` is set, and leaves all other bits unchanged.

4     *Returns:* `*this`.

```
bitset<N>& operator^=(const bitset<N>& rhs) noexcept;
```

5     *Effects:* Toggles each bit in `*this` for which the corresponding bit in `rhs` is set, and leaves all other bits unchanged.

6     *Returns:* `*this`.

```
bitset<N>& operator<<=(size_t pos) noexcept;
```

7       *Effects:* Replaces each bit at position I in \*this with a value determined as follows:

(7.1)     — If I < pos, the new value is zero;

(7.2)     — If I >= pos, the new value is the previous value of the bit at position I - pos.

8       *Returns:* \*this.

```
bitset<N>& operator>>=(size_t pos) noexcept;
```

9       *Effects:* Replaces each bit at position I in \*this with a value determined as follows:

(9.1)     — If pos >= N - I, the new value is zero;

(9.2)     — If pos < N - I, the new value is the previous value of the bit at position I + pos.

10      *Returns:* \*this.

```
bitset<N>& set() noexcept;
```

11      *Effects:* Sets all bits in \*this.

12      *Returns:* \*this.

```
bitset<N>& set(size_t pos, bool val = true);
```

13      *Throws:* out\_of\_range if pos does not correspond to a valid bit position.

14      *Effects:* Stores a new value in the bit at position pos in \*this. If val is true, the stored value is one, otherwise it is zero.

15      *Returns:* \*this.

```
bitset<N>& reset() noexcept;
```

16      *Effects:* Resets all bits in \*this.

17      *Returns:* \*this.

```
bitset<N>& reset(size_t pos);
```

18      *Throws:* out\_of\_range if pos does not correspond to a valid bit position.

19      *Effects:* Resets the bit at position pos in \*this.

20      *Returns:* \*this.

```
bitset<N> operator~() const noexcept;
```

21      *Effects:* Constructs an object x of class bitset<N> and initializes it with \*this.

22      *Returns:* x.flip().

```
bitset<N>& flip() noexcept;
```

23      *Effects:* Toggles all bits in \*this.

24      *Returns:* \*this.

```
bitset<N>& flip(size_t pos);
```

25      *Throws:* out\_of\_range if pos does not correspond to a valid bit position.

26      *Effects:* Toggles the bit at position pos in \*this.

27      *Returns:* \*this.

```

    unsigned long to_ulong() const;

28     Throws: overflow_error if the integral value x corresponding to the bits in *this cannot be represented
         as type unsigned long.
29
30     Returns: x.
31

    unsigned long long to_ullong() const;

30     Throws: overflow_error if the integral value x corresponding to the bits in *this cannot be represented
         as type unsigned long long.
31
32     Returns: x.
33

template<class charT = char,
          class traits = char_traits<charT>,
          class Allocator = allocator<charT>>
basic_string<charT, traits, Allocator>
    to_string(charT zero = charT('0'), charT one = charT('1')) const;

32     Effects: Constructs a string object of the appropriate type and initializes it to a string of length
         N characters. Each character is determined by the value of its corresponding bit position in *this.
         Character position N - 1 corresponds to bit position zero. Subsequent decreasing character positions
         correspond to increasing bit positions. Bit value zero becomes the character zero, bit value one becomes
         the character one.
33
34     Returns: The created object.

    size_t count() const noexcept;

34     Returns: A count of the number of bits set in *this.
35

    constexpr size_t size() const noexcept;

35     Returns: N.
36

    bool operator==(const bitset<N>& rhs) const noexcept;

36     Returns: true if the value of each bit in *this equals the value of the corresponding bit in rhs.
37

    bool operator!=(const bitset<N>& rhs) const noexcept;

37     Returns: true if (*this == rhs).
38

    bool test(size_t pos) const;

38     Throws: out_of_range if pos does not correspond to a valid bit position.
39
39     Returns: true if the bit at position pos in *this has the value one.
40

    bool all() const noexcept;

40     Returns: count() == size().
41

    bool any() const noexcept;

41     Returns: count() != 0.
42

    bool none() const noexcept;

42     Returns: count() == 0.

```

```

bitset<N> operator<<(size_t pos) const noexcept;
43   Returns: bitset<N>(*this) <= pos.

bitset<N> operator>>(size_t pos) const noexcept;
44   Returns: bitset<N>(*this) >= pos.

constexpr bool operator[](size_t pos) const;
45   Requires: pos shall be valid.
46   Returns: true if the bit at position pos in *this has the value one, otherwise false.
47   Throws: Nothing.

bitset<N>::reference operator[](size_t pos);
48   Requires: pos shall be valid.
49   Returns: An object of type bitset<N>::reference such that (*this)[pos] == this->test(pos),
      and such that (*this)[pos] = val is equivalent to this->set(pos, val).
50   Throws: Nothing.

51   Remarks: For the purpose of determining the presence of a data race (??), any access or update through
      the resulting reference potentially accesses or modifies, respectively, the entire underlying bitset.

```

### 23.9.3 bitset hash support

[bitset.hash]

```
template<size_t N> struct hash<bitset<N>>;
```

1 The specialization is enabled (??).

### 23.9.4 bitset operators

[bitset.operators]

```
bitset<N> operator&(const bitset<N>& lhs, const bitset<N>& rhs) noexcept;
```

1 Returns: bitset<N>(lhs) &= rhs.

```
bitset<N> operator|(const bitset<N>& lhs, const bitset<N>& rhs) noexcept;
```

2 Returns: bitset<N>(lhs) |= rhs.

```
bitset<N> operator^(const bitset<N>& lhs, const bitset<N>& rhs) noexcept;
```

3 Returns: bitset<N>(lhs) ^= rhs.

```
template<class charT, class traits, size_t N>
```

```
basic_istream<charT, traits>&
operator>>(basic_istream<charT, traits>& is, bitset<N>& x);
```

4 A formatted input function (??).

5 Effects: Extracts up to N characters from is. Stores these characters in a temporary object str of type basic\_string<charT, traits>, then evaluates the expression x = bitset<N>(str). Characters are extracted and stored until any of the following occurs:

- (5.1) — N characters have been extracted and stored;
- (5.2) — end-of-file occurs on the input sequence;
- (5.3) — the next input character is neither is.widen('0') nor is.widen('1') (in which case the input character is not extracted).

6 If no characters are stored in `str`, calls `is.setstate(ios_base::failbit)` (which may throw `ios_base::failure` (??)).

7 *Returns:* `is`.

```
template<class charT, class traits, size_t N>
basic_ostream<charT, traits>&
operator<<(basic_ostream<charT, traits>& os, const bitset<N>& x);
```

8 *Returns:*

```
os << x.template to_string<charT, traits, allocator<charT>>(
    use_facet<ctype<charT>>(os.getloc()).widen('0'),
    use_facet<ctype<charT>>(os.getloc()).widen('1'))
```

(see ??).

## 23.10 Memory

[memory]

### 23.10.1 In general

[memory.general]

<sup>1</sup> This subclause describes the contents of the header `<memory>` (??) and some of the contents of the header `<cstdlib>` (??).

### 23.10.2 Header `<memory>` synopsis

[memory.syn]

<sup>1</sup> The header `<memory>` defines several types and function templates that describe properties of pointers and pointer-like types, manage memory for containers and other template types, destroy objects, and construct multiple objects in uninitialized memory buffers (??–??). The header also defines the templates `unique_ptr`, `shared_ptr`, `weak_ptr`, and various function templates that operate on objects of these types (??).

```
namespace std {
    // ??, pointer traits
    template<class Ptr> struct pointer_traits;
    template<class T> struct pointer_traits<T*>

    // ??, pointer conversion
    template<class Ptr>
        auto to_address(const Ptr& p) noexcept;
    template<class T>
        constexpr T* to_address(T* p) noexcept;

    // ??, pointer safety
    enum class pointer_safety { relaxed, preferred, strict };
    void declare_reachable(void* p);
    template<class T>
        T* undeclare_reachable(T* p);
    void declare_no_pointers(char* p, size_t n);
    void undeclare_no_pointers(char* p, size_t n);
    pointer_safety get_pointer_safety() noexcept;

    // ??, pointer alignment function
    void* align(size_t alignment, size_t size, void*& ptr, size_t& space);
```

```

// ??, allocator argument tag
struct allocator_arg_t { explicit allocator_arg_t() = default; };
inline constexpr allocator_arg_t allocator_arg{};

// ??, uses_allocator
template<class T, class Alloc> struct uses_allocator;

// ??, allocator traits
template<class Alloc> struct allocator_traits;

// ??, the default allocator
template<class T> class allocator;
template<class T, class U>
    bool operator==(const allocator<T>&, const allocator<U>&) noexcept;
template<class T, class U>
    bool operator!=(const allocator<T>&, const allocator<U>&) noexcept;

// ??, specialized algorithms
template<class T>
    constexpr T* addressof(T& r) noexcept;
template<class T>
    const T* addressof(const T&&) = delete;
template<class ForwardIterator>
    void uninitialized_default_construct(ForwardIterator first, ForwardIterator last);
template<class ExecutionPolicy, class ForwardIterator>
    void uninitialized_default_construct(ExecutionPolicy&& exec, // see ??
                                         ForwardIterator first, ForwardIterator last);
template<class ForwardIterator, class Size>
    ForwardIterator uninitialized_default_construct_n(ForwardIterator first, Size n);
template<class ExecutionPolicy, class ForwardIterator, class Size>
    ForwardIterator uninitialized_default_construct_n(ExecutionPolicy&& exec, // see ??
                                         ForwardIterator first, Size n);
template<class ForwardIterator>
    void uninitialized_value_construct(ForwardIterator first, ForwardIterator last);
template<class ExecutionPolicy, class ForwardIterator>
    void uninitialized_value_construct(ExecutionPolicy&& exec, // see ??
                                         ForwardIterator first, ForwardIterator last);
template<class ForwardIterator, class Size>
    ForwardIterator uninitialized_value_construct_n(ForwardIterator first, Size n);
template<class ExecutionPolicy, class ForwardIterator, class Size>
    ForwardIterator uninitialized_value_construct_n(ExecutionPolicy&& exec, // see ??
                                         ForwardIterator first, Size n);
template<class InputIterator, class ForwardIterator>
    ForwardIterator uninitialized_copy(InputIterator first, InputIterator last,

```

### 23.10.3 Pointer traits

[pointer.traits]

- 1 The class template `pointer_traits` supplies a uniform interface to certain attributes of pointer-like types.

```
namespace std {
    template<class Ptr> struct pointer_traits {
        using pointer      = Ptr;
        using element_type = see below;
        using difference_type = see below;

        template<class U> using rebind = see below;

        static pointer pointer_to(see below r);
    };

    template<class T> struct pointer_traits<T*> {
        using pointer      = T*;
        using element_type = T;
        using difference_type = ptrdiff_t;

        template<class U> using rebind = U*;

        static pointer pointer_to(see below r) noexcept;
    };
}
```

#### 23.10.3.1 Pointer traits member types

[pointer.traits.types]

```
using element_type = see below;
```

- 1 *Type:* `Ptr::element_type` if the *qualified-id* `Ptr::element_type` is valid and denotes a type (??); otherwise, `T` if `Ptr` is a class template instantiation of the form `SomePointer<T, Args>`, where `Args` is

zero or more type arguments; otherwise, the specialization is ill-formed.

```
using difference_type = see below;

2   Type: Ptr::difference_type if the qualified-id Ptr::difference_type is valid and denotes a type
        (??); otherwise, ptrdiff_t.

template<class U> using rebind = see below;

3   Alias template: Ptr::rebind<U> if the qualified-id Ptr::rebind<U> is valid and denotes a type (??);
        otherwise, SomePointer<U, Args> if Ptr is a class template instantiation of the form SomePointer<T,
        Args>, where Args is zero or more type arguments; otherwise, the instantiation of rebind is ill-formed.
```

### 23.10.3.2 Pointer traits member functions

[pointer.traits.functions]

```
static pointer pointer_traits::pointer_to(see below r);
static pointer pointer_traits<T*>::pointer_to(see below r) noexcept;
```

- 1 *Remarks:* If element\_type is cv void, the type of r is unspecified; otherwise, it is element\_type&.
- 2 *Returns:* The first member function returns a pointer to r obtained by calling Ptr::pointer\_to(r) through which indirection is valid; an instantiation of this function is ill-formed if Ptr does not have a matching pointer\_to static member function. The second member function returns addressof(r).

### 23.10.3.3 Pointer traits optional members

[pointer.traits.optmem]

- 1 Specializations of pointer\_traits may define the member declared in this subclause to customize the behavior of the standard library.

```
static element_type* to_address(pointer p) noexcept;
```

- 2 *Returns:* A pointer of type element\_type\* that references the same location as the argument p.
- 3 [Note: This function should be the inverse of pointer\_to. If defined, it customizes the behavior of the non-member function to\_address (??). —end note]

### 23.10.4 Pointer conversion

[pointer.conversion]

```
template<class Ptr> auto to_address(const Ptr& p) noexcept;
```

- 1 *Returns:* pointer\_traits<Ptr>::to\_address(p) if that expression is well-formed (see ??), otherwise to\_address(p.operator->()).

```
template<class T> constexpr T* to_address(T* p) noexcept;
```

- 2 *Requires:* T is not a function type. Otherwise the program is ill-formed.
- 3 *Returns:* p.

### 23.10.5 Pointer safety

[util.dynamic.safety]

- 1 A complete object is declared reachable while the number of calls to declare\_reachable with an argument referencing the object exceeds the number of calls to undeclare\_reachable with an argument referencing the object.

```
void declare_reachable(void* p);
```

- 2 *Requires:* p shall be a safely-derived pointer (??) or a null pointer value.
- 3 *Effects:* If p is not null, the complete object referenced by p is subsequently declared reachable (??).

4       *Throws:* May throw `bad_alloc` if the system cannot allocate additional memory that may be required  
to track objects declared reachable.

```
template<class T> T* undeclare_reachable(T* p);
```

5       *Requires:* If `p` is not null, the complete object referenced by `p` shall have been previously declared  
reachable, and shall be live (??) from the time of the call until the last `undeclare_reachable(p)` call  
on the object.

6       *Returns:* A safely derived copy of `p` which shall compare equal to `p`.

7       *Throws:* Nothing.

8       [*Note:* It is expected that calls to `declare_reachable(p)` will consume a small amount of memory in  
addition to that occupied by the referenced object until the matching call to `undeclare_reachable(p)`  
is encountered. Long running programs should arrange that calls are matched. — *end note*]

```
void declare_no_pointers(char* p, size_t n);
```

9       *Requires:* No bytes in the specified range are currently registered with `declare_no_pointers()`. If  
the specified range is in an allocated object, then it shall be entirely within a single allocated object.  
The object shall be live until the corresponding `undeclare_no_pointers()` call. [*Note:* In a garbage-  
collecting implementation, the fact that a region in an object is registered with `declare_no_pointers()`  
should not prevent the object from being collected. — *end note*]

10      *Effects:* The `n` bytes starting at `p` no longer contain traceable pointer locations, independent of their  
type. Hence indirection through a pointer located there is undefined if the object it points to was  
created by global `operator new` and not previously declared reachable. [*Note:* This may be used to  
inform a garbage collector or leak detector that this region of memory need not be traced. — *end  
note*]

11      *Throws:* Nothing.

12      [*Note:* Under some conditions implementations may need to allocate memory. However, the request  
can be ignored if memory allocation fails. — *end note*]

```
void undeclare_no_pointers(char* p, size_t n);
```

13      *Requires:* The same range shall previously have been passed to `declare_no_pointers()`.

14      *Effects:* Unregisters a range registered with `declare_no_pointers()` for destruction. It shall be called  
before the lifetime of the object ends.

15      *Throws:* Nothing.

```
pointer_safety get_pointer_safety() noexcept;
```

16      *Returns:* `pointer_safety::strict` if the implementation has strict pointer safety (??). It is implementation-  
defined whether `get_pointer_safety` returns `pointer_safety::relaxed` or `pointer_safety::preferred`  
if the implementation has relaxed pointer safety.<sup>226</sup>

### 23.10.6 Align

[`ptr.align`]

```
void* align(size_t alignment, size_t size, void*& ptr, size_t& space);
```

1       *Effects:* If it is possible to fit `size` bytes of storage aligned by `alignment` into the buffer pointed to by

---

<sup>226</sup>) `pointer_safety::preferred` might be returned to indicate that a leak detector is running so that the program can avoid  
spurious leak reports.

`ptr` with length `space`, the function updates `ptr` to represent the first possible address of such storage and decreases `space` by the number of bytes used for alignment. Otherwise, the function does nothing.

2     *Requires:*

- (2.1) — `alignment` shall be a power of two
- (2.2) — `ptr` shall represent the address of contiguous storage of at least `space` bytes

3     *Returns:* A null pointer if the requested aligned buffer would not fit into the available space, otherwise the adjusted value of `ptr`.

4     [*Note:* The function updates its `ptr` and `space` arguments so that it can be called repeatedly with possibly different `alignment` and `size` arguments for the same buffer. — *end note*] ]

### 23.10.7 Allocator argument tag

[allocator.tag]

```
namespace std {
    struct allocator_arg_t { explicit allocator_arg_t() = default; };
    inline constexpr allocator_arg_t allocator_arg{};
}
```

1     The `allocator_arg_t` struct is an empty structure type used as a unique type to disambiguate constructor and function overloading. Specifically, several types (see `tuple ??`) have constructors with `allocator_arg_t` as the first argument, immediately followed by an argument of a type that satisfies the `Allocator` requirements (??).

### 23.10.8 uses\_allocator

[allocator.uses]

#### 23.10.8.1 uses\_allocator trait

[allocator.uses.trait]

```
template<class T, class Alloc> struct uses_allocator;
```

1     *Remarks:* Automatically detects whether `T` has a nested `allocator_type` that is convertible from `Alloc`. Meets the `BinaryTypeTrait` requirements (??). The implementation shall provide a definition that is derived from `true_type` if the *qualified-id* `T::allocator_type` is valid and denotes a type (??) and `is_convertible_v<Alloc, T::allocator_type> != false`, otherwise it shall be derived from `false_type`. A program may specialize this template to derive from `true_type` for a user-defined type `T` that does not have a nested `allocator_type` but nonetheless can be constructed with an allocator where either:

- (1.1) — the first argument of a constructor has type `allocator_arg_t` and the second argument has type `Alloc` or
- (1.2) — the last argument of a constructor has type `Alloc`.

#### 23.10.8.2 Uses-allocator construction

[allocator.uses.construction]

1     *Uses-allocator construction* with allocator `Alloc` refers to the construction of an object `obj` of type `T`, using constructor arguments `v1, v2, ..., vN` of types `V1, V2, ..., VN`, respectively, and an allocator `alloc` of type `Alloc`, according to the following rules:

- (1.1) — if `uses_allocator_v<T, Alloc>` is `false` and `is_constructible_v<T, V1, V2, ..., VN>` is `true`, then `obj` is initialized as `obj(v1, v2, ..., vN)`;
- (1.2) — otherwise, if `uses_allocator_v<T, Alloc>` is `true` and `is_constructible_v<T, allocator_arg_t, Alloc, V1, V2, ..., VN>` is `true`, then `obj` is initialized as `obj(allocator_arg, alloc, v1, v2, ..., vN)`;

- (1.3) — otherwise, if `uses_allocator_v<T, Alloc>` is `true` and `is_constructible_v<T, V1, V2, ..., VN, Alloc>` is `true`, then `obj` is initialized as `obj(v1, v2, ..., vN, alloc);`
- (1.4) — otherwise, the request for uses-allocator construction is ill-formed. [ *Note:* An error will result if `uses_allocator_v<T, Alloc>` is `true` but the specific constructor does not take an allocator. This definition prevents a silent failure to pass the allocator to an element. — *end note* ]

### 23.10.9 Allocator traits

[`allocator_traits`]

- <sup>1</sup> The class template `allocator_traits` supplies a uniform interface to all allocator types. An allocator cannot be a non-class type, however, even if `allocator_traits` supplies the entire required interface. [ *Note:* Thus, it is always possible to create a derived class from an allocator. — *end note* ]

```
namespace std {
    template<class Alloc> struct allocator_traits {
        using allocator_type      = Alloc;
        using value_type          = typename Alloc::value_type;
        using pointer              = see below;
        using const_pointer        = see below;
        using void_pointer         = see below;
        using const_void_pointer   = see below;
        using difference_type     = see below;
        using size_type            = see below;
        using propagate_on_container_copy_assignment = see below;
        using propagate_on_container_move_assignment = see below;
        using propagate_on_container_swap           = see below;
        using is_always_equal                 = see below;
        template<class T> using rebind_alloc = see below;
        template<class T> using rebind_traits = allocator_traits<rebind_alloc<T>>;
        [[nodiscard]] static pointer allocate(Alloc& a, size_type n);
        [[nodiscard]] static pointer allocate(Alloc& a, size_type n, const_void_pointer hint);
        static void deallocate(Alloc& a, pointer p, size_type n);
        template<class T, class... Args>
        static void construct(Alloc& a, T* p, Args&&... args);
        template<class T>
        static void destroy(Alloc& a, T* p);
        static size_type max_size(const Alloc& a) noexcept;
        static Alloc select_on_container_copy_construction(const Alloc& rhs);
    };
}
```

## 23.10.9.1 Allocator traits member types

[allocator.traits.types]

```
using pointer = see below;
```

1     *Type*: `Alloc::pointer` if the *qualified-id* `Alloc::pointer` is valid and denotes a type (??); otherwise, `value_type*`.

```
using const_pointer = see below;
```

2     *Type*: `Alloc::const_pointer` if the *qualified-id* `Alloc::const_pointer` is valid and denotes a type (??); otherwise, `pointer_traits<pointer>::rebind<const value_type>`.

```
using void_pointer = see below;
```

3     *Type*: `Alloc::void_pointer` if the *qualified-id* `Alloc::void_pointer` is valid and denotes a type (??); otherwise, `pointer_traits<pointer>::rebind<void>`.

```
using const_void_pointer = see below;
```

4     *Type*: `Alloc::const_void_pointer` if the *qualified-id* `Alloc::const_void_pointer` is valid and denotes a type (??); otherwise, `pointer_traits<pointer>::rebind<const void>`.

```
using difference_type = see below;
```

5     *Type*: `Alloc::difference_type` if the *qualified-id* `Alloc::difference_type` is valid and denotes a type (??); otherwise, `pointer_traits<pointer>::difference_type`.

```
using size_type = see below;
```

6     *Type*: `Alloc::size_type` if the *qualified-id* `Alloc::size_type` is valid and denotes a type (??); otherwise, `make_unsigned_t<difference_type>`.

```
using propagate_on_container_copy_assignment = see below;
```

7     *Type*: `Alloc::propagate_on_container_copy_assignment` if the *qualified-id* `Alloc::propagate_on_container_copy_assignment` is valid and denotes a type (??); otherwise `false_type`.

```
using propagate_on_container_move_assignment = see below;
```

8     *Type*: `Alloc::propagate_on_container_move_assignment` if the *qualified-id* `Alloc::propagate_on_container_move_assignment` is valid and denotes a type (??); otherwise `false_type`.

```
using propagate_on_container_swap = see below;
```

9     *Type*: `Alloc::propagate_on_container_swap` if the *qualified-id* `Alloc::propagate_on_container_swap` is valid and denotes a type (??); otherwise `false_type`.

```
using is_always_equal = see below;
```

10    *Type*: `Alloc::is_always_equal` if the *qualified-id* `Alloc::is_always_equal` is valid and denotes a type (??); otherwise `is_empty<Alloc>::type`.

```
template<class T> using rebind_alloc = see below;
```

11    *Alias template*: `Alloc::rebind<T>::other` if the *qualified-id* `Alloc::rebind<T>::other` is valid and denotes a type (??); otherwise, `Alloc<T, Args>` if `Alloc` is a class template instantiation of the form `Alloc<U, Args>`, where `Args` is zero or more type arguments; otherwise, the instantiation of `rebind_alloc` is ill-formed.

**23.10.9.2 Allocator traits static member functions**

[allocator.traits.members]

```

[[nodiscard]] static pointer allocate(Alloc& a, size_type n);

1   Returns: a.allocate(n).

[[nodiscard]] static pointer allocate(Alloc& a, size_type n, const_void_pointer hint);

2   Returns: a.allocate(n, hint) if that expression is well-formed; otherwise, a.allocate(n).

static void deallocate(Alloc& a, pointer p, size_type n);

3   Effects: Calls a.deallocate(p, n).

4   Throws: Nothing.

template<class T, class... Args>
static void construct(Alloc& a, T* p, Args&&... args);

5   Effects: Calls a.construct(p, std::forward<Args>(args)... ) if that call is well-formed; otherwise,
invokes ::new (static_cast<void*>(p)) T(std::forward<Args>(args)...).

template<class T>
static void destroy(Alloc& a, T* p);

6   Effects: Calls a.destroy(p) if that call is well-formed; otherwise, invokes p->~T().

static size_type max_size(const Alloc& a) noexcept;

7   Returns: a.max_size() if that expression is well-formed; otherwise, numeric_limits<size_type>::
max()/sizeof(value_type).

static Alloc select_on_container_copy_construction(const Alloc& rhs);

8   Returns: rhs.select_on_container_copy_construction() if that expression is well-formed; otherwise, rhs.

```

**23.10.10 The default allocator**

[default.allocator]

- <sup>1</sup> All specializations of the default allocator satisfy the allocator completeness requirements (??).

```

namespace std {
    template<class T> class allocator {
        public:
            using value_type      = T;
            using propagate_on_container_move_assignment = true_type;
            using is_always_equal = true_type;

            allocator() noexcept;
            allocator(const allocator&) noexcept;
            template<class U> allocator(const allocator<U>&) noexcept;
            ~allocator();

            [[nodiscard]] T* allocate(size_t n);
            void deallocate(T* p, size_t n);
    };
}

```

**23.10.10.1 allocator members**

[allocator.members]

- <sup>1</sup> Except for the destructor, member functions of the default allocator shall not introduce data races (??) as a result of concurrent calls to those member functions from different threads. Calls to these functions that allocate or deallocate a particular unit of storage shall occur in a single total order, and each such deallocation call shall happen before the next allocation (if any) in this order.

`[[nodiscard]] T* allocate(size_t n);`

- <sup>2</sup> *Returns:* A pointer to the initial element of an array of storage of size `n * sizeof(T)`, aligned appropriately for objects of type `T`.

- <sup>3</sup> *Remarks:* the storage is obtained by calling `::operator new (??)`, but it is unspecified when or how often this function is called.

- <sup>4</sup> *Throws:* `bad_alloc` if the storage cannot be obtained.

`void deallocate(T* p, size_t n);`

- <sup>5</sup> *Requires:* `p` shall be a pointer value obtained from `allocate()`. `n` shall equal the value passed as the first argument to the invocation of `allocate` which returned `p`.

- <sup>6</sup> *Effects:* Deallocates the storage referenced by `p`.

- <sup>7</sup> *Remarks:* Uses `::operator delete (??)`, but it is unspecified when this function is called.

**23.10.10.2 allocator globals**

[allocator.globals]

```
template<class T, class U>
bool operator==(const allocator<T>&, const allocator<U>&) noexcept;
```

- <sup>1</sup> *Returns:* true.

```
template<class T, class U>
bool operator!=(const allocator<T>&, const allocator<U>&) noexcept;
```

- <sup>2</sup> *Returns:* false.

**23.10.11 Specialized algorithms**

[specialized.algorithms]

- <sup>1</sup> Throughout this subclause, the names of template parameters are used to express type requirements.

- (1.1) — If an algorithm's template parameter is named `InputIterator`, the template argument shall satisfy the requirements of an input iterator (??).
- (1.2) — If an algorithm's template parameter is named `ForwardIterator`, the template argument shall satisfy the requirements of a forward iterator (??), and is required to have the property that no exceptions are thrown from increment, assignment, comparison, or indirection through valid iterators.

Unless otherwise specified, if an exception is thrown in the following algorithms there are no effects.

**23.10.11.1 addressof**

[specialized.addressof]

```
template<class T> constexpr T* addressof(T& r) noexcept;
```

- <sup>1</sup> *Returns:* The actual address of the object or function referenced by `r`, even in the presence of an overloaded `operator&`.

- <sup>2</sup> *Remarks:* An expression `addressof(E)` is a constant subexpression (??) if `E` is an lvalue constant subexpression.

### 23.10.11.2 uninitialized\_default\_construct [uninitialized.construct.default]

```
template<class ForwardIterator>
void uninitialized_default_construct(ForwardIterator first, ForwardIterator last);
```

1 *Effects:* Equivalent to:

```
for ( ; first != last; ++first)
    ::new (static_cast<void*>(addressof(*first)))
        typename iterator_traits<ForwardIterator>::value_type;
```

```
template<class ForwardIterator, class Size>
ForwardIterator uninitialized_default_construct_n(ForwardIterator first, Size n);
```

2 *Effects:* Equivalent to:

```
for ( ; n > 0; (void)++first, --n)
    ::new (static_cast<void*>(addressof(*first)))
        typename iterator_traits<ForwardIterator>::value_type;
    return first;
```

### 23.10.11.3 uninitialized\_value\_construct [uninitialized.construct.value]

```
template<class ForwardIterator>
void uninitialized_value_construct(ForwardIterator first, ForwardIterator last);
```

1 *Effects:* Equivalent to:

```
for ( ; first != last; ++first)
    ::new (static_cast<void*>(addressof(*first)))
        typename iterator_traits<ForwardIterator>::value_type();
```

```
template<class ForwardIterator, class Size>
ForwardIterator uninitialized_value_construct_n(ForwardIterator first, Size n);
```

2 *Effects:* Equivalent to:

```
for ( ; n > 0; (void)++first, --n)
    ::new (static_cast<void*>(addressof(*first)))
        typename iterator_traits<ForwardIterator>::value_type();
    return first;
```

### 23.10.11.4 uninitialized\_copy [uninitialized.copy]

```
template<class InputIterator, class ForwardIterator>
ForwardIterator uninitialized_copy(InputIterator first, InputIterator last,
                                    ForwardIterator result);
```

1 *Effects:* As if by:

```
for ( ; first != last; ++result, (void) ++first)
    ::new (static_cast<void*>(addressof(*result)))
        typename iterator_traits<ForwardIterator>::value_type(*first);
```

2 *Returns:* result.

```
template<class InputIterator, class Size, class ForwardIterator>
ForwardIterator uninitialized_copy_n(InputIterator first, Size n, ForwardIterator result);
```

3 *Effects:* As if by:

```

    for ( ; n > 0; ++result, (void) ++first, --n) {
        ::new (static_cast<void*>(addressof(*result)))
            typename iterator_traits<ForwardIterator>::value_type(*first);
    }
}

```

4     *Returns:* result.

#### 23.10.11.5 uninitialized\_move

[uninitialized.move]

```

template<class InputIterator, class ForwardIterator>
ForwardIterator uninitialized_move(InputIterator first, InputIterator last,
                                    ForwardIterator result);

```

1     *Effects:* Equivalent to:

```

for ( ; first != last; (void)++result, ++first)
    ::new (static_cast<void*>(addressof(*result)))
        typename iterator_traits<ForwardIterator>::value_type(std::move(*first));
return result;

```

2     *Remarks:* If an exception is thrown, some objects in the range [first, last) are left in a valid but unspecified state.

```

template<class InputIterator, class Size, class ForwardIterator>
pair<InputIterator, ForwardIterator>
uninitialized_move_n(InputIterator first, Size n, ForwardIterator result);

```

3     *Effects:* Equivalent to:

```

for ( ; n > 0; ++result, (void) ++first, --n)
    ::new (static_cast<void*>(addressof(*result)))
        typename iterator_traits<ForwardIterator>::value_type(std::move(*first));
return {first,result};

```

4     *Remarks:* If an exception is thrown, some objects in the range [first, std::next(first,n)) are left in a valid but unspecified state.

#### 23.10.11.6 uninitialized\_fill

[uninitialized.fill]

```

template<class ForwardIterator, class T>
void uninitialized_fill(ForwardIterator first, ForwardIterator last, const T& x);

```

1     *Effects:* As if by:

```

for ( ; first != last; ++first)
    ::new (static_cast<void*>(addressof(*first)))
        typename iterator_traits<ForwardIterator>::value_type(x);

```

```

template<class ForwardIterator, class Size, class T>
ForwardIterator uninitialized_fill_n(ForwardIterator first, Size n, const T& x);

```

2     *Effects:* As if by:

```

for ( ; n--; ++first)
    ::new (static_cast<void*>(addressof(*first)))
        typename iterator_traits<ForwardIterator>::value_type(x);
return first;

```

**23.10.11.7 `destroy`**[**specialized.destroy**]

```
template<class T>
void destroy_at(T* location);

1   Effects: Equivalent to:
      location->~T();

template<class ForwardIterator>
void destroy(ForwardIterator first, ForwardIterator last);

2   Effects: Equivalent to:
      for (; first!=last; ++first)
          destroy_at(addressof(*first));

template<class ForwardIterator, class Size>
ForwardIterator destroy_n(ForwardIterator first, Size n);

3   Effects: Equivalent to:
      for (; n > 0; (void)++first, --n)
          destroy_at(addressof(*first));
      return first;
```

**23.10.12 C library memory allocation**[**c.malloc**]

1 [Note: The header `<cstdlib>` (??) declares the functions described in this subclause. —end note]

```
void* aligned_alloc(size_t alignment, size_t size);
void* calloc(size_t nmemb, size_t size);
void* malloc(size_t size);
void* realloc(void* ptr, size_t size);
```

2 Effects: These functions have the semantics specified in the C standard library.

3 Remarks: These functions do not attempt to allocate storage by calling `::operator new()` (??).

4 Storage allocated directly with these functions is implicitly declared reachable (see ??) on allocation, ceases to be declared reachable on deallocation, and need not cease to be declared reachable as the result of an `undeclare_reachable()` call. [Note: This allows existing C libraries to remain unaffected by restrictions on pointers that are not safely derived, at the expense of providing far fewer garbage collection and leak detection options for `malloc()`-allocated objects. It also allows `malloc()` to be implemented with a separate allocation arena, bypassing the normal `declare_reachable()` implementation. The above functions should never intentionally be used as a replacement for `declare_reachable()`, and newly written code is strongly encouraged to treat memory allocated with these functions as though it were allocated with `operator new`. —end note]

```
void free(void* ptr);
```

5 Effects: This function has the semantics specified in the C standard library.

6 Remarks: This function does not attempt to deallocate storage by calling `::operator delete()`.

SEE ALSO: ISO C 7.22.3

## 23.11 Smart pointers

[smartptr]

### 23.11.1 Class template `unique_ptr`

[unique.ptr]

- <sup>1</sup> A *unique pointer* is an object that owns another object and manages that other object through a pointer. More precisely, a unique pointer is an object *u* that stores a pointer to a second object *p* and will dispose of *p* when *u* is itself destroyed (e.g., when leaving block scope (??)). In this context, *u* is said to *own* *p*.
- <sup>2</sup> The mechanism by which *u* disposes of *p* is known as *p*'s associated *deleter*, a function object whose correct invocation results in *p*'s appropriate disposition (typically its deletion).
- <sup>3</sup> Let the notation *u.p* denote the pointer stored by *u*, and let *u.d* denote the associated deleter. Upon request, *u* can *reset* (replace) *u.p* and *u.d* with another pointer and deleter, but properly disposes of its owned object via the associated deleter before such replacement is considered completed.
- <sup>4</sup> Additionally, *u* can, upon request, *transfer ownership* to another unique pointer *u2*. Upon completion of such a transfer, the following postconditions hold:
  - (4.1) — *u2.p* is equal to the pre-transfer *u.p*,
  - (4.2) — *u.p* is equal to `nullptr`, and
  - (4.3) — if the pre-transfer *u.d* maintained state, such state has been transferred to *u2.d*.

As in the case of a reset, *u2* properly disposes of its pre-transfer owned object via the pre-transfer associated deleter before the ownership transfer is considered complete. [Note: A deleter's state need never be copied, only moved or swapped as ownership is transferred. —end note]

- <sup>5</sup> Each object of a type *U* instantiated from the `unique_ptr` template specified in this subclause has the strict ownership semantics, specified above, of a unique pointer. In partial satisfaction of these semantics, each such *U* is `MoveConstructible` and `MoveAssignable`, but is not `CopyConstructible` nor `CopyAssignable`. The template parameter *T* of `unique_ptr` may be an incomplete type.
- <sup>6</sup> [Note: The uses of `unique_ptr` include providing exception safety for dynamically allocated memory, passing ownership of dynamically allocated memory to a function, and returning dynamically allocated memory from a function. —end note]

#### 23.11.1.1 Default deleters

[unique.ptr.dltr]

##### 23.11.1.1.1 In general

[unique.ptr.dltr.general]

- <sup>1</sup> The class template `default_delete` serves as the default deleter (destruction policy) for the class template `unique_ptr`.
- <sup>2</sup> The template parameter *T* of `default_delete` may be an incomplete type.

##### 23.11.1.1.2 `default_delete`

[unique.ptr.dltr.dflt]

```
namespace std {
    template<class T> struct default_delete {
        constexpr default_delete() noexcept = default;
        template<class U> default_delete(const default_delete<U>&) noexcept;
        void operator()(T*) const;
    };
}

template<class U> default_delete(const default_delete<U>& other) noexcept;
```

<sup>1</sup> Effects: Constructs a `default_delete` object from another `default_delete<U>` object.

2       *Remarks:* This constructor shall not participate in overload resolution unless U\* is implicitly convertible to T\*.

void operator()(T\* ptr) const;

3       *Effects:* Calls `delete` on `ptr`.

4       *Remarks:* If T is an incomplete type, the program is ill-formed.

### 23.11.1.3 default\_delete<T[]>

[unique.ptr.dltr.dflt1]

```
namespace std {
    template<class T> struct default_delete<T[]> {
        constexpr default_delete() noexcept = default;
        template<class U> default_delete(const default_delete<U[]>&) noexcept;
        template<class U> void operator()(U* ptr) const;
    };
}
```

template<class U> default\_delete(const default\_delete<U[]>& other) noexcept;

1       *Effects:* Constructs a `default_delete` object from another `default_delete<U[]>` object.

2       *Remarks:* This constructor shall not participate in overload resolution unless `U(*)[]` is convertible to `T(*)[]`.

template<class U> void operator()(U\* ptr) const;

3       *Effects:* Calls `delete[]` on `ptr`.

4       *Remarks:* If U is an incomplete type, the program is ill-formed. This function shall not participate in overload resolution unless `U(*)[]` is convertible to `T(*)[]`.

### 23.11.1.2 unique\_ptr for single objects

[unique.ptr.single]

```
namespace std {
    template<class T, class D = default_delete<T>> class unique_ptr {
    public:
        using pointer      = see below;
        using element_type = T;
        using deleter_type = D;

        // ??, constructors
        constexpr unique_ptr() noexcept;
        explicit unique_ptr(pointer p) noexcept;
        unique_ptr(pointer p, see below d1) noexcept;
        unique_ptr(pointer p, see below d2) noexcept;
        unique_ptr(unique_ptr&& u) noexcept;
        constexpr unique_ptr(nullptr_t) noexcept;
        template<class U, class E>
            unique_ptr(unique_ptr<U, E>&& u) noexcept;

        // ??, destructor
        ~unique_ptr();
    };
}
```

```

// ??, assignment
unique_ptr& operator=(unique_ptr&& u) noexcept;
template<class U, class E>
    unique_ptr& operator=(unique_ptr<U, E>&& u) noexcept;
unique_ptr& operator=(nullptr_t) noexcept;

// ??, observers
add_lvalue_reference_t<T> operator*() const;
pointer operator->() const noexcept;
pointer get() const noexcept;
deleter_type& get_deleter() noexcept;
const deleter_type& get_deleter() const noexcept;
explicit operator bool() const noexcept;

// ??, modifiers
pointer release() noexcept;
void reset(pointer p = pointer()) noexcept;
void swap(unique_ptr& u) noexcept;

// disable copy from lvalue
unique_ptr(const unique_ptr&) = delete;
unique_ptr& operator=(const unique_ptr&) = delete;
};

}

```

- <sup>1</sup> The default type for the template parameter D is `default_delete`. A client-supplied template argument D shall be a function object type (??), lvalue reference to function, or lvalue reference to function object type for which, given a value d of type D and a value ptr of type `unique_ptr<T, D>::pointer`, the expression `d(ptr)` is valid and has the effect of disposing of the pointer as appropriate for that deleter.
- <sup>2</sup> If the deleter's type D is not a reference type, D shall satisfy the requirements of `Destructible` (Table ??).
- <sup>3</sup> If the `qualified-id remove_reference_t<D>::pointer` is valid and denotes a type (??), then `unique_ptr<T, D>::pointer` shall be a synonym for `remove_reference_t<D>::pointer`. Otherwise `unique_ptr<T, D>::pointer` shall be a synonym for `element_type*`. The type `unique_ptr<T, D>::pointer` shall satisfy the requirements of `NullablePointer` (??).
- <sup>4</sup> [Example: Given an allocator type X (??) and letting A be a synonym for `allocator_traits<X>`, the types `A::pointer`, `A::const_pointer`, `A::void_pointer`, and `A::const_void_pointer` may be used as `unique_ptr<T, D>::pointer`. —end example]

### 23.11.1.2.1 unique\_ptr constructors

[`unique.ptr.single.ctor`]

```
constexpr unique_ptr() noexcept;
constexpr unique_ptr(nullptr_t) noexcept;
```

- <sup>1</sup> *Requires:* D shall satisfy the requirements of `DefaultConstructible` (Table ??), and that construction shall not throw an exception.
- <sup>2</sup> *Effects:* Constructs a `unique_ptr` object that owns nothing, value-initializing the stored pointer and the stored deleter.
- <sup>3</sup> *Postconditions:* `get() == nullptr`. `get_deleter()` returns a reference to the stored deleter.

4     *Remarks:* If `is_pointer_v<deleter_type>` is `true` or `is_default_constructible_v<deleter_type>` is `false`, this constructor shall not participate in overload resolution.

```
explicit unique_ptr(pointer p) noexcept;
```

5     *Requires:* D shall satisfy the requirements of `DefaultConstructible` (Table ??), and that construction shall not throw an exception.

6     *Effects:* Constructs a `unique_ptr` which owns p, initializing the stored pointer with p and value-initializing the stored deleter.

7     *Postconditions:* `get() == p`. `get_deleter()` returns a reference to the stored deleter.

8     *Remarks:* If `is_pointer_v<deleter_type>` is `true` or `is_default_constructible_v<deleter_type>` is `false`, this constructor shall not participate in overload resolution. If class template argument deduction (??) would select the function template corresponding to this constructor, then the program is ill-formed.

```
unique_ptr(pointer p, see below d1) noexcept;
unique_ptr(pointer p, see below d2) noexcept;
```

9     The signature of these constructors depends upon whether D is a reference type. If D is a non-reference type A, then the signatures are:

```
unique_ptr(pointer p, const A& d) noexcept;
unique_ptr(pointer p, A&& d) noexcept;
```

10    If D is an lvalue reference type A&, then the signatures are:

```
unique_ptr(pointer p, A& d) noexcept;
unique_ptr(pointer p, A&& d) = delete;
```

11    If D is an lvalue reference type const A&, then the signatures are:

```
unique_ptr(pointer p, const A& d) noexcept;
unique_ptr(pointer p, const A&& d) = delete;
```

12    *Requires:* For the first constructor, if D is not a reference type, D shall satisfy the requirements of `CopyConstructible` and such construction shall not exit via an exception. For the second constructor, if D is not a reference type, D shall satisfy the requirements of `MoveConstructible` and such construction shall not exit via an exception.

13    *Effects:* Constructs a `unique_ptr` object which owns p, initializing the stored pointer with p and initializing the deleter from `std::forward<decltype(d)>(d)`.

14    *Remarks:* These constructors shall not participate in overload resolution unless `is_constructible_v<D, decltype(d)>` is `true`.

15    *Postconditions:* `get() == p`. `get_deleter()` returns a reference to the stored deleter. If D is a reference type then `get_deleter()` returns a reference to the lvalue d.

16    *Remarks:* If class template argument deduction (??) would select a function template corresponding to either of these constructors, then the program is ill-formed.

17    [ *Example:*

```
D d;
unique_ptr<int, D> p1(new int, D());           // D must be MoveConstructible
unique_ptr<int, D> p2(new int, d);             // D must be CopyConstructible
unique_ptr<int, D&> p3(new int, d);            // p3 holds a reference to d
```

```
unique_ptr<int, const D&> p4(new int, D()); // error: rvalue deleter object combined
                                                // with reference deleter type
```

— end example ]

```
unique_ptr(unique_ptr&& u) noexcept;
```

18     *Requires:* If D is not a reference type, D shall satisfy the requirements of **MoveConstructible** (Table ??). Construction of the deleter from an rvalue of type D shall not throw an exception.

19     *Effects:* Constructs a **unique\_ptr** by transferring ownership from u to **\*this**. If D is a reference type, this deleter is copy constructed from u's deleter; otherwise, this deleter is move constructed from u's deleter. [ *Note:* The deleter constructor can be implemented with `std::forward<D>`. — end note ]

20     *Postconditions:* `get()` yields the value `u.get()` yielded before the construction. `get_deleter()` returns a reference to the stored deleter that was constructed from `u.get_deleter()`. If D is a reference type then `get_deleter()` and `u.get_deleter()` both reference the same lvalue deleter.

```
template<class U, class E> unique_ptr(unique_ptr<U, E>&& u) noexcept;
```

21     *Requires:* If E is not a reference type, construction of the deleter from an rvalue of type E shall be well-formed and shall not throw an exception. Otherwise, E is a reference type and construction of the deleter from an lvalue of type E shall be well-formed and shall not throw an exception.

22     *Remarks:* This constructor shall not participate in overload resolution unless:

- (22.1) — `unique_ptr<U, E>::pointer` is implicitly convertible to `pointer`,
- (22.2) — U is not an array type, and
- (22.3) — either D is a reference type and E is the same type as D, or D is not a reference type and E is implicitly convertible to D.

23     *Effects:* Constructs a **unique\_ptr** by transferring ownership from u to **\*this**. If E is a reference type, this deleter is copy constructed from u's deleter; otherwise, this deleter is move constructed from u's deleter. [ *Note:* The deleter constructor can be implemented with `std::forward<E>`. — end note ]

24     *Postconditions:* `get()` yields the value `u.get()` yielded before the construction. `get_deleter()` returns a reference to the stored deleter that was constructed from `u.get_deleter()`.

### 23.11.1.2.2 **unique\_ptr** destructor

[**unique.ptr.single.dtor**]

```
~unique_ptr();
```

1     *Requires:* The expression `get_deleter()(get())` shall be well-formed, shall have well-defined behavior, and shall not throw exceptions. [ *Note:* The use of `default_delete` requires T to be a complete type. — end note ]

2     *Effects:* If `get() == nullptr` there are no effects. Otherwise `get_deleter()(get())`.

### 23.11.1.2.3 **unique\_ptr** assignment

[**unique.ptr.single.asgn**]

```
unique_ptr& operator=(unique_ptr&& u) noexcept;
```

1     *Requires:* If D is not a reference type, D shall satisfy the requirements of **MoveAssignable** (Table ??) and assignment of the deleter from an rvalue of type D shall not throw an exception. Otherwise, D is a reference type; `remove_reference_t<D>` shall satisfy the **CopyAssignable** requirements and assignment of the deleter from an lvalue of type D shall not throw an exception.

2       *Effects:* Transfers ownership from *u* to *\*this* as if by calling `reset(u.release())` followed by `get_deleter() = std::forward<D>(u.get_deleter())`.

3       *Returns:* `*this`.

```
template<class U, class E> unique_ptr& operator=(unique_ptr<U, E>&& u) noexcept;
```

4       *Requires:* If *E* is not a reference type, assignment of the deleter from an rvalue of type *E* shall be well-formed and shall not throw an exception. Otherwise, *E* is a reference type and assignment of the deleter from an lvalue of type *E* shall be well-formed and shall not throw an exception.

5       *Remarks:* This operator shall not participate in overload resolution unless:

(5.1)     — `unique_ptr<U, E>::pointer` is implicitly convertible to `pointer`, and

(5.2)     — *U* is not an array type, and

(5.3)     — `is_assignable_v<D&, E&&>` is true.

6       *Effects:* Transfers ownership from *u* to *\*this* as if by calling `reset(u.release())` followed by `get_deleter() = std::forward<E>(u.get_deleter())`.

7       *Returns:* `*this`.

```
unique_ptr& operator=(nullptr_t) noexcept;
```

8       *Effects:* As if by `reset()`.

9       *Postconditions:* `get() == nullptr`.

10      *Returns:* `*this`.

#### 23.11.1.2.4 unique\_ptr observers

[`unique.ptr.single.observers`]

```
add_lvalue_reference_t<T> operator*() const;
```

1       *Requires:* `get() != nullptr`.

2       *Returns:* `*get()`.

```
pointer operator->() const noexcept;
```

3       *Requires:* `get() != nullptr`.

4       *Returns:* `get()`.

5       *[ Note:* The use of this function typically requires that *T* be a complete type. — end note *]*

```
pointer get() const noexcept;
```

6       *Returns:* The stored pointer.

```
deleter_type& get_deleter() noexcept;
const deleter_type& get_deleter() const noexcept;
```

7       *Returns:* A reference to the stored deleter.

```
explicit operator bool() const noexcept;
```

8       *Returns:* `get() != nullptr`.

**23.11.1.2.5 unique\_ptr modifiers**

[unique.ptr.single.modifiers]

```
pointer release() noexcept;
```

1       *Postconditions:* `get() == nullptr`.

2       *Returns:* The value `get()` had at the start of the call to `release`.

```
void reset(pointer p = pointer()) noexcept;
```

3       *Requires:* The expression `get_deleter()(get())` shall be well-formed, shall have well-defined behavior, and shall not throw exceptions.

4       *Effects:* Assigns `p` to the stored pointer, and then if and only if the old value of the stored pointer, `old_p`, was not equal to `nullptr`, calls `get_deleter()(old_p)`. [Note: The order of these operations is significant because the call to `get_deleter()` may destroy `*this`. —end note]

5       *Postconditions:* `get() == p`. [Note: The postcondition does not hold if the call to `get_deleter()` destroys `*this` since `this->get()` is no longer a valid expression. —end note]

```
void swap(unique_ptr& u) noexcept;
```

6       *Requires:* `get_deleter()` shall be swappable (??) and shall not throw an exception under `swap`.

7       *Effects:* Invokes `swap` on the stored pointers and on the stored deleters of `*this` and `u`.

**23.11.1.3 unique\_ptr for array objects with a runtime length**

[unique.ptr.runtime]

```
namespace std {
    template<class T, class D> class unique_ptr<T[], D> {
        public:
            using pointer      = see below;
            using element_type = T;
            using deleter_type = D;

            // ??, constructors
            constexpr unique_ptr() noexcept;
            template<class U> explicit unique_ptr(U p) noexcept;
            template<class U> unique_ptr(U p, see below d) noexcept;
            template<class U> unique_ptr(U p, see below d) noexcept;
            unique_ptr(unique_ptr&& u) noexcept;
            template<class U, class E>
                unique_ptr(unique_ptr<U, E>&& u) noexcept;
            constexpr unique_ptr(nullptr_t) noexcept;

            // destructor
            ~unique_ptr();

            // assignment
            unique_ptr& operator=(unique_ptr&& u) noexcept;
            template<class U, class E>
                unique_ptr& operator=(unique_ptr<U, E>&& u) noexcept;
            unique_ptr& operator=(nullptr_t) noexcept;

            // ??, observers
            T& operator[](size_t i) const;
    };
}
```

```

pointer get() const noexcept;
deleter_type& get_deleter() noexcept;
const deleter_type& get_deleter() const noexcept;
explicit operator bool() const noexcept;

// ??, modifiers
pointer release() noexcept;
template<class U> void reset(U p) noexcept;
void reset(nullptr_t = nullptr) noexcept;
void swap(unique_ptr& u) noexcept;

// disable copy from lvalue
unique_ptr(const unique_ptr&) = delete;
unique_ptr& operator=(const unique_ptr&) = delete;
};

}

```

<sup>1</sup> A specialization for array types is provided with a slightly altered interface.

- (1.1) — Conversions between different types of `unique_ptr<T[] , D>` that would be disallowed for the corresponding pointer-to-array types, and conversions to or from the non-array forms of `unique_ptr`, produce an ill-formed program.
- (1.2) — Pointers to types derived from `T` are rejected by the constructors, and by `reset`.
- (1.3) — The observers `operator*` and `operator->` are not provided.
- (1.4) — The indexing observer `operator[]` is provided.
- (1.5) — The default deleter will call `delete[]`.

<sup>2</sup> Descriptions are provided below only for members that differ from the primary template.

<sup>3</sup> The template argument `T` shall be a complete type.

### 23.11.1.3.1 unique\_ptr constructors

[`unique.ptr.runtime.ctor`]

```
template<class U> explicit unique_ptr(U p) noexcept;
```

- 1 This constructor behaves the same as the constructor in the primary template that takes a single parameter of type `pointer` except that it additionally shall not participate in overload resolution unless
  - (1.1) — `U` is the same type as `pointer`, or
  - (1.2) — `pointer` is the same type as `element_type*`, `U` is a pointer type `V*`, and `V(*)[]` is convertible to `element_type(*)[]`.

```
template<class U> unique_ptr(U p, see below d) noexcept;
template<class U> unique_ptr(U p, see below d) noexcept;
```

- 2 These constructors behave the same as the constructors in the primary template that take a parameter of type `pointer` and a second parameter except that they shall not participate in overload resolution unless either
  - (2.1) — `U` is the same type as `pointer`,
  - (2.2) — `U` is `nullptr_t`, or

- (2.3) — `pointer` is the same type as `element_type*`, `U` is a pointer type `V*`, and `V(*)[]` is convertible to `element_type(*)[]`.

```
template<class U, class E> unique_ptr(unique_ptr<U, E>&& u) noexcept;
```

- 3 This constructor behaves the same as in the primary template, except that it shall not participate in overload resolution unless all of the following conditions hold, where `UP` is `unique_ptr<U, E>`:

- (3.1) — `U` is an array type, and
- (3.2) — `pointer` is the same type as `element_type*`, and
- (3.3) — `UP::pointer` is the same type as `UP::element_type*`, and
- (3.4) — `UP::element_type(*)[]` is convertible to `element_type(*)[]`, and
- (3.5) — either `D` is a reference type and `E` is the same type as `D`, or `D` is not a reference type and `E` is implicitly convertible to `D`.

[*Note:* This replaces the overload-resolution specification of the primary template — *end note*]

### 23.11.1.3.2 unique\_ptr assignment

[`unique.ptr.runtime.asgn`]

```
template<class U, class E> unique_ptr& operator=(unique_ptr<U, E>&& u) noexcept;
```

- 1 This operator behaves the same as in the primary template, except that it shall not participate in overload resolution unless all of the following conditions hold, where `UP` is `unique_ptr<U, E>`:

- (1.1) — `U` is an array type, and
- (1.2) — `pointer` is the same type as `element_type*`, and
- (1.3) — `UP::pointer` is the same type as `UP::element_type*`, and
- (1.4) — `UP::element_type(*)[]` is convertible to `element_type(*)[]`, and
- (1.5) — `is_assignable_v<D&, E&&>` is true.

[*Note:* This replaces the overload-resolution specification of the primary template — *end note*]

### 23.11.1.3.3 unique\_ptr observers

[`unique.ptr.runtime.observers`]

```
T& operator[](size_t i) const;
```

- 1 *Requires:* `i <` the number of elements in the array to which the stored pointer points.

- 2 *Returns:* `get()[i]`.

### 23.11.1.3.4 unique\_ptr modifiers

[`unique.ptr.runtime.modifiers`]

```
void reset(nullptr_t p = nullptr) noexcept;
```

- 1 *Effects:* Equivalent to `reset(pointer())`.

```
template<class U> void reset(U p) noexcept;
```

- 2 This function behaves the same as the `reset` member of the primary template, except that it shall not participate in overload resolution unless either

- (2.1) — `U` is the same type as `pointer`, or
- (2.2) — `pointer` is the same type as `element_type*`, `U` is a pointer type `V*`, and `V(*)[]` is convertible to `element_type(*)[]`.

**23.11.1.4 unique\_ptr creation**

[unique.ptr.create]

```
template<class T, class... Args> unique_ptr<T> make_unique(Args&&... args);
```

1     *Remarks:* This function shall not participate in overload resolution unless T is not an array.

2     *Returns:* unique\_ptr<T>(new T(std::forward<Args>(args)...)).

```
template<class T> unique_ptr<T> make_unique(size_t n);
```

3     *Remarks:* This function shall not participate in overload resolution unless T is an array of unknown bound.

4     *Returns:* unique\_ptr<T>(new remove\_extent\_t<T>[n]()).

```
template<class T, class... Args> unspecified make_unique(Args&&...) = delete;
```

5     *Remarks:* This function shall not participate in overload resolution unless T is an array of known bound.

**23.11.1.5 unique\_ptr specialized algorithms**

[unique.ptr.special]

```
template<class T, class D> void swap(unique_ptr<T, D>& x, unique_ptr<T, D>& y) noexcept;
```

1     *Remarks:* This function shall not participate in overload resolution unless `is_swappable_v<D>` is `true`.

2     *Effects:* Calls `x.swap(y)`.

```
template<class T1, class D1, class T2, class D2>
bool operator==(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);
```

3     *Returns:* `x.get() == y.get()`.

```
template<class T1, class D1, class T2, class D2>
bool operator!=(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);
```

4     *Returns:* `x.get() != y.get()`.

```
template<class T1, class D1, class T2, class D2>
bool operator<(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);
```

5     *Requires:* Let CT denote

```
common_type_t<typename unique_ptr<T1, D1>::pointer,
              typename unique_ptr<T2, D2>::pointer>
```

Then the specialization `less<CT>` shall be a function object type (??) that induces a strict weak ordering (??) on the pointer values.

6     *Returns:* `less<CT>()(x.get(), y.get())`.

7     *Remarks:* If `unique_ptr<T1, D1>::pointer` is not implicitly convertible to CT or `unique_ptr<T2, D2>::pointer` is not implicitly convertible to CT, the program is ill-formed.

```
template<class T1, class D1, class T2, class D2>
bool operator<=(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);
```

8     *Returns:* `!(y < x)`.

```
template<class T1, class D1, class T2, class D2>
bool operator>(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);
```

9     *Returns:* `y < x`.

```

template<class T1, class D1, class T2, class D2>
bool operator>=(const unique_ptr<T1, D1>& x, const unique_ptr<T2, D2>& y);

10   Returns: !(x < y).

template<class T, class D>
bool operator==(const unique_ptr<T, D>& x, nullptr_t) noexcept;
template<class T, class D>
bool operator==(nullptr_t, const unique_ptr<T, D>& x) noexcept;

11   Returns: !x.

template<class T, class D>
bool operator!=(const unique_ptr<T, D>& x, nullptr_t) noexcept;
template<class T, class D>
bool operator!=(nullptr_t, const unique_ptr<T, D>& x) noexcept;

12   Returns: (bool)x.

template<class T, class D>
bool operator<(const unique_ptr<T, D>& x, nullptr_t);
template<class T, class D>
bool operator<(nullptr_t, const unique_ptr<T, D>& x);

13   Requires: The specialization less<unique_ptr<T, D>::pointer> shall be a function object type (??)
that induces a strict weak ordering (??) on the pointer values.

14   Returns: The first function template returns

    less<unique_ptr<T, D>::pointer>()(x.get(), nullptr)

The second function template returns

    less<unique_ptr<T, D>::pointer>()(nullptr, x.get())

template<class T, class D>
bool operator>(const unique_ptr<T, D>& x, nullptr_t);
template<class T, class D>
bool operator>(nullptr_t, const unique_ptr<T, D>& x);

15   Returns: The first function template returns nullptr < x. The second function template returns x <
nullptr.

template<class T, class D>
bool operator<=(const unique_ptr<T, D>& x, nullptr_t);
template<class T, class D>
bool operator<=(nullptr_t, const unique_ptr<T, D>& x);

16   Returns: The first function template returns !(nullptr < x). The second function template returns
!(x < nullptr).

template<class T, class D>
bool operator>=(const unique_ptr<T, D>& x, nullptr_t);
template<class T, class D>
bool operator>=(nullptr_t, const unique_ptr<T, D>& x);

17   Returns: The first function template returns !(x < nullptr). The second function template returns
!(nullptr < x).

```

### 23.11.1.6 unique\_ptr I/O [unique.ptr.io]

```
template<class E, class T, class Y, class D>
basic_ostream<E, T>& operator<<(basic_ostream<E, T>& os, const unique_ptr<Y, D>& p);
```

<sup>1</sup> *Effects:* Equivalent to: `os << p.get();`

<sup>2</sup> *Returns:* `os`.

<sup>3</sup> *Remarks:* This function shall not participate in overload resolution unless `os << p.get()` is a valid expression.

### 23.11.2 Class bad\_weak\_ptr [util.smartptr.weak.bad]

```
namespace std {
    class bad_weak_ptr : public exception {
        public:
            bad_weak_ptr() noexcept;
    };
}
```

<sup>1</sup> An exception of type `bad_weak_ptr` is thrown by the `shared_ptr` constructor taking a `weak_ptr`.

```
bad_weak_ptr() noexcept;
2 Postconditions: what() returns an implementation-defined NTBS.
```

### 23.11.3 Class template shared\_ptr [util.smartptr.shared]

<sup>1</sup> The `shared_ptr` class template stores a pointer, usually obtained via `new`. `shared_ptr` implements semantics of shared ownership; the last remaining owner of the pointer is responsible for destroying the object, or otherwise releasing the resources associated with the stored pointer. A `shared_ptr` is said to be empty if it does not own a pointer.

```
namespace std {
    template<class T> class shared_ptr {
        public:
            using element_type = remove_extent_t<T>;
            using weak_type = weak_ptr<T>;

            // ??, constructors
            constexpr shared_ptr() noexcept;
            constexpr shared_ptr(nullptr_t) noexcept : shared_ptr() { }
            template<class Y>
                explicit shared_ptr(Y* p);
            template<class Y, class D>
                shared_ptr(Y* p, D d);
            template<class Y, class D, class A>
                shared_ptr(Y* p, D d, A a);
            template<class D>
                shared_ptr(nullptr_t p, D d);
            template<class D, class A>
                shared_ptr(nullptr_t p, D d, A a);
            template<class Y>
                shared_ptr(const shared_ptr<Y>& r, element_type* p) noexcept;
                shared_ptr(const shared_ptr& r) noexcept;
```

```

template<class Y>
    shared_ptr(const shared_ptr<Y>& r) noexcept;
shared_ptr(shared_ptr&& r) noexcept;
template<class Y>
    shared_ptr(shared_ptr<Y>&& r) noexcept;
template<class Y>
    explicit shared_ptr(const weak_ptr<Y>& r);
template<class Y, class D>
    shared_ptr(unique_ptr<Y, D>&& r);

// ??, destructor
~shared_ptr();

// ??, assignment
shared_ptr& operator=(const shared_ptr& r) noexcept;
template<class Y>
    shared_ptr& operator=(const shared_ptr<Y>& r) noexcept;
shared_ptr& operator=(shared_ptr&& r) noexcept;
template<class Y>
    shared_ptr& operator=(shared_ptr<Y>&& r) noexcept;
template<class Y, class D>
    shared_ptr& operator=(unique_ptr<Y, D>&& r);

// ??, modifiers
void swap(shared_ptr& r) noexcept;
void reset() noexcept;
template<class Y>
    void reset(Y* p);
template<class Y, class D>
    void reset(Y* p, D d);
template<class Y, class D, class A>
    void reset(Y* p, D d, A a);

// ??, observers
element_type* get() const noexcept;
T& operator*() const noexcept;
T* operator->() const noexcept;
element_type& operator[](ptrdiff_t i) const;
long use_count() const noexcept;
explicit operator bool() const noexcept;
template<class U>
    bool owner_before(const shared_ptr<U>& b) const noexcept;
template<class U>
    bool owner_before(const weak_ptr<U>& b) const noexcept;
};

template<class T>
    shared_ptr(weak_ptr<T>) -> shared_ptr<T>;

```

```
template<class T, class D>
    shared_ptr(unique_ptr<T, D>) -> shared_ptr<T>;
}
```

- <sup>2</sup> Specializations of `shared_ptr` shall be `CopyConstructible`, `CopyAssignable`, and `LessThanComparable`, allowing their use in standard containers. Specializations of `shared_ptr` shall be contextually convertible to `bool`, allowing their use in boolean expressions and declarations in conditions. The template parameter `T` of `shared_ptr` may be an incomplete type.

- <sup>3</sup> [*Example*:

```
if (shared_ptr<X> px = dynamic_pointer_cast<X>(py)) {
    // do something with px
}
— end example ]
```

- <sup>4</sup> For purposes of determining the presence of a data race, member functions shall access and modify only the `shared_ptr` and `weak_ptr` objects themselves and not objects they refer to. Changes in `use_count()` do not reflect modifications that can introduce data races.
- <sup>5</sup> For the purposes of subclause ??, a pointer type `Y*` is said to be *compatible with* a pointer type `T*` when either `Y*` is convertible to `T*` or `Y` is `U[N]` and `T` is *cv U[]*.

### 23.11.3.1 `shared_ptr` constructors

[`util.smartptr.shared.const`]

- <sup>1</sup> In the constructor definitions below, enables `shared_from_this` with `p`, for a pointer `p` of type `Y*`, means that if `Y` has an unambiguous and accessible base class that is a specialization of `enable_shared_from_this` (??), then `remove_cv_t<Y>*` shall be implicitly convertible to `T*` and the constructor evaluates the statement:

```
if (p != nullptr && p->weak_this.expired())
    p->weak_this = shared_ptr<remove_cv_t<Y>>(*this, const_cast<remove_cv_t<Y>>(p));
```

The assignment to the `weak_this` member is not atomic and conflicts with any potentially concurrent access to the same object (??).

```
constexpr shared_ptr() noexcept;
```

- <sup>2</sup> *Effects*: Constructs an empty `shared_ptr` object.

- <sup>3</sup> *Postconditions*: `use_count() == 0 && get() == nullptr`.

```
template<class Y> explicit shared_ptr(Y* p);
```

- <sup>4</sup> *Requires*: `Y` shall be a complete type. The expression `delete[] p`, when `T` is an array type, or `delete p`, when `T` is not an array type, shall have well-defined behavior, and shall not throw exceptions.

- <sup>5</sup> *Effects*: When `T` is not an array type, constructs a `shared_ptr` object that owns the pointer `p`. Otherwise, constructs a `shared_ptr` that owns `p` and a deleter of an unspecified type that calls `delete[] p`. When `T` is not an array type, enables `shared_from_this` with `p`. If an exception is thrown, `delete p` is called when `T` is not an array type, `delete[] p` otherwise.

- <sup>6</sup> *Postconditions*: `use_count() == 1 && get() == p`.

- <sup>7</sup> *Throws*: `bad_alloc`, or an implementation-defined exception when a resource other than memory could not be obtained.

- <sup>8</sup> *Remarks*: When `T` is an array type, this constructor shall not participate in overload resolution unless the expression `delete[] p` is well-formed and either `T` is `U[N]` and `Y(*)[N]` is convertible to `T*`, or `T` is

`U[]` and `Y(*)[]` is convertible to `T*`. When `T` is not an array type, this constructor shall not participate in overload resolution unless the expression `delete p` is well-formed and `Y*` is convertible to `T*`.

```
template<class Y, class D> shared_ptr(Y* p, D d);
template<class Y, class D, class A> shared_ptr(Y* p, D d, A a);
template<class D> shared_ptr(nullptr_t p, D d);
template<class D, class A> shared_ptr(nullptr_t p, D d, A a);
```

9     *Requires:* Construction of `d` and a deleter of type `D` initialized with `std::move(d)` shall not throw exceptions. The expression `d(p)` shall have well-defined behavior and shall not throw exceptions. `A` shall be an allocator (??).

10    *Effects:* Constructs a `shared_ptr` object that owns the object `p` and the deleter `d`. When `T` is not an array type, the first and second constructors enable `shared_from_this` with `p`. The second and fourth constructors shall use a copy of `a` to allocate memory for internal use. If an exception is thrown, `d(p)` is called.

11    *Postconditions:* `use_count() == 1 && get() == p`.

12    *Throws:* `bad_alloc`, or an implementation-defined exception when a resource other than memory could not be obtained.

13    *Remarks:* When `T` is an array type, this constructor shall not participate in overload resolution unless `is_move_constructible_v<D>` is `true`, the expression `d(p)` is well-formed, and either `T` is `U[N]` and `Y(*)[N]` is convertible to `T*`, or `T` is `U[]` and `Y(*)[]` is convertible to `T*`. When `T` is not an array type, this constructor shall not participate in overload resolution unless `is_move_constructible_v<D>` is `true`, the expression `d(p)` is well-formed, and `Y*` is convertible to `T*`.

```
template<class Y> shared_ptr(const shared_ptr<Y>& r, element_type* p) noexcept;
```

14    *Effects:* Constructs a `shared_ptr` instance that stores `p` and shares ownership with `r`.

15    *Postconditions:* `get() == p && use_count() == r.use_count()`.

16    [*Note:* To avoid the possibility of a dangling pointer, the user of this constructor should ensure that `p` remains valid at least until the ownership group of `r` is destroyed. — *end note*]

17    [*Note:* This constructor allows creation of an empty `shared_ptr` instance with a non-null stored pointer. — *end note*]

```
shared_ptr(const shared_ptr& r) noexcept;
template<class Y> shared_ptr(const shared_ptr<Y>& r) noexcept;
```

18    *Remarks:* The second constructor shall not participate in overload resolution unless `Y*` is compatible with `T*`.

19    *Effects:* If `r` is empty, constructs an empty `shared_ptr` object; otherwise, constructs a `shared_ptr` object that shares ownership with `r`.

20    *Postconditions:* `get() == r.get() && use_count() == r.use_count()`.

```
shared_ptr(shared_ptr&& r) noexcept;
template<class Y> shared_ptr(shared_ptr<Y>&& r) noexcept;
```

21    *Remarks:* The second constructor shall not participate in overload resolution unless `Y*` is compatible with `T*`.

22    *Effects:* Move constructs a `shared_ptr` instance from `r`.

23     *Postconditions:* `*this` shall contain the old value of `r`. `r` shall be empty. `r.get() == nullptr`.

```
template<class Y> explicit shared_ptr(const weak_ptr<Y>& r);
```

24     *Effects:* Constructs a `shared_ptr` object that shares ownership with `r` and stores a copy of the pointer stored in `r`. If an exception is thrown, the constructor has no effect.

25     *Postconditions:* `use_count() == r.use_count()`.

26     *Throws:* `bad_weak_ptr` when `r.expired()`.

27     *Remarks:* This constructor shall not participate in overload resolution unless `Y*` is compatible with `T*`.

```
template<class Y, class D> shared_ptr(unique_ptr<Y, D>&& r);
```

28     *Remarks:* This constructor shall not participate in overload resolution unless `Y*` is compatible with `T*` and `unique_ptr<Y, D>::pointer` is convertible to `element_type*`.

29     *Effects:* If `r.get() == nullptr`, equivalent to `shared_ptr()`. Otherwise, if `D` is not a reference type, equivalent to `shared_ptr(r.release(), r.get_deleter())`. Otherwise, equivalent to `shared_ptr(r.release(), ref(r.get_deleter()))`. If an exception is thrown, the constructor has no effect.

### 23.11.3.2 shared\_ptr destructor

[util.smartptr.shared.dest]

```
~shared_ptr();
```

1     *Effects:*

- (1.1) — If `*this` is empty or shares ownership with another `shared_ptr` instance (`use_count() > 1`), there are no side effects.
- (1.2) — Otherwise, if `*this` owns an object `p` and a deleter `d`, `d(p)` is called.
- (1.3) — Otherwise, `*this` owns a pointer `p`, and `delete p` is called.

2 [ *Note:* Since the destruction of `*this` decreases the number of instances that share ownership with `*this` by one, after `*this` has been destroyed all `shared_ptr` instances that shared ownership with `*this` will report a `use_count()` that is one less than its previous value. — *end note* ]

### 23.11.3.3 shared\_ptr assignment

[util.smartptr.shared.assign]

```
shared_ptr& operator=(const shared_ptr& r) noexcept;
template<class Y> shared_ptr& operator=(const shared_ptr<Y>& r) noexcept;
```

1     *Effects:* Equivalent to `shared_ptr(r).swap(*this)`.

2     *Returns:* `*this`.

3 [ *Note:* The use count updates caused by the temporary object construction and destruction are not observable side effects, so the implementation may meet the effects (and the implied guarantees) via different means, without creating a temporary. In particular, in the example:

```
shared_ptr<int> p(new int);
shared_ptr<void> q(p);
p = p;
q = p;
```

both assignments may be no-ops. — *end note* ]

```
shared_ptr& operator=(shared_ptr&& r) noexcept;
```

```
template<class Y> shared_ptr& operator=(shared_ptr<Y>&& r) noexcept;
4   Effects: Equivalent to shared_ptr(std::move(r)).swap(*this).
5   Returns: *this.

template<class Y, class D> shared_ptr& operator=(unique_ptr<Y, D>&& r);
6   Effects: Equivalent to shared_ptr(std::move(r)).swap(*this).
7   Returns: *this.
```

**23.11.3.4 shared\_ptr modifiers**

[util.smartptr.shared.mod]

```
void swap(shared_ptr& r) noexcept;
1   Effects: Exchanges the contents of *this and r.

void reset() noexcept;
2   Effects: Equivalent to shared_ptr().swap(*this).

template<class Y> void reset(Y* p);
3   Effects: Equivalent to shared_ptr(p).swap(*this).

template<class Y, class D> void reset(Y* p, D d);
4   Effects: Equivalent to shared_ptr(p, d).swap(*this).

template<class Y, class D, class A> void reset(Y* p, D d, A a);
5   Effects: Equivalent to shared_ptr(p, d, a).swap(*this).
```

**23.11.3.5 shared\_ptr observers**

[util.smartptr.shared.obs]

```
element_type* get() const noexcept;
1   Returns: The stored pointer.

T& operator*() const noexcept;
2   Requires: get() != 0.
3   Returns: *get().

4   Remarks: When T is an array type or cv void, it is unspecified whether this member function is declared. If it is declared, it is unspecified what its return type is, except that the declaration (although not necessarily the definition) of the function shall be well-formed.

T* operator->() const noexcept;
5   Requires: get() != 0.
6   Returns: get().

7   Remarks: When T is an array type, it is unspecified whether this member function is declared. If it is declared, it is unspecified what its return type is, except that the declaration (although not necessarily the definition) of the function shall be well-formed.

element_type& operator[](ptrdiff_t i) const;
8   Requires: get() != 0 && i >= 0. If T is U[N], i < N.
9   Returns: get()[i].
```

10     *Remarks:* When T is not an array type, it is unspecified whether this member function is declared. If it is declared, it is unspecified what its return type is, except that the declaration (although not necessarily the definition) of the function shall be well-formed.

11     *Throws:* Nothing.

```
long use_count() const noexcept;
```

12     *Returns:* The number of `shared_ptr` objects, `*this` included, that share ownership with `*this`, or 0 when `*this` is empty.

13     *Synchronization:* None.

14     [*Note:* `get() == nullptr` does not imply a specific return value of `use_count()`. —end note]

15     [*Note:* `weak_ptr<T>::lock()` can affect the return value of `use_count()`. —end note]

16     [*Note:* When multiple threads can affect the return value of `use_count()`, the result should be treated as approximate. In particular, `use_count() == 1` does not imply that accesses through a previously destroyed `shared_ptr` have in any sense completed. —end note]

```
explicit operator bool() const noexcept;
```

17     *Returns:* `get() != 0`.

```
template<class U> bool owner_before(const shared_ptr<U>& b) const noexcept;
template<class U> bool owner_before(const weak_ptr<U>& b) const noexcept;
```

18     *Returns:* An unspecified value such that

(18.1)     — `x.owner_before(y)` defines a strict weak ordering as defined in ??;

(18.2)     — under the equivalence relation defined by `owner_before`, `!a.owner_before(b) && !b.owner_before(a)`, two `shared_ptr` or `weak_ptr` instances are equivalent if and only if they share ownership or are both empty.

### 23.11.3.6 `shared_ptr` creation

[util.smartptr.shared.create]

1     The common requirements that apply to all `make_shared` and `allocate_shared` overloads, unless specified otherwise, are described below.

```
template<class T, ...>
shared_ptr<T> make_shared(args);
template<class T, class A, ...>
shared_ptr<T> allocate_shared(const A& a, args);
```

2     *Requires:* A shall be an allocator (??).

3     *Effects:* Allocates memory for an object of type T (or U[N] when T is U[], where N is determined from args as specified by the concrete overload). The object is initialized from args as specified by the concrete overload. The `allocate_shared` templates use a copy of a (rebound for an unspecified `value_type`) to allocate memory. If an exception is thrown, the functions have no effect.

4     *Returns:* A `shared_ptr` instance that stores and owns the address of the newly constructed object.

5     *Postconditions:* `r.get() != 0 && r.use_count() == 1`, where r is the return value.

6     *Throws:* `bad_alloc`, or an exception thrown from `allocate` or from the initialization of the object.

7     *Remarks:*

- (7.1) — Implementations should perform no more than one memory allocation. [ *Note:* This provides efficiency equivalent to an intrusive smart pointer. — *end note* ]
- (7.2) — When an object of an array type U is specified to have an initial value of u (of the same type), this shall be interpreted to mean that each array element of the object has as its initial value the corresponding element from u.
- (7.3) — When an object of an array type is specified to have a default initial value, this shall be interpreted to mean that each array element of the object has a default initial value.
- (7.4) — When a (sub)object of a non-array type U is specified to have an initial value of v, or U(1...), where 1... is a list of constructor arguments, `make_shared` shall initialize this (sub)object via the expression `::new(pv) U(v)` or `::new(pv) U(1...)` respectively, where pv has type `void*` and points to storage suitable to hold an object of type U.
- (7.5) — When a (sub)object of a non-array type U is specified to have an initial value of v, or U(1...), where 1... is a list of constructor arguments, `allocate_shared` shall initialize this (sub)object via the expression
  - (7.5.1) — `allocator_traits<A2>::construct(a2, pv, v)` or
  - (7.5.2) — `allocator_traits<A2>::construct(a2, pv, 1...)`
 respectively, where pv points to storage suitable to hold an object of type U and a2 of type A2 is a rebound copy of the allocator a passed to `allocate_shared` such that its `value_type` is U.
- (7.6) — When a (sub)object of non-array type U is specified to have a default initial value, `make_shared` shall initialize this (sub)object via the expression `::new(pv) U()`, where pv has type `void*` and points to storage suitable to hold an object of type U.
- (7.7) — When a (sub)object of non-array type U is specified to have a default initial value, `allocate_shared` shall initialize this (sub)object via the expression `allocator_traits<A2>::construct(a2, pv)`, where pv points to storage suitable to hold an object of type U and a2 of type A2 is a rebound copy of the allocator a passed to `allocate_shared` such that its `value_type` is U.
- (7.8) — Array elements are initialized in ascending order of their addresses.
- (7.9) — When the lifetime of the object managed by the return value ends, or when the initialization of an array element throws an exception, the initialized elements should be destroyed in the reverse order of their construction.

[ *Note:* These functions will typically allocate more memory than `sizeof(T)` to allow for internal bookkeeping structures such as reference counts. — *end note* ]

```
template<class T, class... Args>
shared_ptr<T> make_shared(Args&&... args); // T is not array
template<class T, class A, class... Args>
shared_ptr<T> allocate_shared(const A& a, Args&&... args); // T is not array
```

8     *Returns:* A `shared_ptr` to an object of type T with an initial value `T(forward<Args>(args)....)`.

9     *Remarks:* These overloads shall only participate in overload resolution when T is not an array type. The `shared_ptr` constructors called by these functions enable `shared_from_this` with the address of the newly constructed object of type T.

10    [ *Example:*

```
shared_ptr<int> p = make_shared<int>(); // shared_ptr to int()
```

```

shared_ptr<vector<int>> q = make_shared<vector<int>>(16, 1);
// shared_ptr to vector of 16 elements with value 1

— end example]

template<class T> shared_ptr<T>
make_shared(size_t N); // T is U[]

template<class T, class A>
shared_ptr<T> allocate_shared(const A& a, size_t N); // T is U[]

11   Returns: A shared_ptr to an object of type U[N] with a default initial value, where U is remove_extent_t<T>.

12   Remarks: These overloads shall only participate in overload resolution when T is of the form U[].

13   [ Example:

      shared_ptr<double[]> p = make_shared<double[]>(1024);
      // shared_ptr to a value-initialized double[1024]
      shared_ptr<double[] [2] [2]> q = make_shared<double[] [2] [2]>(6);
      // shared_ptr to a value-initialized double[6] [2] [2]

      — end example]

      template<class T>
      shared_ptr<T> make_shared(); // T is U[N]

      template<class T, class A>
      shared_ptr<T> allocate_shared(const A& a); // T is U[N]

14   Returns: A shared_ptr to an object of type T with a default initial value.

15   Remarks: These overloads shall only participate in overload resolution when T is of the form U[N].

16   [ Example:

      shared_ptr<double[1024]> p = make_shared<double[1024]>();
      // shared_ptr to a value-initialized double[1024]
      shared_ptr<double[6] [2] [2]> q = make_shared<double[6] [2] [2]>();
      // shared_ptr to a value-initialized double[6] [2] [2]

      — end example]

      template<class T>
      shared_ptr<T> make_shared(size_t N,
                                const remove_extent_t<T>& u); // T is U[]

      template<class T, class A>
      shared_ptr<T> allocate_shared(const A& a, size_t N,
                                    const remove_extent_t<T>& u); // T is U[]

17   Returns: A shared_ptr to an object of type U[N], where U is remove_extent_t<T> and each array element has an initial value of u.

18   Remarks: These overloads shall only participate in overload resolution when T is of the form U[].

19   [ Example:

      shared_ptr<double[]> p = make_shared<double[]>(1024, 1.0);
      // shared_ptr to a double[1024], where each element is 1.0
      shared_ptr<double[] [2]> q = make_shared<double[] [2]>(6, {1.0, 0.0});
```

```

    // shared_ptr to a double[6][2], where each double[2] element is {1.0, 0.0}
    shared_ptr<vector<int>[]> r = make_shared<vector<int>[]>(4, {1, 2});
    // shared_ptr to a vector<int>[4], where each vector has contents {1, 2}
    — end example]

template<class T>
shared_ptr<T> make_shared(const remove_extent_t<T>& u);           // T is U[N]
template<class T, class A>
shared_ptr<T> allocate_shared(const A& a,
                           const remove_extent_t<T>& u); // T is U[N]

20   Returns: A shared_ptr to an object of type T, where each array element of type remove_extent_t<T>
      has an initial value of u.

21   Remarks: These overloads shall only participate in overload resolution when T is of the form U[N]. 

22   [ Example:
    shared_ptr<double[1024]> p = make_shared<double[1024]>(1.0);
    // shared_ptr to a double[1024], where each element is 1.0
    shared_ptr<double[6][2]> q = make_shared<double[6][2]>({1.0, 0.0});
    // shared_ptr to a double[6][2], where each double[2] element is {1.0, 0.0}
    shared_ptr<vector<int>[4]> r = make_shared<vector<int>[4]>({1, 2});
    // shared_ptr to a vector<int>[4], where each vector has contents {1, 2}
    — end example]

```

### 23.11.3.7 shared\_ptr comparison

[util.smartptr.shared.cmp]

```

template<class T, class U>
bool operator==(const shared_ptr<T>& a, const shared_ptr<U>& b) noexcept;

1     Returns: a.get() == b.get(). 

template<class T, class U>
bool operator<(const shared_ptr<T>& a, const shared_ptr<U>& b) noexcept;

2     Returns: less<>()(a.get(), b.get()).

3     [ Note: Defining a comparison function allows shared_ptr objects to be used as keys in associative
      containers. — end note ]

template<class T>
bool operator==(const shared_ptr<T>& a, nullptr_t) noexcept;
template<class T>
bool operator==(nullptr_t, const shared_ptr<T>& a) noexcept;

4     Returns: !a.

template<class T>
bool operator!=(const shared_ptr<T>& a, nullptr_t) noexcept;
template<class T>
bool operator!=(nullptr_t, const shared_ptr<T>& a) noexcept;

5     Returns: (bool)a.

template<class T>
bool operator<(const shared_ptr<T>& a, nullptr_t) noexcept;

```

```
template<class T>
bool operator<(nullptr_t, const shared_ptr<T>& a) noexcept;
```

6     *Returns:* The first function template returns

```
    less<typename shared_ptr<T>::element_type*>()(a.get(), nullptr)
```

The second function template returns

```
    less<typename shared_ptr<T>::element_type*>()(nullptr, a.get())
```

```
template<class T>
bool operator>(const shared_ptr<T>& a, nullptr_t) noexcept;
template<class T>
bool operator>(nullptr_t, const shared_ptr<T>& a) noexcept;
```

7     *Returns:* The first function template returns `nullptr < a`. The second function template returns `a < nullptr`.

```
template<class T>
bool operator<=(const shared_ptr<T>& a, nullptr_t) noexcept;
template<class T>
bool operator<=(nullptr_t, const shared_ptr<T>& a) noexcept;
```

8     *Returns:* The first function template returns `!(nullptr < a)`. The second function template returns `!(a < nullptr)`.

```
template<class T>
bool operator>=(const shared_ptr<T>& a, nullptr_t) noexcept;
template<class T>
bool operator>=(nullptr_t, const shared_ptr<T>& a) noexcept;
```

9     *Returns:* The first function template returns `!(a < nullptr)`. The second function template returns `!(nullptr < a)`.

### 23.11.3.8 shared\_ptr specialized algorithms

[util.smartptr.shared.spec]

```
template<class T>
void swap(shared_ptr<T>& a, shared_ptr<T>& b) noexcept;
```

1     *Effects:* Equivalent to `a.swap(b)`.

### 23.11.3.9 shared\_ptr casts

[util.smartptr.shared.cast]

```
template<class T, class U>
shared_ptr<T> static_pointer_cast(const shared_ptr<U>& r) noexcept;
```

1     *Requires:* The expression `static_cast<T*>((U*)nullptr)` shall be well-formed.

2     *Returns:*

```
    shared_ptr<T>(r, static_cast<typename shared_ptr<T>::element_type*>(r.get()))
```

3     [*Note:* The seemingly equivalent expression `shared_ptr<T>(static_cast<T*>(r.get()))` will eventually result in undefined behavior, attempting to delete the same object twice. —*end note*]

```
template<class T, class U>
```

```
shared_ptr<T> dynamic_pointer_cast(const shared_ptr<U>& r) noexcept;
```

4     *Requires:* The expression `dynamic_cast<T*>((U*)nullptr)` shall be well-formed. The expression `dynamic_cast<typename shared_ptr<T>::element_type*>(r.get())` shall be well formed and shall have well-defined behavior.

5     *Returns:*

(5.1)     — When `dynamic_cast<typename shared_ptr<T>::element_type*>(r.get())` returns a non-null value `p`, `shared_ptr<T>(r, p)`.

(5.2)     — Otherwise, `shared_ptr<T>()`.

6     [*Note:* The seemingly equivalent expression `shared_ptr<T>(dynamic_cast<T*>(r.get()))` will eventually result in undefined behavior, attempting to delete the same object twice. — *end note*]

```
template<class T, class U>
shared_ptr<T> const_pointer_cast(const shared_ptr<U>& r) noexcept;
```

7     *Requires:* The expression `const_cast<T*>((U*)nullptr)` shall be well-formed.

8     *Returns:*

```
shared_ptr<T>(r, const_cast<typename shared_ptr<T>::element_type*>(r.get()))
```

9     [*Note:* The seemingly equivalent expression `shared_ptr<T>(const_cast<T*>(r.get()))` will eventually result in undefined behavior, attempting to delete the same object twice. — *end note*]

```
template<class T, class U>
shared_ptr<T> reinterpret_pointer_cast(const shared_ptr<U>& r) noexcept;
```

10    *Requires:* The expression `reinterpret_cast<T*>((U*)nullptr)` shall be well-formed.

11    *Returns:*

```
shared_ptr<T>(r, reinterpret_cast<typename shared_ptr<T>::element_type*>(r.get()))
```

12    [*Note:* The seemingly equivalent expression `shared_ptr<T>(reinterpret_cast<T*>(r.get()))` will eventually result in undefined behavior, attempting to delete the same object twice. — *end note*]

### 23.11.3.10 get\_deleter

[util.smartptr.getdeleter]

```
template<class D, class T>
D* get_deleter(const shared_ptr<T>& p) noexcept;
```

1     *Returns:* If `p` owns a deleter `d` of type cv-unqualified `D`, returns `addressof(d)`; otherwise returns `nullptr`. The returned pointer remains valid as long as there exists a `shared_ptr` instance that owns `d`. [*Note:* It is unspecified whether the pointer remains valid longer than that. This can happen if the implementation doesn't destroy the deleter until all `weak_ptr` instances that share ownership with `p` have been destroyed. — *end note*]

### 23.11.3.11 shared\_ptr I/O

[util.smartptr.shared.io]

```
template<class E, class T, class Y>
basic_ostream<E, T>& operator<<(basic_ostream<E, T>& os, const shared_ptr<Y>& p);
```

1     *Effects:* As if by: `os << p.get();`

2     *Returns:* `os`.

### 23.11.4 Class template `weak_ptr`

[`util.smartptr.weak`]

- <sup>1</sup> The `weak_ptr` class template stores a weak reference to an object that is already managed by a `shared_ptr`. To access the object, a `weak_ptr` can be converted to a `shared_ptr` using the member function `lock`.

```
namespace std {
    template<class T> class weak_ptr {
        public:
            using element_type = remove_extent_t<T>;
            // ??, constructors
            constexpr weak_ptr() noexcept;
            template<class Y>
                weak_ptr(const shared_ptr<Y>& r) noexcept;
            weak_ptr(const weak_ptr& r) noexcept;
            template<class Y>
                weak_ptr(const weak_ptr<Y>& r) noexcept;
            weak_ptr(weak_ptr&& r) noexcept;
            template<class Y>
                weak_ptr(weak_ptr<Y>&& r) noexcept;
            // ??, destructor
            ~weak_ptr();
            // ??, assignment
            weak_ptr& operator=(const weak_ptr& r) noexcept;
            template<class Y>
                weak_ptr& operator=(const weak_ptr<Y>& r) noexcept;
            template<class Y>
                weak_ptr& operator=(const shared_ptr<Y>& r) noexcept;
            weak_ptr& operator=(weak_ptr&& r) noexcept;
            template<class Y>
                weak_ptr& operator=(weak_ptr<Y>&& r) noexcept;
            // ??, modifiers
            void swap(weak_ptr& r) noexcept;
            void reset() noexcept;
            // ??, observers
            long use_count() const noexcept;
            bool expired() const noexcept;
            shared_ptr<T> lock() const noexcept;
            template<class U>
                bool owner_before(const shared_ptr<U>& b) const noexcept;
            template<class U>
                bool owner_before(const weak_ptr<U>& b) const noexcept;
        };
        template<class T>
            weak_ptr(shared_ptr<T>) -> weak_ptr<T>;
    };
}
```

```
// ??, specialized algorithms
template<class T>
void swap(weak_ptr<T>& a, weak_ptr<T>& b) noexcept;
}
```

- <sup>2</sup> Specializations of `weak_ptr` shall be `CopyConstructible` and `CopyAssignable`, allowing their use in standard containers. The template parameter `T` of `weak_ptr` may be an incomplete type.

#### 23.11.4.1 `weak_ptr` constructors

[`util.smartptr.weak.const`]

```
constexpr weak_ptr() noexcept;
```

- <sup>1</sup> *Effects:* Constructs an empty `weak_ptr` object.

- <sup>2</sup> *Postconditions:* `use_count() == 0`.

```
weak_ptr(const weak_ptr& r) noexcept;
template<class Y> weak_ptr(const weak_ptr<Y>& r) noexcept;
template<class Y> weak_ptr(const shared_ptr<Y>& r) noexcept;
```

- <sup>3</sup> *Remarks:* The second and third constructors shall not participate in overload resolution unless `Y*` is compatible with `T*`.

- <sup>4</sup> *Effects:* If `r` is empty, constructs an empty `weak_ptr` object; otherwise, constructs a `weak_ptr` object that shares ownership with `r` and stores a copy of the pointer stored in `r`.

- <sup>5</sup> *Postconditions:* `use_count() == r.use_count()`.

```
weak_ptr(weak_ptr&& r) noexcept;
template<class Y> weak_ptr(weak_ptr<Y>&& r) noexcept;
```

- <sup>6</sup> *Remarks:* The second constructor shall not participate in overload resolution unless `Y*` is compatible with `T*`.

- <sup>7</sup> *Effects:* Move constructs a `weak_ptr` instance from `r`.

- <sup>8</sup> *Postconditions:* `*this` shall contain the old value of `r`. `r` shall be empty. `r.use_count() == 0`.

#### 23.11.4.2 `weak_ptr` destructor

[`util.smartptr.weak.dest`]

```
~weak_ptr();
```

- <sup>1</sup> *Effects:* Destroys this `weak_ptr` object but has no effect on the object its stored pointer points to.

#### 23.11.4.3 `weak_ptr` assignment

[`util.smartptr.weak.assign`]

```
weak_ptr& operator=(const weak_ptr& r) noexcept;
template<class Y> weak_ptr& operator=(const weak_ptr<Y>& r) noexcept;
template<class Y> weak_ptr& operator=(const shared_ptr<Y>& r) noexcept;
```

- <sup>1</sup> *Effects:* Equivalent to `weak_ptr(r).swap(*this)`.

- <sup>2</sup> *Remarks:* The implementation may meet the effects (and the implied guarantees) via different means, without creating a temporary object.

- <sup>3</sup> *Returns:* `*this`.

```
weak_ptr& operator=(weak_ptr&& r) noexcept;
template<class Y> weak_ptr& operator=(weak_ptr<Y>&& r) noexcept;
```

- <sup>4</sup> *Effects:* Equivalent to `weak_ptr(std::move(r)).swap(*this)`.

5       *Returns:* `*this`.

#### 23.11.4.4 `weak_ptr` modifiers

[`util.smartptr.weak.mod`]

```
void swap(weak_ptr& r) noexcept;
```

1       *Effects:* Exchanges the contents of `*this` and `r`.

```
void reset() noexcept;
```

2       *Effects:* Equivalent to `weak_ptr().swap(*this)`.

#### 23.11.4.5 `weak_ptr` observers

[`util.smartptr.weak.obs`]

```
long use_count() const noexcept;
```

1       *Returns:* 0 if `*this` is empty; otherwise, the number of `shared_ptr` instances that share ownership with `*this`.

```
bool expired() const noexcept;
```

2       *Returns:* `use_count() == 0`.

```
shared_ptr<T> lock() const noexcept;
```

3       *Returns:* `expired() ? shared_ptr<T>() : shared_ptr<T>(*this)`, executed atomically.

```
template<class U> bool owner_before(const shared_ptr<U>& b) const noexcept;
```

```
template<class U> bool owner_before(const weak_ptr<U>& b) const noexcept;
```

4       *Returns:* An unspecified value such that

(4.1)     — `x.owner_before(y)` defines a strict weak ordering as defined in ??;

(4.2)     — under the equivalence relation defined by `owner_before`, `!a.owner_before(b) && !b.owner_before(a)`, two `shared_ptr` or `weak_ptr` instances are equivalent if and only if they share ownership or are both empty.

#### 23.11.4.6 `weak_ptr` specialized algorithms

[`util.smartptr.weak.spec`]

```
template<class T>
```

```
void swap(weak_ptr<T>& a, weak_ptr<T>& b) noexcept;
```

1       *Effects:* Equivalent to `a.swap(b)`.

#### 23.11.5 Class template `owner_less`

[`util.smartptr.ownerless`]

1       The class template `owner_less` allows ownership-based mixed comparisons of shared and weak pointers.

```
namespace std {
    template<class T = void> struct owner_less;

    template<class T> struct owner_less<shared_ptr<T>> {
        bool operator()(const shared_ptr<T>&, const shared_ptr<T>&) const noexcept;
        bool operator()(const shared_ptr<T>&, const weak_ptr<T>&) const noexcept;
        bool operator()(const weak_ptr<T>&, const shared_ptr<T>&) const noexcept;
    };

    template<class T> struct owner_less<weak_ptr<T>> {
        bool operator()(const weak_ptr<T>&, const weak_ptr<T>&) const noexcept;
    };
}
```

```

    bool operator()(const shared_ptr<T>&, const weak_ptr<T>&) const noexcept;
    bool operator()(const weak_ptr<T>&, const shared_ptr<T>&) const noexcept;
};

template<> struct owner_less<void> {
    template<class T, class U>
    bool operator()(const shared_ptr<T>&, const shared_ptr<U>&) const noexcept;
    template<class T, class U>
    bool operator()(const shared_ptr<T>&, const weak_ptr<U>&) const noexcept;
    template<class T, class U>
    bool operator()(const weak_ptr<T>&, const shared_ptr<U>&) const noexcept;
    template<class T, class U>
    bool operator()(const weak_ptr<T>&, const weak_ptr<U>&) const noexcept;

    using is_transparent = unspecified;
};
}

```

<sup>2</sup> `operator()(x, y)` shall return `x.owner_before(y)`. [Note: Note that

- (2.1) — `operator()` defines a strict weak ordering as defined in ??;
- (2.2) — under the equivalence relation defined by `operator()`, `!operator()(a, b) && !operator()(b, a)`, two `shared_ptr` or `weak_ptr` instances are equivalent if and only if they share ownership or are both empty.

— end note]

### 23.11.6 Class template `enable_shared_from_this`

[`util.smartptr.enab`]

<sup>1</sup> A class `T` can inherit from `enable_shared_from_this<T>` to inherit the `shared_from_this` member functions that obtain a `shared_ptr` instance pointing to `*this`.

<sup>2</sup> [Example:

```

struct X: public enable_shared_from_this<X> { };

int main() {
    shared_ptr<X> p(new X);
    shared_ptr<X> q = p->shared_from_this();
    assert(p == q);
    assert(!p.owner_before(q) && !q.owner_before(p)); // p and q share ownership
}

```

— end example]

```

namespace std {
    template<class T> class enable_shared_from_this {
protected:
    constexpr enable_shared_from_this() noexcept;
    enable_shared_from_this(const enable_shared_from_this&) noexcept;
    enable_shared_from_this& operator=(const enable_shared_from_this&) noexcept;
    ~enable_shared_from_this();
}

```

```

public:
    shared_ptr<T> shared_from_this();
    shared_ptr<T const> shared_from_this() const;
    weak_ptr<T> weak_from_this() noexcept;
    weak_ptr<T const> weak_from_this() const noexcept;

private:
    mutable weak_ptr<T> weak_this; // exposition only
};

}

```

- 3 The template parameter T of `enable_shared_from_this` may be an incomplete type.

```

constexpr enable_shared_from_this() noexcept;
enable_shared_from_this(const enable_shared_from_this<T>&) noexcept;

```

- 4 *Effects:* Value-initializes `weak_this`.

```
enable_shared_from_this<T>& operator=(const enable_shared_from_this<T>&) noexcept;
```

- 5 *Returns:* `*this`.

- 6 [ *Note:* `weak_this` is not changed. — end note ]

```

shared_ptr<T>      shared_from_this();
shared_ptr<T const> shared_from_this() const;

```

- 7 *Returns:* `shared_ptr<T>(weak_this)`.

```

weak_ptr<T>      weak_from_this() noexcept;
weak_ptr<T const> weak_from_this() const noexcept;

```

- 8 *Returns:* `weak_this`.

### 23.11.7 Smart pointer hash support

[[util.smartptr.hash](#)]

```
template<class T, class D> struct hash<unique_ptr<T, D>>;
```

- 1 Letting UP be `unique_ptr<T,D>`, the specialization `hash<UP>` is enabled (??) if and only if `hash<typename UP::pointer>` is enabled. When enabled, for an object p of type UP, `hash<UP>()(p)` shall evaluate to the same value as `hash<typename UP::pointer>()(p.get())`. The member functions are not guaranteed to be `noexcept`.

```
template<class T> struct hash<shared_ptr<T>>;
```

- 2 For an object p of type `shared_ptr<T>`, `hash<shared_ptr<T>>()(p)` shall evaluate to the same value as `hash<typename shared_ptr<T>::element_type*>()(p.get())`.

### 23.11.8 Atomic specializations for smart pointers

[[util.smartptr.atomic](#)]

- 1 The library provides partial specializations of the `atomic` template for shared-ownership smart pointers. The behavior of all operations is as specified in ??, unless specified otherwise. The template parameter T of these partial specializations may be an incomplete type.
- 2 All changes to an atomic smart pointer in this subclause, and all associated `use_count` increments, are guaranteed to be performed atomically. Associated `use_count` decrements are sequenced after the atomic operation, but are not required to be part of it. Any associated deletion and deallocation are sequenced after the atomic update step and are not part of the atomic operation. [ *Note:* If the atomic operation uses locks,

locks acquired by the implementation will be held when any `use_count` adjustments are performed, and will not be held when any destruction or deallocation resulting from this is performed. — *end note*]

### 23.11.8.1 Atomic specialization for `shared_ptr`

[`util.smartptr.atomic.shared`]

```
namespace std {
    template<class T> struct atomic<shared_ptr<T>> {
        using value_type = shared_ptr<T>;
        static constexpr bool is_always_lock_free = implementation-defined;

        bool is_lock_free() const noexcept;
        void store(shared_ptr<T> desired, memory_order order = memory_order::seq_cst) noexcept;
        shared_ptr<T> load(memory_order order = memory_order::seq_cst) const noexcept;
        operator shared_ptr<T>() const noexcept;

        shared_ptr<T> exchange(shared_ptr<T> desired,
                               memory_order order = memory_order::seq_cst) noexcept;

        bool compare_exchange_weak(shared_ptr<T>& expected, shared_ptr<T> desired,
                                  memory_order success, memory_order failure) noexcept;
        bool compare_exchange_strong(shared_ptr<T>& expected, shared_ptr<T> desired,
                                    memory_order success, memory_order failure) noexcept;

        bool compare_exchange_weak(shared_ptr<T>& expected, shared_ptr<T> desired,
                                  memory_order order = memory_order::seq_cst) noexcept;
        bool compare_exchange_strong(shared_ptr<T>& expected, shared_ptr<T> desired,
                                    memory_order order = memory_order::seq_cst) noexcept;

        constexpr atomic() noexcept = default;
        atomic(shared_ptr<T> desired) noexcept;
        atomic(const atomic&) = delete;
        void operator=(const atomic&) = delete;
        void operator=(shared_ptr<T> desired) noexcept;

        private:
            shared_ptr<T> p; // exposition only
    };
}

constexpr atomic() noexcept = default;
```

<sup>1</sup> *Effects:* Initializes `p{}`.

`atomic(shared_ptr<T> desired)` noexcept;

<sup>2</sup> *Effects:* Initializes the object with the value `desired`. Initialization is not an atomic operation (??). [Note: It is possible to have an access to an atomic object `A` race with its construction, for example, by communicating the address of the just-constructed object `A` to another thread via `memory_order::relaxed` operations on a suitable atomic pointer variable, and then immediately accessing `A` in the receiving thread. This results in undefined behavior. — *end note*]

```

void store(shared_ptr<T> desired, memory_order order = memory_order::seq_cst) noexcept;
3   Requires: The order argument shall not be memory_order::consume, memory_order::acquire, nor
               memory_order::acq_rel.
4   Effects: Atomically replaces the value pointed to by this with the value of desired as if by
              p.swap(desired). Memory is affected according to the value of order.

void operator=(shared_ptr<T> desired) noexcept;
5   Effects: Equivalent to store(desired).

shared_ptr<T> load(memory_order order = memory_order::seq_cst) const noexcept;
6   Requires: order shall not be memory_order::release nor memory_order::acq_rel.
7   Effects: Memory is affected according to the value of order.
8   Returns: Atomically returns p.

operator shared_ptr<T>() const noexcept;
9   Effects: Equivalent to: return load();

shared_ptr<T> exchange(shared_ptr<T> desired, memory_order order = memory_order::seq_cst) noexcept;
10  Effects: Atomically replaces p with desired as if by p.swap(desired). Memory is affected according
              to the value of order. This is an atomic read-modify-write operation (?).
11  Returns: Atomically returns the value of p immediately before the effects.

bool compare_exchange_weak(shared_ptr<T>& expected, shared_ptr<T> desired,
                         memory_order success, memory_order failure) noexcept;
bool compare_exchange_strong(shared_ptr<T>& expected, shared_ptr<T> desired,
                           memory_order success, memory_order failure) noexcept;

12  Requires: failure shall not be memory_order::release nor memory_order::acq_rel.
13  Effects: If p is equivalent to expected, assigns desired to p and has synchronization semantics
              corresponding to the value of success, otherwise assigns p to expected and has synchronization
              semantics corresponding to the value of failure.
14  Returns: true if p was equivalent to expected, false otherwise.

15  Remarks: Two shared_ptr objects are equivalent if they store the same pointer value and either share
              ownership, or both are empty. The weak form may fail spuriously. See ?.

16  If the operation returns true, expected is not accessed after the atomic update and the operation is an
      atomic read-modify-write operation (?) on the memory pointed to by this. Otherwise, the operation
      is an atomic load operation on that memory, and expected is updated with the existing value read
      from the atomic object in the attempted atomic update. The use_count update corresponding to the
      write to expected is part of the atomic operation. The write to expected itself is not required to be
      part of the atomic operation.

bool compare_exchange_weak(shared_ptr<T>& expected, shared_ptr<T> desired,
                         memory_order order = memory_order::seq_cst) noexcept;
17  Effects: Equivalent to:
              return compare_exchange_weak(expected, desired, order, fail_order);

```

where `fail_order` is the same as `order` except that a value of `memory_order::acq_rel` shall be replaced by the value `memory_order::acquire` and a value of `memory_order::release` shall be replaced by the value `memory_order::relaxed`.

```
bool compare_exchange_strong(shared_ptr<T>& expected, shared_ptr<T> desired,
                             memory_order order = memory_order::seq_cst) noexcept;
```

18     *Effects:* Equivalent to:

```
    return compare_exchange_strong(expected, desired, order, fail_order);
```

where `fail_order` is the same as `order` except that a value of `memory_order::acq_rel` shall be replaced by the value `memory_order::acquire` and a value of `memory_order::release` shall be replaced by the value `memory_order::relaxed`.

### 23.11.8.2 Atomic specialization for `weak_ptr`

[`util.smartptr.atomic.weak`]

```
namespace std {
    template<class T> struct atomic<weak_ptr<T>> {
        using value_type = weak_ptr<T>;
        static constexpr bool is_always_lock_free = implementation-defined;

        bool is_lock_free() const noexcept;
        void store(weak_ptr<T> desired, memory_order order = memory_order::seq_cst) noexcept;
        weak_ptr<T> load(memory_order order = memory_order::seq_cst) const noexcept;
        operator weak_ptr<T>() const noexcept;

        weak_ptr<T> exchange(weak_ptr<T> desired,
                            memory_order order = memory_order::seq_cst) noexcept;

        bool compare_exchange_weak(weak_ptr<T>& expected, weak_ptr<T> desired,
                                  memory_order success, memory_order failure) noexcept;
        bool compare_exchange_strong(weak_ptr<T>& expected, weak_ptr<T> desired,
                                    memory_order success, memory_order failure) noexcept;

        bool compare_exchange_weak(weak_ptr<T>& expected, weak_ptr<T> desired,
                                  memory_order order = memory_order::seq_cst) noexcept;
        bool compare_exchange_strong(weak_ptr<T>& expected, weak_ptr<T> desired,
                                    memory_order order = memory_order::seq_cst) noexcept;

        constexpr atomic() noexcept = default;
        atomic(weak_ptr<T> desired) noexcept;
        atomic(const atomic&) = delete;
        void operator=(const atomic&) = delete;
        void operator=(weak_ptr<T> desired) noexcept;

        private:
            weak_ptr<T> p; // exposition only
    };
}

constexpr atomic() noexcept = default;
```

1     *Effects:* Initializes `p{}`.

```

atomic(weak_ptr<T> desired) noexcept;

2   Effects: Initializes the object with the value desired. Initialization is not an atomic operation (??). [ Note: It is possible to have an access to an atomic object A race with its construction, for example, by communicating the address of the just-constructed object A to another thread via memory_order::relaxed operations on a suitable atomic pointer variable, and then immediately accessing A in the receiving thread. This results in undefined behavior. — end note ]

void store(weak_ptr<T> desired, memory_order order = memory_order::seq_cst) noexcept;

3   Requires: The order argument shall not be memory_order::consume, memory_order::acquire, nor memory_order::acq_rel.

4   Effects: Atomically replaces the value pointed to by this with the value of desired as if by p.swap(desired). Memory is affected according to the value of order.

void operator=(weak_ptr<T> desired) noexcept;

5   Effects: Equivalent to store(desired).

weak_ptr<T> load(memory_order order = memory_order::seq_cst) const noexcept;

6   Requires: order shall not be memory_order::release nor memory_order::acq_rel.

7   Effects: Memory is affected according to the value of order.

8   Returns: Atomically returns p.

operator weak_ptr<T>() const noexcept;

9   Effects: Equivalent to: return load();

weak_ptr<T> exchange(weak_ptr<T> desired, memory_order order = memory_order::seq_cst) noexcept;

10  Effects: Atomically replaces p with desired as if by p.swap(desired). Memory is affected according to the value of order. This is an atomic read-modify-write operation (??).

11  Returns: Atomically returns the value of p immediately before the effects.

bool compare_exchange_weak(weak_ptr<T>& expected, weak_ptr<T> desired,
                           memory_order success, memory_order failure) noexcept;
bool compare_exchange_strong(weak_ptr<T>& expected, weak_ptr<T> desired,
                            memory_order success, memory_order failure) noexcept;

12  Requires: failure shall not be memory_order::release nor memory_order::acq_rel.

13  Effects: If p is equivalent to expected, assigns desired to p and has synchronization semantics corresponding to the value of success, otherwise assigns p to expected and has synchronization semantics corresponding to the value of failure.

14  Returns: true if p was equivalent to expected, false otherwise.

15  Remarks: Two weak_ptr objects are equivalent if they store the same pointer value and either share ownership, or both are empty. The weak form may fail spuriously. See ??.

16  If the operation returns true, expected is not accessed after the atomic update and the operation is an atomic read-modify-write operation (??) on the memory pointed to by this. Otherwise, the operation is an atomic load operation on that memory, and expected is updated with the existing value read from the atomic object in the attempted atomic update. The use_count update corresponding to the

```

write to `expected` is part of the atomic operation. The write to `expected` itself is not required to be part of the atomic operation.

```
bool compare_exchange_weak(weak_ptr<T>& expected, weak_ptr<T> desired,
                           memory_order order = memory_order::seq_cst) noexcept;
```

17     *Effects:* Equivalent to:

```
    return compare_exchange_weak(expected, desired, order, fail_order);
```

where `fail_order` is the same as `order` except that a value of `memory_order::acq_rel` shall be replaced by the value `memory_order::acquire` and a value of `memory_order::release` shall be replaced by the value `memory_order::relaxed`.

```
bool compare_exchange_strong(weak_ptr<T>& expected, weak_ptr<T> desired,
                             memory_order order = memory_order::seq_cst) noexcept;
```

18     *Effects:* Equivalent to:

```
    return compare_exchange_strong(expected, desired, order, fail_order);
```

where `fail_order` is the same as `order` except that a value of `memory_order::acq_rel` shall be replaced by the value `memory_order::acquire` and a value of `memory_order::release` shall be replaced by the value `memory_order::relaxed`.

## 23.12 Memory resources

[mem.res]

### 23.12.1 Header <memory\_resource> synopsis

[mem.res.syn]

```
namespace std::pmr {
    // ??, class memory_resource
    class memory_resource;

    bool operator==(const memory_resource& a, const memory_resource& b) noexcept;
    bool operator!=(const memory_resource& a, const memory_resource& b) noexcept;

    // ??, class template polymorphic_allocator
    template<class Tp> class polymorphic_allocator;

    template<class T1, class T2>
    bool operator==(const polymorphic_allocator<T1>& a,
                     const polymorphic_allocator<T2>& b) noexcept;
    template<class T1, class T2>
    bool operator!=(const polymorphic_allocator<T1>& a,
                     const polymorphic_allocator<T2>& b) noexcept;

    // ??, global memory resources
    memory_resource* new_delete_resource() noexcept;
    memory_resource* null_memory_resource() noexcept;
    memory_resource* set_default_resource(memory_resource* r) noexcept;
    memory_resource* get_default_resource() noexcept;

    // ??, pool resource classes
    struct pool_options;
    class synchronized_pool_resource;
```

```

    class unsynchronized_pool_resource;
    class monotonic_buffer_resource;
}

```

### 23.12.2 Class `memory_resource`

[mem.res.class]

- <sup>1</sup> The `memory_resource` class is an abstract interface to an unbounded set of classes encapsulating memory resources.

```

namespace std::pmr {
    class memory_resource {
        static constexpr size_t max_align = alignof(max_align_t); // exposition only

        public:
            virtual ~memory_resource();

            [[nodiscard]] void* allocate(size_t bytes, size_t alignment = max_align);
            void deallocate(void* p, size_t bytes, size_t alignment = max_align);

            bool is_equal(const memory_resource& other) const noexcept;

        private:
            virtual void* do_allocate(size_t bytes, size_t alignment) = 0;
            virtual void do_deallocate(void* p, size_t bytes, size_t alignment) = 0;

            virtual bool do_is_equal(const memory_resource& other) const noexcept = 0;
    };
}

```

#### 23.12.2.1 `memory_resource` public member functions

[mem.res.public]

`~memory_resource();`

- <sup>1</sup> *Effects:* Destroys this `memory_resource`.

`[[nodiscard]] void* allocate(size_t bytes, size_t alignment = max_align);`

- <sup>2</sup> *Effects:* Equivalent to: `return do_allocate(bytes, alignment);`

`void deallocate(void* p, size_t bytes, size_t alignment = max_align);`

- <sup>3</sup> *Effects:* Equivalent to `do_deallocate(p, bytes, alignment)`.

`bool is_equal(const memory_resource& other) const noexcept;`

- <sup>4</sup> *Effects:* Equivalent to: `return do_is_equal(other);`

#### 23.12.2.2 `memory_resource` private virtual member functions

[mem.res.private]

`virtual void* do_allocate(size_t bytes, size_t alignment) = 0;`

- <sup>1</sup> *Requires:* `alignment` shall be a power of two.

- <sup>2</sup> *Returns:* A derived class shall implement this function to return a pointer to allocated storage (??) with a size of at least `bytes`. The returned storage is aligned to the specified alignment, if such alignment is supported (??); otherwise it is aligned to `max_align`.

3        *Throws:* A derived class implementation shall throw an appropriate exception if it is unable to allocate memory with the requested size and alignment.

```
virtual void do_deallocate(void* p, size_t bytes, size_t alignment) = 0;
```

4        *Requires:* p shall have been returned from a prior call to `allocate(bytes, alignment)` on a memory resource equal to `*this`, and the storage at p shall not yet have been deallocated.

5        *Effects:* A derived class shall implement this function to dispose of allocated storage.

6        *Throws:* Nothing.

```
virtual bool do_is_equal(const memory_resource& other) const noexcept = 0;
```

7        *Returns:* A derived class shall implement this function to return `true` if memory allocated from `this` can be deallocated from `other` and vice-versa, otherwise `false`. [ *Note:* The most-derived type of `other` might not match the type of `this`. For a derived class D, an implementation of this function could immediately return `false` if `dynamic_cast<const D*>(&other) == nullptr`. — *end note* ]

### 23.12.2.3 `memory_resource` equality

[mem.res.eq]

```
bool operator==(const memory_resource& a, const memory_resource& b) noexcept;
```

1        *Returns:* `&a == &b || a.is_equal(b)`.

```
bool operator!=(const memory_resource& a, const memory_resource& b) noexcept;
```

2        *Returns:* `!(a == b)`.

### 23.12.3 Class template `polymorphic_allocator`

[mem.polyallocator.class]

1 A specialization of class template `pmr::polymorphic_allocator` conforms to the `Allocator` requirements (??). Constructed with different memory resources, different instances of the same specialization of `pmr::polymorphic_allocator` can exhibit entirely different allocation behavior. This runtime polymorphism allows objects that use `polymorphic_allocator` to behave as if they used different allocator types at run time even though they use the same static allocator type.

```
namespace std::pmr {
    template<class Tp>
    class polymorphic_allocator {
        memory_resource* memory_rsrc; // exposition only

    public:
        using value_type = Tp;

        // ??, constructors
        polymorphic_allocator() noexcept;
        polymorphic_allocator(memory_resource* r);

        polymorphic_allocator(const polymorphic_allocator& other) = default;

        template<class U>
        polymorphic_allocator(const polymorphic_allocator<U>& other) noexcept;

        polymorphic_allocator& operator=(const polymorphic_allocator& rhs) = delete;
```

```

// ??, member functions

[[nodiscard]] Tp* allocate(size_t n);
void deallocate(Tp* p, size_t n);

template<class T, class... Args>
void construct(T* p, Args&&... args);

template<class T1, class T2, class... Args1, class... Args2>
void construct(pair<T1, T2>* p, piecewise_construct_t,
               tuple<Args1...> x, tuple<Args2...> y);
template<class T1, class T2>
void construct(pair<T1, T2>* p);
template<class T1, class T2, class U, class V>
void construct(pair<T1, T2>* p, U&& x, V&& y);
template<class T1, class T2, class U, class V>
void construct(pair<T1, T2>* p, const pair<U, V>& pr);
template<class T1, class T2, class U, class V>
void construct(pair<T1, T2>* p, pair<U, V>&& pr);

template<class T>
void destroy(T* p);

polymorphic_allocator select_on_container_copy_construction() const;

memory_resource* resource() const;
};

}

```

**23.12.3.1 polymorphic\_allocator constructors**

[mem.polyallocator.ctor]

`polymorphic_allocator() noexcept;`1      *Effects:* Sets `memory_rsrc` to `get_default_resource()`.`polymorphic_allocator(memory_resource* r);`2      *Requires:* `r` is non-null.3      *Effects:* Sets `memory_rsrc` to `r`.4      *Throws:* Nothing.5      [ *Note:* This constructor provides an implicit conversion from `memory_resource*`. —end note]

```

template<class U>
polymorphic_allocator(const polymorphic_allocator<U>& other) noexcept;

```

6      *Effects:* Sets `memory_rsrc` to `other.resource()`.**23.12.3.2 polymorphic\_allocator member functions**

[mem.polyallocator.mem]

`[[nodiscard]] Tp* allocate(size_t n);`1      *Effects:* Equivalent to:

```

return static_cast<Tp*>(memory_rsrc->allocate(n * sizeof(Tp), alignof(Tp)));

```

```

void deallocate(Tp* p, size_t n);

2   Requires: p was allocated from a memory resource x, equal to *memory_rsrc, using x.allocate(n *
      sizeof(Tp), alignof(Tp)).

3   Effects: Equivalent to memory_rsrc->deallocate(p, n * sizeof(Tp), alignof(Tp)).

4   Throws: Nothing.

template<class T, class... Args>
void construct(T* p, Args&&... args);

5   Requires: Uses-allocator construction of T with allocator resource() (see ??) and constructor arguments
      std::forward<Args>(args)... is well-formed. [Note: Uses-allocator construction is always well-
      formed for types that do not use allocators. —end note]

6   Effects: Construct a T object in the storage whose address is represented by p by uses-allocator
      construction with allocator resource() and constructor arguments std::forward<Args>(args).....

7   Throws: Nothing unless the constructor for T throws.

template<class T1, class T2, class... Args1, class... Args2>
void construct(pair<T1, T2>* p, piecewise_construct_t, tuple<Args1...> x, tuple<Args2...> y);

8   [Note: This member function and the construct member functions that follow are overloads for
      piecewise construction of pairs (??). —end note]

9   Effects: Let xprime be a tuple constructed from x according to the appropriate rule from the following
      list. [Note: The following description can be summarized as constructing a pair<T1, T2> object in the
      storage whose address is represented by p, as if by separate uses-allocator construction with allocator
      resource() (??) of p->first using the elements of x and p->second using the elements of y. —end
      note]

(9.1) — If uses_allocator_v<T1,memory_resource*> is false
      and is_constructible_v<T1,Args1...> is true,
      then xprime is x.

(9.2) — Otherwise, if uses_allocator_v<T1,memory_resource*> is true
      and is_constructible_v<T1,allocator_arg_t,memory_resource*,Args1...> is true,
      then xprime is tuple_cat(make_tuple(allocator_arg, resource()), std::move(x)).

(9.3) — Otherwise, if uses_allocator_v<T1,memory_resource*> is true
      and is_constructible_v<T1,Args1...,memory_resource*> is true,
      then xprime is tuple_cat(std::move(x), make_tuple(resource())).

(9.4) — Otherwise the program is ill formed.

Let yprime be a tuple constructed from y according to the appropriate rule from the following list:

(9.5) — If uses_allocator_v<T2,memory_resource*> is false
      and is_constructible_v<T2,Args2...> is true,
      then yprime is y.

(9.6) — Otherwise, if uses_allocator_v<T2,memory_resource*> is true
      and is_constructible_v<T2,allocator_arg_t,memory_resource*,Args2...> is true,
      then yprime is tuple_cat(make_tuple(allocator_arg, resource()), std::move(y)).

```

- (9.7) — Otherwise, if `uses_allocator_v<T2,memory_resource*>` is true  
and `is_constructible_v<T2,Args2...,memory_resource*>` is true,  
then `yprime` is `tuple_cat(std::move(y), make_tuple(resource()))`.
- (9.8) — Otherwise the program is ill formed.

Then, using `piecewise_construct`, `xprime`, and `yprime` as the constructor arguments, this function constructs a `pair<T1, T2>` object in the storage whose address is represented by `p`.

```
template<class T1, class T2>
void construct(pair<T1, T2>* p);
```

10     *Effects:* Equivalent to:

```
construct(p, piecewise_construct, tuple<>(), tuple<>());
```

```
template<class T1, class T2, class U, class V>
void construct(pair<T1, T2>* p, U&& x, V&& y);
```

11     *Effects:* Equivalent to:

```
construct(p, piecewise_construct,
          forward_as_tuple(std::forward<U>(x)),
          forward_as_tuple(std::forward<V>(y)));
```

```
template<class T1, class T2, class U, class V>
void construct(pair<T1, T2>* p, const pair<U, V>& pr);
```

12     *Effects:* Equivalent to:

```
construct(p, piecewise_construct,
          forward_as_tuple(pr.first),
          forward_as_tuple(pr.second));
```

```
template<class T1, class T2, class U, class V>
void construct(pair<T1, T2>* p, pair<U, V>&& pr);
```

13     *Effects:* Equivalent to:

```
construct(p, piecewise_construct,
          forward_as_tuple(std::forward<U>(pr.first)),
          forward_as_tuple(std::forward<V>(pr.second)));
```

```
template<class T>
void destroy(T* p);
```

14     *Effects:* As if by `p->~T()`.

```
polymorphic_allocator select_on_container_copy_construction() const;
```

15     *Returns:* `polymorphic_allocator()`.

16     *[Note:* The memory resource is not propagated. — *end note*]

```
memory_resource* resource() const;
```

17     *Returns:* `memory_rsrc`.

### 23.12.3.3 polymorphic\_allocator equality

[mem.polyallocator.eq]

```
template<class T1, class T2>
bool operator==(const polymorphic_allocator<T1>& a,
```

```

    const polymorphic_allocator<T2>& b) noexcept;
1   Returns: *a.resource() == *b.resource().

template<class T1, class T2>
bool operator!=(const polymorphic_allocator<T1>& a,
                  const polymorphic_allocator<T2>& b) noexcept;

2   Returns: !(a == b).

```

### 23.12.4 Access to program-wide `memory_resource` objects

[mem.res.global]

```
memory_resource* new_delete_resource() noexcept;
```

1     >Returns: A pointer to a static-duration object of a type derived from `memory_resource` that can serve as a resource for allocating memory using `::operator new` and `::operator delete`. The same value is returned every time this function is called. For a return value `p` and a memory resource `r`, `p->is_equal(r)` returns `&r == p`.

```
memory_resource* null_memory_resource() noexcept;
```

2     >Returns: A pointer to a static-duration object of a type derived from `memory_resource` for which `allocate()` always throws `bad_alloc` and for which `deallocate()` has no effect. The same value is returned every time this function is called. For a return value `p` and a memory resource `r`, `p->is_equal(r)` returns `&r == p`.

3     The *default memory resource pointer* is a pointer to a memory resource that is used by certain facilities when an explicit memory resource is not supplied through the interface. Its initial value is the return value of `new_delete_resource()`.

```
memory_resource* set_default_resource(memory_resource* r) noexcept;
```

4     `Effects:` If `r` is non-null, sets the value of the default memory resource pointer to `r`, otherwise sets the default memory resource pointer to `new_delete_resource()`.

5     >Returns: The previous value of the default memory resource pointer.

6     `Remarks:` Calling the `set_default_resource` and `get_default_resource` functions shall not incur a data race. A call to the `set_default_resource` function shall synchronize with subsequent calls to the `set_default_resource` and `get_default_resource` functions.

```
memory_resource* get_default_resource() noexcept;
```

7     >Returns: The current value of the default memory resource pointer.

### 23.12.5 Pool resource classes

[mem.res.pool]

#### 23.12.5.1 Classes `synchronized_pool_resource` and `unsynchronized_pool_resource` [mem.res.pool.overview]

1     The `synchronized_pool_resource` and `unsynchronized_pool_resource` classes (collectively called *pool resource classes*) are general-purpose memory resources having the following qualities:

- (1.1) — Each resource frees its allocated memory on destruction, even if `deallocate` has not been called for some of the allocated blocks.
- (1.2) — A pool resource consists of a collection of *pools*, serving requests for different block sizes. Each individual pool manages a collection of *chunks* that are in turn divided into blocks of uniform size, returned via

calls to `do_allocate`. Each call to `do_allocate(size, alignment)` is dispatched to the pool serving the smallest blocks accommodating at least `size` bytes.

- (1.3) — When a particular pool is exhausted, allocating a block from that pool results in the allocation of an additional chunk of memory from the *upstream allocator* (supplied at construction), thus replenishing the pool. With each successive replenishment, the chunk size obtained increases geometrically. [ *Note:* By allocating memory in chunks, the pooling strategy increases the chance that consecutive allocations will be close together in memory. — *end note* ]
  - (1.4) — Allocation requests that exceed the largest block size of any pool are fulfilled directly from the upstream allocator.
  - (1.5) — A `pool_options` struct may be passed to the pool resource constructors to tune the largest block size and the maximum chunk size.
- <sup>2</sup> A `synchronized_pool_resource` may be accessed from multiple threads without external synchronization and may have thread-specific pools to reduce synchronization costs. An `unsynchronized_pool_resource` class may not be accessed from multiple threads simultaneously and thus avoids the cost of synchronization entirely in single-threaded applications.

```
namespace std::pmr {
    struct pool_options {
        size_t max_blocks_per_chunk = 0;
        size_t largest_required_pool_block = 0;
    };

    class synchronized_pool_resource : public memory_resource {
    public:
        synchronized_pool_resource(const pool_options& opts, memory_resource* upstream);

        synchronized_pool_resource()
            : synchronized_pool_resource(pool_options(), get_default_resource()) {}
        explicit synchronized_pool_resource(memory_resource* upstream)
            : synchronized_pool_resource(pool_options(), upstream) {}
        explicit synchronized_pool_resource(const pool_options& opts)
            : synchronized_pool_resource(opts, get_default_resource()) {}

        synchronized_pool_resource(const synchronized_pool_resource&) = delete;
        virtual ~synchronized_pool_resource();

        synchronized_pool_resource& operator=(const synchronized_pool_resource&) = delete;

        void release();
        memory_resource* upstream_resource() const;
        pool_options options() const;

    protected:
        void* do_allocate(size_t bytes, size_t alignment) override;
        void do_deallocate(void* p, size_t bytes, size_t alignment) override;

        bool do_is_equal(const memory_resource& other) const noexcept override;
    };
}
```

```

class unsynchronized_pool_resource : public memory_resource {
public:
    unsynchronized_pool_resource(const pool_options& opts, memory_resource* upstream);

    unsynchronized_pool_resource()
        : unsynchronized_pool_resource(pool_options(), get_default_resource()) {}
    explicit unsynchronized_pool_resource(memory_resource* upstream)
        : unsynchronized_pool_resource(pool_options(), upstream) {}
    explicit unsynchronized_pool_resource(const pool_options& opts)
        : unsynchronized_pool_resource(opts, get_default_resource()) {}

    unsynchronized_pool_resource(const unsynchronized_pool_resource&) = delete;
    virtual ~unsynchronized_pool_resource();

    unsynchronized_pool_resource& operator=(const unsynchronized_pool_resource&) = delete;

    void release();
    memory_resource* upstream_resource() const;
    pool_options options() const;

protected:
    void* do_allocate(size_t bytes, size_t alignment) override;
    void do_deallocate(void* p, size_t bytes, size_t alignment) override;

    bool do_is_equal(const memory_resource& other) const noexcept override;
};

}

```

**23.12.5.2 pool\_options data members**

[mem.res.pool.options]

- <sup>1</sup> The members of `pool_options` comprise a set of constructor options for pool resources. The effect of each option on the pool resource behavior is described below:

`size_t max_blocks_per_chunk;`

- <sup>2</sup> The maximum number of blocks that will be allocated at once from the upstream memory resource (???) to replenish a pool. If the value of `max_blocks_per_chunk` is zero or is greater than an implementation-defined limit, that limit is used instead. The implementation may choose to use a smaller value than is specified in this field and may use different values for different pools.

`size_t largest_required_pool_block;`

- <sup>3</sup> The largest allocation size that is required to be fulfilled using the pooling mechanism. Attempts to allocate a single block larger than this threshold will be allocated directly from the upstream memory resource. If `largest_required_pool_block` is zero or is greater than an implementation-defined limit, that limit is used instead. The implementation may choose a pass-through threshold larger than specified in this field.

**23.12.5.3 Pool resource constructors and destructors**

[mem.res.pool.ctor]

`synchronized_pool_resource(const pool_options& opts, memory_resource* upstream);`

```
unsynchronized_pool_resource(const pool_options& opts, memory_resource* upstream);
```

- 1     *Requires:* `upstream` is the address of a valid memory resource.
- 2     *Effects:* Constructs a pool resource object that will obtain memory from `upstream` whenever the pool resource is unable to satisfy a memory request from its own internal data structures. The resulting object will hold a copy of `upstream`, but will not own the resource to which `upstream` points. [ *Note:* The intention is that calls to `upstream->allocate()` will be substantially fewer than calls to `this->allocate()` in most cases. — *end note* ] The behavior of the pooling mechanism is tuned according to the value of the `opts` argument.
- 3     *Throws:* Nothing unless `upstream->allocate()` throws. It is unspecified if, or under what conditions, this constructor calls `upstream->allocate()`.

```
virtual ~synchronized_pool_resource();
virtual ~unsynchronized_pool_resource();
```

- 4     *Effects:* Calls `release()`.

#### 23.12.5.4 Pool resource members

[mem.res.pool.mem]

```
void release();
```

- 1     *Effects:* Calls `upstream_resource()->deallocate()` as necessary to release all allocated memory. [ *Note:* The memory is released back to `upstream_resource()` even if `deallocate` has not been called for some of the allocated blocks. — *end note* ]

```
memory_resource* upstream_resource() const;
```

- 2     *Returns:* The value of the `upstream` argument provided to the constructor of this object.

```
pool_options options() const;
```

- 3     *Returns:* The options that control the pooling behavior of this resource. The values in the returned struct may differ from those supplied to the pool resource constructor in that values of zero will be replaced with implementation-defined defaults, and sizes may be rounded to unspecified granularity.

```
void* do_allocate(size_t bytes, size_t alignment) override;
```

- 4     *Returns:* A pointer to allocated storage (??) with a size of at least `bytes`. The size and alignment of the allocated memory shall meet the requirements for a class derived from `memory_resource` (??).

- 5     *Effects:* If the pool selected for a block of size `bytes` is unable to satisfy the memory request from its own internal data structures, it will call `upstream_resource()->allocate()` to obtain more memory. If `bytes` is larger than that which the largest pool can handle, then memory will be allocated using `upstream_resource()->allocate()`.

- 6     *Throws:* Nothing unless `upstream_resource()->allocate()` throws.

```
void do_deallocate(void* p, size_t bytes, size_t alignment) override;
```

- 7     *Effects:* Returns the memory at `p` to the pool. It is unspecified if, or under what circumstances, this operation will result in a call to `upstream_resource()->deallocate()`.

- 8     *Throws:* Nothing.

```
bool synchronized_pool_resource::do_is_equal(
```

```

    const memory_resource& other) const noexcept override;
9     Returns: this == dynamic_cast<const synchronized_pool_resource*>(&other).

bool unsynchronized_pool_resource::do_is_equal(
    const memory_resource& other) const noexcept override;
10    Returns: this == dynamic_cast<const unsynchronized_pool_resource*>(&other).

```

### 23.12.6 Class `monotonic_buffer_resource` [mem.res.monotonic.buffer]

<sup>1</sup> A `monotonic_buffer_resource` is a special-purpose memory resource intended for very fast memory allocations in situations where memory is used to build up a few objects and then is released all at once when the memory resource object is destroyed. It has the following qualities:

- (1.1) — A call to `deallocate` has no effect, thus the amount of memory consumed increases monotonically until the resource is destroyed.
- (1.2) — The program can supply an initial buffer, which the allocator uses to satisfy memory requests.
- (1.3) — When the initial buffer (if any) is exhausted, it obtains additional buffers from an *upstream* memory resource supplied at construction. Each additional buffer is larger than the previous one, following a geometric progression.
- (1.4) — It is intended for access from one thread of control at a time. Specifically, calls to `allocate` and `deallocate` do not synchronize with one another.
- (1.5) — It frees the allocated memory on destruction, even if `deallocate` has not been called for some of the allocated blocks.

```

namespace std::pmr {
    class monotonic_buffer_resource : public memory_resource {
        memory_resource* upstream_rsrc;      // exposition only
        void* current_buffer;                // exposition only
        size_t next_buffer_size;             // exposition only

    public:
        explicit monotonic_buffer_resource(memory_resource* upstream);
        monotonic_buffer_resource(size_t initial_size, memory_resource* upstream);
        monotonic_buffer_resource(void* buffer, size_t buffer_size, memory_resource* upstream);

        monotonic_buffer_resource()
            : monotonic_buffer_resource(get_default_resource()) {}
        explicit monotonic_buffer_resource(size_t initial_size)
            : monotonic_buffer_resource(initial_size, get_default_resource()) {}
        monotonic_buffer_resource(void* buffer, size_t buffer_size)
            : monotonic_buffer_resource(buffer, buffer_size, get_default_resource()) {}

        monotonic_buffer_resource(const monotonic_buffer_resource&) = delete;

        virtual ~monotonic_buffer_resource();

        monotonic_buffer_resource& operator=(const monotonic_buffer_resource&) = delete;

        void release();
    };
}
```

```

    memory_resource* upstream_resource() const;

protected:
    void* do_allocate(size_t bytes, size_t alignment) override;
    void do_deallocate(void* p, size_t bytes, size_t alignment) override;

    bool do_is_equal(const memory_resource& other) const noexcept override;
};

}

```

### 23.12.6.1 monotonic\_buffer\_resource constructor and destructor

[mem.res.monotonic.buffer.ctor]

```

explicit monotonic_buffer_resource(memory_resource* upstream);
monotonic_buffer_resource(size_t initial_size, memory_resource* upstream);

```

- 1 *Requires:* `upstream` shall be the address of a valid memory resource. `initial_size`, if specified, shall be greater than zero.
- 2 *Effects:* Sets `upstream_rsrc` to `upstream` and `current_buffer` to `nullptr`. If `initial_size` is specified, sets `next_buffer_size` to at least `initial_size`; otherwise sets `next_buffer_size` to an implementation-defined size.

```
monotonic_buffer_resource(void* buffer, size_t buffer_size, memory_resource* upstream);
```

- 3 *Requires:* `upstream` shall be the address of a valid memory resource. `buffer_size` shall be no larger than the number of bytes in `buffer`.
- 4 *Effects:* Sets `upstream_rsrc` to `upstream`, `current_buffer` to `buffer`, and `next_buffer_size` to `buffer_size` (but not less than 1), then increases `next_buffer_size` by an implementation-defined growth factor (which need not be integral).

```
~monotonic_buffer_resource();
```

- 5 *Effects:* Calls `release()`.

### 23.12.6.2 monotonic\_buffer\_resource members

[mem.res.monotonic.buffer.mem]

```
void release();
```

- 1 *Effects:* Calls `upstream_rsrc->deallocate()` as necessary to release all allocated memory.
- 2 [ *Note:* The memory is released back to `upstream_rsrc` even if some blocks that were allocated from `this` have not been deallocated from `this`. — end note ]

```
memory_resource* upstream_resource() const;
```

- 3 *Returns:* The value of `upstream_rsrc`.

```
void* do_allocate(size_t bytes, size_t alignment) override;
```

- 4 *Returns:* A pointer to allocated storage (??) with a size of at least `bytes`. The size and alignment of the allocated memory shall meet the requirements for a class derived from `memory_resource` (??).
- 5 *Effects:* If the unused space in `current_buffer` can fit a block with the specified `bytes` and `alignment`, then allocate the return block from `current_buffer`; otherwise set `current_buffer` to `upstream_rsrc->allocate(n, m)`, where `n` is not less than `max(bytes, next_buffer_size)` and `m` is not less

than `alignment`, and increase `next_buffer_size` by an implementation-defined growth factor (which need not be integral), then allocate the return block from the newly-allocated `current_buffer`.

6     *Throws:* Nothing unless `upstream_rsrc->allocate()` throws.

```
void do_deallocate(void* p, size_t bytes, size_t alignment) override;
```

7     *Effects:* None.

8     *Throws:* Nothing.

9     *Remarks:* Memory used by this resource increases monotonically until its destruction.

```
bool do_is_equal(const memory_resource& other) const noexcept override;
```

10    *Returns:* `this == dynamic_cast<const monotonic_buffer_resource*>(&other)`.

### 23.13 Class template `scoped_allocator_adaptor`

[allocator.adaptor]

#### 23.13.1 Header <`scoped_allocator`> synopsis

[allocator.adaptor.syn]

```
namespace std {
    // class template scoped allocator adaptor
    template<class OuterAlloc, class... InnerAllocs>
        class scoped_allocator_adaptor;

    // ??, scoped allocator operators
    template<class OuterA1, class OuterA2, class... InnerAllocs>
        bool operator==(const scoped_allocator_adaptor<OuterA1, InnerAllocs...>& a,
                          const scoped_allocator_adaptor<OuterA2, InnerAllocs...>& b) noexcept;
    template<class OuterA1, class OuterA2, class... InnerAllocs>
        bool operator!=(const scoped_allocator_adaptor<OuterA1, InnerAllocs...>& a,
                          const scoped_allocator_adaptor<OuterA2, InnerAllocs...>& b) noexcept;
}
```

<sup>1</sup> The class template `scoped_allocator_adaptor` is an allocator template that specifies the memory resource (the outer allocator) to be used by a container (as any other allocator does) and also specifies an inner allocator resource to be passed to the constructor of every element within the container. This adaptor is instantiated with one outer and zero or more inner allocator types. If instantiated with only one allocator type, the inner allocator becomes the `scoped_allocator_adaptor` itself, thus using the same allocator resource for the container and every element within the container and, if the elements themselves are containers, each of their elements recursively. If instantiated with more than one allocator, the first allocator is the outer allocator for use by the container, the second allocator is passed to the constructors of the container's elements, and, if the elements themselves are containers, the third allocator is passed to the elements' elements, and so on. If containers are nested to a depth greater than the number of allocators, the last allocator is used repeatedly, as in the single-allocator case, for any remaining recursions. [ *Note:* The `scoped_allocator_adaptor` is derived from the outer allocator type so it can be substituted for the outer allocator type in most expressions. — *end note* ]

```
namespace std {
    template<class OuterAlloc, class... InnerAllocs>
        class scoped_allocator_adaptor : public OuterAlloc {
    private:
        using OuterTraits = allocator_traits<OuterAlloc>; // exposition only
        scoped_allocator_adaptor<InnerAllocs...> inner; // exposition only
```

```

public:
    using outer_allocator_type = OuterAlloc;
    using inner_allocator_type = see below;

    using value_type           = typename OuterTraits::value_type;
    using size_type             = typename OuterTraits::size_type;
    using difference_type       = typename OuterTraits::difference_type;
    using pointer               = typename OuterTraits::pointer;
    using const_pointer         = typename OuterTraits::const_pointer;
    using void_pointer          = typename OuterTraits::void_pointer;
    using const_void_pointer    = typename OuterTraits::const_void_pointer;

    using propagate_on_container_copy_assignment = see below;
    using propagate_on_container_move_assignment = see below;
    using propagate_on_container_swap           = see below;
    using is_always_equal                   = see below;

template<class Tp>

    void construct(pair<T1, T2>* p, pair<U, V>&& x);

    template<class T>
    void destroy(T* p);

    scoped_allocator_adaptor select_on_container_copy_construction() const;
};

template<class OuterAlloc, class... InnerAllocs>
scoped_allocator_adaptor(OuterAlloc, InnerAllocs...)
    -> scoped_allocator_adaptor<OuterAlloc, InnerAllocs...>;
}

```

### 23.13.2 Scoped allocator adaptor member types

[allocator.adaptor.types]

```

using inner_allocator_type = see below;

1   Type: scoped_allocator_adaptor<OuterAlloc> if sizeof...(InnerAllocs) is zero; otherwise,
    scoped_allocator_adaptor<InnerAllocs...>.

using propagate_on_container_copy_assignment = see below;

2   Type: true_type if allocator_traits<A>::propagate_on_container_copy_assignment::value is
    true for any A in the set of OuterAlloc and InnerAllocs...; otherwise, false_type.

using propagate_on_container_move_assignment = see below;

3   Type: true_type if allocator_traits<A>::propagate_on_container_move_assignment::value is
    true for any A in the set of OuterAlloc and InnerAllocs...; otherwise, false_type.

using propagate_on_container_swap = see below;

4   Type: true_type if allocator_traits<A>::propagate_on_container_swap::value is true for any
    A in the set of OuterAlloc and InnerAllocs...; otherwise, false_type.

using is_always_equal = see below;

5   Type: true_type if allocator_traits<A>::is_always_equal::value is true for every A in the set
    of OuterAlloc and InnerAllocs...; otherwise, false_type.

```

### 23.13.3 Scoped allocator adaptor constructors

[allocator.adaptor.cnstr]

```
scoped_allocator_adaptor();
```

- 1     *Effects:* Value-initializes the OuterAlloc base class and the inner allocator object.

```
template<class OuterA2>
scoped_allocator_adaptor(OuterA2&& outerAlloc, const InnerAllocs... innerAllocs) noexcept;
```

- 2     *Effects:* Initializes the OuterAlloc base class with std::forward<OuterA2>(outerAlloc) and inner with innerAllocs... (hence recursively initializing each allocator within the adaptor with the corresponding allocator from the argument list).

- 3     *Remarks:* This constructor shall not participate in overload resolution unless is\_constructible\_v<OuterAlloc, OuterA2> is true.

```
scoped_allocator_adaptor(const scoped_allocator_adaptor& other) noexcept;
```

- 4     *Effects:* initializes each allocator within the adaptor with the corresponding allocator from other.

```
scoped_allocator_adaptor(scoped_allocator_adaptor&& other) noexcept;
```

- 5     *Effects:* Move constructs each allocator within the adaptor with the corresponding allocator from other.

```
template<class OuterA2>
scoped_allocator_adaptor(
    const scoped_allocator_adaptor<OuterA2, InnerAllocs...>& other) noexcept;
```

- 6     *Effects:* initializes each allocator within the adaptor with the corresponding allocator from other.

- 7     *Remarks:* This constructor shall not participate in overload resolution unless is\_constructible\_v<OuterAlloc, const OuterA2> is true.

```
template<class OuterA2>
scoped_allocator_adaptor(scoped_allocator_adaptor<OuterA2, InnerAllocs...>&& other) noexcept;
```

- 8     *Effects:* initializes each allocator within the adaptor with the corresponding allocator rvalue from other.

- 9     *Remarks:* This constructor shall not participate in overload resolution unless is\_constructible\_v<OuterAlloc, OuterA2> is true.

### 23.13.4 Scoped allocator adaptor members

[allocator.adaptor.members]

- 1 In the construct member functions, OUTERMOST(x) is x if x does not have an outer\_allocator() member function and OUTERMOST(x.outer\_allocator()) otherwise; OUTERMOST\_ALLOC\_TRAITS(x) is allocator\_traits<decltype(OUTERMOST(x))>. [Note: OUTERMOST(x) and OUTERMOST\_ALLOC\_TRAITS(x) are recursive operations. It is incumbent upon the definition of outer\_allocator() to ensure that the recursion terminates. It will terminate for all instantiations of scoped\_allocator\_adaptor. — end note]

```
inner_allocator_type& inner_allocator() noexcept;
const inner_allocator_type& inner_allocator() const noexcept;
```

- 2     *Returns:* \*this if sizeof...(InnerAllocs) is zero; otherwise, inner.

```
outer_allocator_type& outer_allocator() noexcept;
```

- 3     *Returns:* static\_cast<OuterAlloc&>(\*this).

```

const outer_allocator_type& outer_allocator() const noexcept;
4     Returns: static_cast<const OuterAlloc&>(*this).

[[nodiscard]] pointer allocate(size_type n);
5     Returns: allocator_traits<OuterAlloc>::allocate(outer_allocator(), n).

[[nodiscard]] pointer allocate(size_type n, const void_pointer hint);
6     Returns: allocator_traits<OuterAlloc>::allocate(outer_allocator(), n, hint).

void deallocate(pointer p, size_type n) noexcept;
7     Effects: As if by: allocator_traits<OuterAlloc>::deallocate(outer_allocator(), p, n);

size_type max_size() const;
8     Returns: allocator_traits<OuterAlloc>::max_size(outer_allocator()).

template<class T, class... Args>
void construct(T* p, Args&&... args);

9     Effects:
(9.1) — If uses_allocator_v<T, inner_allocator_type> is false and is_constructible_v<T,
      Args...> is true, calls:
          OUTERMOST_ALLOC_TRAITS(*this)::construct(
              OUTERMOST(*this), p, std::forward<Args>(args)...)

(9.2) — Otherwise, if uses_allocator_v<T, inner_allocator_type> is true and is_constructible_v<T,
      allocator_arg_t, inner_allocator_type&, Args...> is true, calls:
          OUTERMOST_ALLOC_TRAITS(*this)::construct(
              OUTERMOST(*this), p, allocator_arg, inner_allocator(), std::forward<Args>(args)...)

(9.3) — Otherwise, if uses_allocator_v<T, inner_allocator_type> is true and is_constructible_v<T,
      Args..., inner_allocator_type&> is true, calls:
          OUTERMOST_ALLOC_TRAITS(*this)::construct(
              OUTERMOST(*this), p, std::forward<Args>(args)..., inner_allocator())

(9.4) — Otherwise, the program is ill-formed. [Note: An error will result if uses_allocator evaluates
      to true but the specific constructor does not take an allocator. This definition prevents a silent
      failure to pass an inner allocator to a contained element. —end note]

template<class T1, class T2, class... Args1, class... Args2>
void construct(pair<T1, T2>* p, piecewise_construct_t, tuple<Args1...> x, tuple<Args2...> y);
10    Requires: All of the types in Args1 and Args2 shall be CopyConstructible (Table ??).

11    Effects: Constructs a tuple object xprime from x by the following rules:
(11.1) — If uses_allocator_v<T1, inner_allocator_type> is false and is_constructible_v<T1,
      Args1...> is true, then xprime is x.

(11.2) — Otherwise, if uses_allocator_v<T1, inner_allocator_type> is true and is_constructible_v<T1,
      allocator_arg_t, inner_allocator_type&, Args1...> is true, then xprime is:
          tuple_cat(
              tuple<allocator_arg_t, inner_allocator_type>(allocator_arg, inner_allocator()),
              std::move(x))

```

(11.3) — Otherwise, if `uses_allocator_v<T1, inner_allocator_type>` is `true` and `is_constructible_v<T1, Args1..., inner_allocator_type&>` is `true`, then `xprime` is:

```
tuple_cat(std::move(x), tuple<inner_allocator_type&>(inner_allocator()))
```

(11.4) — Otherwise, the program is ill-formed.

and constructs a `tuple` object `yprime` from `y` by the following rules:

(11.5) — If `uses_allocator_v<T2, inner_allocator_type>` is `false` and `is_constructible_v<T2, Args2...>` is `true`, then `yprime` is `y`.

(11.6) — Otherwise, if `uses_allocator_v<T2, inner_allocator_type>` is `true` and `is_constructible_v<T2, allocator_arg_t, inner_allocator_type&, Args2...>` is `true`, then `yprime` is:

```
tuple_cat(
    tuple<allocator_arg_t, inner_allocator_type&>(allocator_arg, inner_allocator()),
    std::move(y))
```

(11.7) — Otherwise, if `uses_allocator_v<T2, inner_allocator_type>` is `true` and `is_constructible_v<T2, Args2..., inner_allocator_type&>` is `true`, then `yprime` is:

```
tuple_cat(std::move(y), tuple<inner_allocator_type&>(inner_allocator()))
```

(11.8) — Otherwise, the program is ill-formed.

then calls:

```
OUTERMOST_ALLOC_TRAITS(*this)::construct(
    OUTERMOST(*this), p, piecewise_construct, std::move(xprime), std::move(yprime))
```

```
template<class T1, class T2>
void construct(pair<T1, T2>* p);
```

12     *Effects:* Equivalent to:

```
construct(p, piecewise_construct, tuple<>(), tuple<>());
```

```
template<class T1, class T2, class U, class V>
void construct(pair<T1, T2>* p, U&& x, V&& y);
```

13     *Effects:* Equivalent to:

```
construct(p, piecewise_construct,
    forward_as_tuple(std::forward<U>(x)),
    forward_as_tuple(std::forward<V>(y)));
```

```
template<class T1, class T2, class U, class V>
void construct(pair<T1, T2>* p, const pair<U, V>& x);
```

14     *Effects:* Equivalent to:

```
construct(p, piecewise_construct,
    forward_as_tuple(x.first),
    forward_as_tuple(x.second));
```

```
template<class T1, class T2, class U, class V>
void construct(pair<T1, T2>* p, pair<U, V>&& x);
```

15     *Effects:* Equivalent to:

```
construct(p, piecewise_construct,
    forward_as_tuple(std::forward<U>(x.first)),
```

```

        forward_as_tuple(std::forward<V>(x.second)));
}

template<class T>
void destroy(T* p);

16   Effects: Calls OUTERMOST_ALLOC_TRAITS(*this)::destroy(OUTERMOST(*this), p).

scoped_allocator_adaptor select_on_container_copy_construction() const;

17   Returns: A new scoped_allocator_adaptor object where each allocator A in the adaptor is initialized
      from the result of calling allocator_traits<A>::select_on_container_copy_construction() on
      the corresponding allocator in *this.

```

### 23.13.5 Scoped allocator operators

[**scoped.adaptor.operators**]

```

template<class OuterA1, class OuterA2, class... InnerAllocs>
bool operator==(const scoped_allocator_adaptor<OuterA1, InnerAllocs...>& a,
                  const scoped_allocator_adaptor<OuterA2, InnerAllocs...>& b) noexcept;

1   Returns: If sizeof...(InnerAllocs) is zero,
           a.outer_allocator() == b.outer_allocator()
           otherwise
           a.outer_allocator() == b.outer_allocator() && a.inner_allocator() == b.inner_allocator()

template<class OuterA1, class OuterA2, class... InnerAllocs>
bool operator!=(const scoped_allocator_adaptor<OuterA1, InnerAllocs...>& a,
                  const scoped_allocator_adaptor<OuterA2, InnerAllocs...>& b) noexcept;

2   Returns: !(a == b).

```

### 23.14 Function objects

[**function.objects**]

- <sup>1</sup> A *function object type* is an object type (??) that can be the type of the *postfix-expression* in a function call (??, ??).<sup>227</sup> A *function object* is an object of a function object type. In the places where one would expect to pass a pointer to a function to an algorithmic template (??), the interface is specified to accept a function object. This not only makes algorithmic templates work with pointers to functions, but also enables them to work with arbitrary function objects.

#### 23.14.1 Header <functional> synopsis

[**functional.syn**]

```

namespace std {
    // ??, invoke
    template<class F, class... Args>
        invoke_result_t<F, Args...> invoke(F&& f, Args&&... args)
            noexcept(is_nothrow_invocable_v<F, Args...>);

    // ??, reference_wrapper
    template<class T> class reference_wrapper;

    template<class T> reference_wrapper<T> ref(T&) noexcept;
    template<class T> reference_wrapper<const T> cref(const T&) noexcept;
    template<class T> void ref(const T&&) = delete;
}

```

<sup>227</sup>) Such a type is a function pointer or a class type which has a member `operator()` or a class type which has a conversion to a pointer to function.

```

template<class T> void cref(const T&&) = delete;

template<class T> reference_wrapper<T> ref(reference_wrapper<T>) noexcept;
template<class T> reference_wrapper<const T> cref(reference_wrapper<T>) noexcept;

// ??, arithmetic operations
template<class T = void> struct plus;
template<class T = void> struct minus;
template<class T = void> struct multiplies;
template<class T = void> struct divides;
template<class T = void> struct modulus;
template<class T = void> struct negate;
template<> struct plus<void>;
template<> struct minus<void>;
template<> struct multiplies<void>;
template<> struct divides<void>;
template<> struct modulus<void>;
template<> struct negate<void>;

// ??, comparisons
template<class T = void> struct equal_to;
template<class T = void> struct not_equal_to;
template<class T = void> struct greater;
template<class T = void> struct less;
template<class T = void> struct greater_equal;
template<class T = void> struct less_equal;
template<> struct equal_to<void>;
template<> struct not_equal_to<void>;
template<> struct greater<void>;
template<> struct less<void>;
template<> struct greater_equal<void>;
template<> struct less_equal<void>;

// ??, logical operations
template<class T = void> struct logical_and;
template<class T = void> struct logical_or;
template<class T = void> struct logical_not;
template<> struct logical_and<void>;
template<> struct logical_or<void>;
template<> struct logical_not<void>;

// ??, bitwise operations
template<class T = void> struct bit_and;
template<class T = void> struct bit_or;
template<class T = void> struct bit_xor;
template<class T = void> struct bit_not;
template<> struct bit_and<void>;
template<> struct bit_or<void>;
template<> struct bit_xor<void>;
template<> struct bit_not<void>;

```

```

// ??, function template not_fn
template<class F> unspecified not_fn(F&& f);

// ??, bind

         class BinaryPredicate = equal_to<>>
class boyer_moore_searcher;

template<class RandomAccessIterator,
         class Hash = hash<typename iterator_traits<RandomAccessIterator>::value_type>,
         class BinaryPredicate = equal_to<>>
class boyer_moore_horspool_searcher;

// ??, hash function primary template
template<class T>
struct hash;

// ??, function object binders
template<class T>
inline constexpr bool is_bind_expression_v = is_bind_expression<T>::value;
template<class T>
inline constexpr int is_placeholder_v = is_placeholder<T>::value;
}

```

- <sup>1</sup> [Example: If a C++ program wants to have a by-element addition of two vectors **a** and **b** containing **double** and put the result into **a**, it can do:

```

transform(a.begin(), a.end(), b.begin(), a.begin(), plus<double>());
— end example]

```

- <sup>2</sup> [Example: To negate every element of **a**:

```

transform(a.begin(), a.end(), a.begin(), negate<double>());
— end example]

```

### 23.14.2 Definitions

[func.def]

- <sup>1</sup> The following definitions apply to this Clause:
- <sup>2</sup> A *call signature* is the name of a return type followed by a parenthesized comma-separated list of zero or more argument types.
- <sup>3</sup> A *callable type* is a function object type (??) or a pointer to member.
- <sup>4</sup> A *callable object* is an object of a callable type.
- <sup>5</sup> A *call wrapper type* is a type that holds a callable object and supports a call operation that forwards to that object.
- <sup>6</sup> A *call wrapper* is an object of a call wrapper type.
- <sup>7</sup> A *target object* is the callable object held by a call wrapper.

### 23.14.3 Requirements

[func.require]

- <sup>1</sup> Define *INVOKE(f, t<sub>1</sub>, t<sub>2</sub>, ..., t<sub>N</sub>)* as follows:

- (1.1) — (t<sub>1</sub>.\*f)(t<sub>2</sub>, ..., t<sub>N</sub>) when f is a pointer to a member function of a class T and *is\_base\_of\_v<T, remove\_reference\_t<decltype(t<sub>1</sub>)>>* is true;

- (1.2) —  $(t_1.\text{get}().*f)(t_2, \dots, t_N)$  when  $f$  is a pointer to a member function of a class  $T$  and  $\text{remove_cvref}_t<\text{decltype}(t_1)>$  is a specialization of `reference_wrapper`;
  - (1.3) —  $((*t_1).*f)(t_2, \dots, t_N)$  when  $f$  is a pointer to a member function of a class  $T$  and  $t_1$  does not satisfy the previous two items;
  - (1.4) —  $t_1.*f$  when  $N == 1$  and  $f$  is a pointer to data member of a class  $T$  and  $\text{is_base_of}_v<T, \text{remove_cvref}_t<\text{decltype}(t_1)>>$  is true;
  - (1.5) —  $t_1.\text{get}().*f$  when  $N == 1$  and  $f$  is a pointer to data member of a class  $T$  and  $\text{remove_cvref}_t<\text{decltype}(t_1)>$  is a specialization of `reference_wrapper`;
  - (1.6) —  $(*t_1).*f$  when  $N == 1$  and  $f$  is a pointer to data member of a class  $T$  and  $t_1$  does not satisfy the previous two items;
  - (1.7) —  $f(t_1, t_2, \dots, t_N)$  in all other cases.
- 2 Define  $\text{INVOKER}(f, t_1, t_2, \dots, t_N)$  as `static_cast<void>(INVOKER(f, t1, t2, ..., tN))` if  $R$  is `cv void`, otherwise  $\text{INVOKER}(f, t_1, t_2, \dots, t_N)$  implicitly converted to  $R$ .
- 3 Every call wrapper (??) shall be `MoveConstructible`. A *forwarding call wrapper* is a call wrapper that can be called with an arbitrary argument list and delivers the arguments to the wrapped callable object as references. This forwarding step shall ensure that rvalue arguments are delivered as rvalue references and lvalue arguments are delivered as lvalue references. A *simple call wrapper* is a forwarding call wrapper that is `CopyConstructible` and `CopyAssignable` and whose copy constructor, move constructor, copy assignment operator, and move assignment operator do not throw exceptions. [Note: In a typical implementation forwarding call wrappers have an overloaded function call operator of the form

```
template<class... UnBoundArgs>
R operator()(UnBoundArgs&&... unbound_args) cv-qual;
— end note]
```

#### 23.14.4 Function template `invoke`

[func.invoke]

```
template<class F, class... Args>
invoke_result_t<F, Args...> invoke(F&& f, Args&&... args)
    noexcept(is_nothrow_invocable_v<F, Args...>);
```

1 Returns:  $\text{INVOKER}(\text{std}::\text{forward}<F>(f), \text{std}::\text{forward}<\text{Args}>(args)\dots)$  (??).

#### 23.14.5 Class template `reference_wrapper`

[refwrap]

```
namespace std {
    template<class T> class reference_wrapper {
        public:
            // types
            using type = T;

            // construct/copy/destroy
            template<class U>
                reference_wrapper(U&&) noexcept(see below);
            reference_wrapper(const reference_wrapper& x) noexcept;

            // assignment
            reference_wrapper& operator=(const reference_wrapper& x) noexcept;
```

```

// access
operator T& () const noexcept;
T& get() const noexcept;

// invocation
template<class... ArgTypes>
invoke_result_t<T&, ArgTypes...> operator()(ArgTypes&&...) const;
};

template<class T>
reference_wrapper(T&) -> reference_wrapper<T>;
}

```

<sup>1</sup> `reference_wrapper<T>` is a `CopyConstructible` and `CopyAssignable` wrapper around a reference to an object or function of type `T`.

<sup>2</sup> `reference_wrapper<T>` shall be a trivially copyable type (??).

### 23.14.5.1 `reference_wrapper` construct/copy/destroy

[refwrap.const]

```

template<class U>
reference_wrapper(U&& u) noexcept(see below);

```

<sup>1</sup> *Remarks:* Let `FUN` denote the exposition-only functions

```

void FUN(T&) noexcept;
void FUN(T&&) = delete;

```

This constructor shall not participate in overload resolution unless the expression `FUN(declval<U>())` is well-formed and `is_same_v<decay_t<U>, reference_wrapper>` is `false`. The expression inside `noexcept` is equivalent to `noexcept(FUN(declval<U>()))`.

<sup>2</sup> *Effects:* Creates a variable `r` as if by `T& r = std::forward<U>(u)`, then constructs a `reference_wrapper` object that stores a reference to `r`.

```
reference_wrapper(const reference_wrapper& x) noexcept;
```

<sup>3</sup> *Effects:* Constructs a `reference_wrapper` object that stores a reference to `x.get()`.

### 23.14.5.2 `reference_wrapper` assignment

[refwrap.assign]

```
reference_wrapper& operator=(const reference_wrapper& x) noexcept;
```

<sup>1</sup> *Postconditions:* `*this` stores a reference to `x.get()`.

### 23.14.5.3 `reference_wrapper` access

[refwrap.access]

```
operator T& () const noexcept;
```

<sup>1</sup> *Returns:* The stored reference.

```
T& get() const noexcept;
```

<sup>2</sup> *Returns:* The stored reference.

### 23.14.5.4 `reference_wrapper` invocation

[refwrap.invoke]

```

template<class... ArgTypes>
invoke_result_t<T&, ArgTypes...>

```

```
operator()(ArgTypes&&... args) const;
1   Returns: INVOKE(get(), std::forward<ArgTypes>(args)...). (??)
```

### 23.14.5.5 reference\_wrapper helper functions

[refwrap.helpers]

```
template<class T> reference_wrapper<T> ref(T& t) noexcept;
1   Returns: reference_wrapper<T>(t).

template<class T> reference_wrapper<T> ref(reference_wrapper<T> t) noexcept;
2   Returns: ref(t.get()).

template<class T> reference_wrapper<const T> cref(const T& t) noexcept;
3   Returns: reference_wrapper <const T>(t).

template<class T> reference_wrapper<const T> cref(reference_wrapper<T> t) noexcept;
4   Returns: cref(t.get()).
```

### 23.14.6 Arithmetic operations

[arithmetic.operations]

- 1 The library provides basic function object classes for all of the arithmetic operators in the language (??, ??).

#### 23.14.6.1 Class template plus

[arithmetic.operations.plus]

```
template<class T = void> struct plus {
    constexpr T operator()(const T& x, const T& y) const;
};

constexpr T operator()(const T& x, const T& y) const;
1   Returns: x + y.

template<> struct plus<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) + std::forward<U>(u));

    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) + std::forward<U>(u));
2   Returns: std::forward<T>(t) + std::forward<U>(u).
```

#### 23.14.6.2 Class template minus

[arithmetic.operations.minus]

```
template<class T = void> struct minus {
    constexpr T operator()(const T& x, const T& y) const;
};

constexpr T operator()(const T& x, const T& y) const;
1   Returns: x - y.

template<> struct minus<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) - std::forward<U>(u));
```

```

    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) - std::forward<U>(u));
2     Returns: std::forward<T>(t) - std::forward<U>(u).

```

**23.14.6.3 Class template multiplies**

[arithmetic.operations.multiplies]

```

template<class T = void> struct multiplies {
    constexpr T operator()(const T& x, const T& y) const;
};

constexpr T operator()(const T& x, const T& y) const;
1     Returns: x * y.

template<> struct multiplies<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) * std::forward<U>(u));

    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) * std::forward<U>(u));
2     Returns: std::forward<T>(t) * std::forward<U>(u).

```

**23.14.6.4 Class template divides**

[arithmetic.operations.divides]

```

template<class T = void> struct divides {
    constexpr T operator()(const T& x, const T& y) const;
};

constexpr T operator()(const T& x, const T& y) const;
1     Returns: x / y.

template<> struct divides<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) / std::forward<U>(u));

    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) / std::forward<U>(u));
2     Returns: std::forward<T>(t) / std::forward<U>(u).

```

**23.14.6.5 Class template modulus**

[arithmetic.operations.modulus]

```

template<class T = void> struct modulus {
    constexpr T operator()(const T& x, const T& y) const;
};

```

```

constexpr T operator()(const T& x, const T& y) const;
1      Returns: x % y.

template<> struct modulus<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) % std::forward<U>(u));

    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) % std::forward<U>(u));
2      Returns: std::forward<T>(t) % std::forward<U>(u).

```

**23.14.6.6 Class template negate**

[arithmetic.operations.negate]

```

template<class T = void> struct negate {
    constexpr T operator()(const T& x) const;
};

constexpr T operator()(const T& x) const;
1      Returns: -x.

template<> struct negate<void> {
    template<class T> constexpr auto operator()(T&& t) const
        -> decltype(-std::forward<T>(t));

    using is_transparent = unspecified;
};

template<class T> constexpr auto operator()(T&& t) const
    -> decltype(-std::forward<T>(t));
2      Returns: -std::forward<T>(t).

```

**23.14.7 Comparisons**

[comparisons]

- 1 The library provides basic function object classes for all of the comparison operators in the language (??, ??).
- 2 For templates `less`, `greater`, `less_equal`, and `greater_equal`, the specializations for any pointer type yield a strict total order that is consistent among those specializations and is also consistent with the partial order imposed by the built-in operators `<`, `>`, `<=`, `>=`. [Note: When `a < b` is well-defined for pointers `a` and `b` of type `P`, this implies `(a < b) == less<P>(a, b)`, `(a > b) == greater<P>(a, b)`, and so forth. —end note] For template specializations `less<void>`, `greater<void>`, `less_equal<void>`, and `greater_equal<void>`, if the call operator calls a built-in operator comparing pointers, the call operator yields a strict total order that is consistent among those specializations and is also consistent with the partial order imposed by those built-in operators.

**23.14.7.1 Class template equal\_to**

[comparisons.equal\_to]

```

template<class T = void> struct equal_to {
    constexpr bool operator()(const T& x, const T& y) const;
};

```

```

constexpr bool operator()(const T& x, const T& y) const;
1      Returns: x == y.

template<> struct equal_to<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) == std::forward<U>(u));

    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) == std::forward<U>(u));

2      Returns: std::forward<T>(t) == std::forward<U>(u).

```

### 23.14.7.2 Class template not\_equal\_to [comparisons.not\_equal\_to]

```

template<class T = void> struct not_equal_to {
    constexpr bool operator()(const T& x, const T& y) const;
};

constexpr bool operator()(const T& x, const T& y) const;
1      Returns: x != y.

template<> struct not_equal_to<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) != std::forward<U>(u));

    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) != std::forward<U>(u));

2      Returns: std::forward<T>(t) != std::forward<U>(u).

```

### 23.14.7.3 Class template greater [comparisons.greater]

```

template<class T = void> struct greater {
    constexpr bool operator()(const T& x, const T& y) const;
};

constexpr bool operator()(const T& x, const T& y) const;
1      Returns: x > y.

template<> struct greater<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) > std::forward<U>(u));

    using is_transparent = unspecified;
};

```

```
template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) > std::forward<U>(u));
2     Returns: std::forward<T>(t) > std::forward<U>(u).
```

**23.14.7.4 Class template less**

[comparisons.less]

```
template<class T = void> struct less {
    constexpr bool operator()(const T& x, const T& y) const;
};

constexpr bool operator()(const T& x, const T& y) const;
1     Returns: x < y.

template<> struct less<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) < std::forward<U>(u));

    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) < std::forward<U>(u));
2     Returns: std::forward<T>(t) < std::forward<U>(u).
```

**23.14.7.5 Class template greater\_equal**

[comparisons.greater\_equal]

```
template<class T = void> struct greater_equal {
    constexpr bool operator()(const T& x, const T& y) const;
};

constexpr bool operator()(const T& x, const T& y) const;
1     Returns: x >= y.

template<> struct greater_equal<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) >= std::forward<U>(u));

    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) >= std::forward<U>(u));
2     Returns: std::forward<T>(t) >= std::forward<U>(u).
```

**23.14.7.6 Class template less\_equal**

[comparisons.less\_equal]

```
template<class T = void> struct less_equal {
    constexpr bool operator()(const T& x, const T& y) const;
};

constexpr bool operator()(const T& x, const T& y) const;
1     Returns: x <= y.
```

```

template<> struct less_equal<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) <= std::forward<U>(u));

    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) <= std::forward<U>(u));
2     Returns: std::forward<T>(t) <= std::forward<U>(u).

```

### 23.14.8 Logical operations

[logical.operations]

1 The library provides basic function object classes for all of the logical operators in the language (??, ??, ??).

#### 23.14.8.1 Class template logical\_and

[logical.operations.and]

```

template<class T = void> struct logical_and {
    constexpr bool operator()(const T& x, const T& y) const;
};

constexpr bool operator()(const T& x, const T& y) const;
1     Returns: x && y.

template<> struct logical_and<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) && std::forward<U>(u));

    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) && std::forward<U>(u));
2     Returns: std::forward<T>(t) && std::forward<U>(u).

```

#### 23.14.8.2 Class template logical\_or

[logical.operations.or]

```

template<class T = void> struct logical_or {
    constexpr bool operator()(const T& x, const T& y) const;
};

constexpr bool operator()(const T& x, const T& y) const;
1     Returns: x || y.

template<> struct logical_or<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) || std::forward<U>(u));

    using is_transparent = unspecified;
};

```

```
template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) || std::forward<U>(u));
2     Returns: std::forward<T>(t) || std::forward<U>(u).
```

**23.14.8.3 Class template logical\_not**

[logical.operations.not]

```
template<class T = void> struct logical_not {
    constexpr bool operator()(const T& x) const;
};

constexpr bool operator()(const T& x) const;
1     Returns: !x.

template<> struct logical_not<void> {
    template<class T> constexpr auto operator()(T&& t) const
        -> decltype(!std::forward<T>(t));

    using is_transparent = unspecified;
};

template<class T> constexpr auto operator()(T&& t) const
    -> decltype(!std::forward<T>(t));
2     Returns: !std::forward<T>(t).
```

**23.14.9 Bitwise operations**

[bitwise.operations]

- 1 The library provides basic function object classes for all of the bitwise operators in the language (??, ??, ??, ??).

**23.14.9.1 Class template bit\_and**

[bitwise.operations.and]

```
template<class T = void> struct bit_and {
    constexpr T operator()(const T& x, const T& y) const;
};

constexpr T operator()(const T& x, const T& y) const;
1     Returns: x & y.

template<> struct bit_and<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) & std::forward<U>(u));

    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) & std::forward<U>(u));
2     Returns: std::forward<T>(t) & std::forward<U>(u).
```

**23.14.9.2 Class template bit\_or**

[bitwise.operations.or]

```
template<class T = void> struct bit_or {
    constexpr T operator()(const T& x, const T& y) const;
```

```

};

constexpr T operator()(const T& x, const T& y) const;

1      Returns: x | y.

template<> struct bit_or<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) | std::forward<U>(u));

    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) | std::forward<U>(u));

2      Returns: std::forward<T>(t) | std::forward<U>(u).

```

**23.14.9.3 Class template bit\_xor**

[bitwise.operations.xor]

```

template<class T = void> struct bit_xor {
    constexpr T operator()(const T& x, const T& y) const;
};

constexpr T operator()(const T& x, const T& y) const;

1      Returns: x ^ y.

template<> struct bit_xor<void> {
    template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
        -> decltype(std::forward<T>(t) ^ std::forward<U>(u));

    using is_transparent = unspecified;
};

template<class T, class U> constexpr auto operator()(T&& t, U&& u) const
    -> decltype(std::forward<T>(t) ^ std::forward<U>(u));

2      Returns: std::forward<T>(t) ^ std::forward<U>(u).

```

**23.14.9.4 Class template bit\_not**

[bitwise.operations.not]

```

template<class T = void> struct bit_not {
    constexpr T operator()(const T& x) const;
};

constexpr T operator()(const T& x) const;

1      Returns: ~x.

template<> struct bit_not<void> {
    template<class T> constexpr auto operator()(T&& t) const
        -> decltype(~std::forward<T>(t));

    using is_transparent = unspecified;
};

```

```
template<class T> constexpr auto operator()(T&&) const
-> decltype(~std::forward<T>(t));
```

2     *Returns:* ~std::forward<T>(t).

### 23.14.10 Function template not\_fn

[func.not\_fn]

```
template<class F> unspecified not_fn(F&& f);
```

1     *Effects:* Equivalent to: return call\_wrapper(std::forward<F>(f)); where call\_wrapper is an exposition only class defined as follows:

```
class call_wrapper {
    using FD = decay_t<F>;
    FD fd;

    explicit call_wrapper(F&& f);

public:
    call_wrapper(call_wrapper&&) = default;
    call_wrapper(const call_wrapper&) = default;

    template<class... Args>
    auto operator()(Args&&...) &
-> decltype(!declval<invoke_result_t<FD&, Args...>>());
```

```
template<class... Args>
auto operator()(Args&&...) const&
-> decltype(!declval<invoke_result_t<const FD&, Args...>>());
```

```
template<class... Args>
auto operator()(Args&&...) &&
-> decltype(!declval<invoke_result_t<FD, Args...>>());
```

```
template<class... Args>
auto operator()(Args&&...) const&&
-> decltype(!declval<invoke_result_t<const FD, Args...>>());
```

};

explicit call\_wrapper(F&& f);

2     *Requires:* FD shall satisfy the requirements of MoveConstructible. is\_constructible\_v<FD, F> shall be true. fd shall be a callable object (??).

3     *Effects:* Initializes fd from std::forward<F>(f).

4     *Throws:* Any exception thrown by construction of fd.

```
template<class... Args>
auto operator()(Args&&... args) &
-> decltype(!declval<invoke_result_t<FD&, Args...>>());
```

```
template<class... Args>
auto operator()(Args&&... args) const&
```

```

-> decltype(!declval<invoke_result_t<const FD&, Args...>>());
5   Effects: Equivalent to:
      return !INVOKE(fd, std::forward<Args>(args)...);           // see ??

template<class... Args>
auto operator()(Args&&... args) &&
-> decltype(!declval<invoke_result_t<FD, Args...>>());
template<class... Args>
auto operator()(Args&&... args) const&&
-> decltype(!declval<invoke_result_t<const FD, Args...>>());
6   Effects: Equivalent to:
      return !INVOKE(std::move(fd), std::forward<Args>(args)...); // see ??

```

### 23.14.11 Function object binders

[func.bind]

- <sup>1</sup> This subclause describes a uniform mechanism for binding arguments of callable objects.

#### 23.14.11.1 Class template `is_bind_expression`

[func.bind.isbind]

```

namespace std {
    template<class T> struct is_bind_expression; // see below
}

```

- <sup>1</sup> The class template `is_bind_expression` can be used to detect function objects generated by `bind`. The function template `bind` uses `is_bind_expression` to detect subexpressions.
- <sup>2</sup> Instantiations of the `is_bind_expression` template shall meet the `UnaryTypeTrait` requirements (??). The implementation shall provide a definition that has a base characteristic of `true_type` if `T` is a type returned from `bind`, otherwise it shall have a base characteristic of `false_type`. A program may specialize this template for a user-defined type `T` to have a base characteristic of `true_type` to indicate that `T` should be treated as a subexpression in a `bind` call.

#### 23.14.11.2 Class template `is_placeholder`

[func.bind.isplace]

```

namespace std {
    template<class T> struct is_placeholder; // see below
}

```

- <sup>1</sup> The class template `is_placeholder` can be used to detect the standard placeholders `_1`, `_2`, and so on. The function template `bind` uses `is_placeholder` to detect placeholders.
- <sup>2</sup> Instantiations of the `is_placeholder` template shall meet the `UnaryTypeTrait` requirements (??). The implementation shall provide a definition that has the base characteristic of `integral_constant<int, J>` if `T` is the type of `std::placeholders::_J`, otherwise it shall have a base characteristic of `integral_constant<int, 0>`. A program may specialize this template for a user-defined type `T` to have a base characteristic of `integral_constant<int, N>` with `N > 0` to indicate that `T` should be treated as a placeholder type.

#### 23.14.11.3 Function template `bind`

[func.bind.bind]

- <sup>1</sup> In the text that follows:

- (1.1) — `FD` is the type `decay_t<F>`,
- (1.2) — `fd` is an lvalue of type `FD` constructed from `std::forward<F>(f)`,

- (1.3) —  $T_i$  is the  $i^{\text{th}}$  type in the template parameter pack `BoundArgs`,
- (1.4) —  $TD_i$  is the type `decay_t<Ti>`,
- (1.5) —  $t_i$  is the  $i^{\text{th}}$  argument in the function parameter pack `bound_args`,
- (1.6) —  $td_i$  is an lvalue of type  $TD_i$  constructed from `std::forward<Ti>(ti)`,
- (1.7) —  $U_j$  is the  $j^{\text{th}}$  deduced type of the `UnBoundArgs&&... bound_args` parameter of the forwarding call wrapper, and
- (1.8) —  $u_j$  is the  $j^{\text{th}}$  argument associated with  $U_j$ .

```
template<class F, class... BoundArgs>
unspecified bind(F&& f, BoundArgs&&... bound_args);
```

2 *Requires:* `is_constructible_v<FD, F>` shall be `true`. For each  $T_i$  in `BoundArgs`, `is_constructible_v<TDi, Ti>` shall be `true`. `(INVOKE(fd, w1, w2, ..., wN)` (??) shall be a valid expression for some values  $w_1, w_2, \dots, w_N$ , where  $N$  has the value `sizeof... (bound_args)`. The cv-qualifiers `cv` of the call wrapper `g`, as specified below, shall be neither `volatile` nor `const volatile`.

3 *Returns:* A forwarding call wrapper `g` (??). The effect of `g(u1, u2, ..., uM)` shall be

`(INVOKE(fd, std::forward<V1>(v1), std::forward<V2>(v2), ..., std::forward<VN>(vN))`

where the values and types of the bound arguments  $v_1, v_2, \dots, v_N$  are determined as specified below. The copy constructor and move constructor of the forwarding call wrapper shall throw an exception if and only if the corresponding constructor of `FD` or of any of the types  $TD_i$  throws an exception.

4 *Throws:* Nothing unless the construction of `fd` or of one of the values  $td_i$  throws an exception.

5 *Remarks:* The return type shall satisfy the requirements of `MoveConstructible`. If all of `FD` and  $TD_i$  satisfy the requirements of `CopyConstructible`, then the return type shall satisfy the requirements of `CopyConstructible`. [Note: This implies that all of `FD` and  $TD_i$  are `MoveConstructible`. —end note]

```
template<class R, class F, class... BoundArgs>
unspecified bind(F&& f, BoundArgs&&... bound_args);
```

6 *Requires:* `is_constructible_v<FD, F>` shall be `true`. For each  $T_i$  in `BoundArgs`, `is_constructible_v<TDi, Ti>` shall be `true`. `(INVOKE(fd, w1, w2, ..., wN)` shall be a valid expression for some values  $w_1, w_2, \dots, w_N$ , where  $N$  has the value `sizeof... (bound_args)`. The cv-qualifiers `cv` of the call wrapper `g`, as specified below, shall be neither `volatile` nor `const volatile`.

7 *Returns:* A forwarding call wrapper `g` (??). The effect of `g(u1, u2, ..., uM)` shall be

`(INVOKE<R>(fd, std::forward<V1>(v1), std::forward<V2>(v2), ..., std::forward<VN>(vN))`

where the values and types of the bound arguments  $v_1, v_2, \dots, v_N$  are determined as specified below. The copy constructor and move constructor of the forwarding call wrapper shall throw an exception if and only if the corresponding constructor of `FD` or of any of the types  $TD_i$  throws an exception.

8 *Throws:* Nothing unless the construction of `fd` or of one of the values  $td_i$  throws an exception.

9 *Remarks:* The return type shall satisfy the requirements of `MoveConstructible`. If all of `FD` and  $TD_i$  satisfy the requirements of `CopyConstructible`, then the return type shall satisfy the requirements of `CopyConstructible`. [Note: This implies that all of `FD` and  $TD_i$  are `MoveConstructible`. —end note]

10 The values of the *bound arguments*  $v_1, v_2, \dots, v_N$  and their corresponding types  $V_1, V_2, \dots, V_N$  depend on the types  $TD_i$  derived from the call to `bind` and the cv-qualifiers `cv` of the call wrapper `g` as follows:

- (10.1) — if  $\text{TD}_i$  is `reference_wrapper<T>`, the argument is  $\text{td}_i.\text{get}()$  and its type  $V_i$  is  $T\&;$
- (10.2) — if the value of `is_bind_expression_v<TD_i>` is `true`, the argument is  $\text{td}_i(\text{std}:\text{forward}<U_j>(\text{u}_j) \dots)$  and its type  $V_i$  is `invoke_result_t<TD_i cv &, U_j...>&&;`
- (10.3) — if the value  $j$  of `is_placeholder_v<TD_i>` is not zero, the argument is `std::forward<U_j>(\text{u}_j)` and its type  $V_i$  is  $U_j\&&;$
- (10.4) — otherwise, the value is  $\text{td}_i$  and its type  $V_i$  is  $\text{TD}_i\ cv\ \&.$

#### 23.14.11.4 Placeholders

[func.bind.place]

```
namespace std::placeholders {
    // M is the implementation-defined number of placeholders
    see below _1;
    see below _2;
    .
    .
    .
    see below _M;
}
```

- <sup>1</sup> All placeholder types shall be `DefaultConstructible` and `CopyConstructible`, and their default constructors and copy/move constructors shall not throw exceptions. It is implementation-defined whether placeholder types are `CopyAssignable`. `CopyAssignable` placeholders' copy assignment operators shall not throw exceptions.
- <sup>2</sup> Placeholders should be defined as:

```
inline constexpr unspecified _1{};
```

If they are not, they shall be declared as:

```
extern unspecified _1;
```

#### 23.14.12 Function template `mem_fn`

[func.memfn]

```
template<class R, class T> unspecified mem_fn(R T::* pm) noexcept;
```

- <sup>1</sup> *Returns*: A simple call wrapper (??) `fn` such that the expression `fn(t, a2, ..., aN)` is equivalent to `INVOKE(pm, t, a2, ..., aN)` (??).

#### 23.14.13 Polymorphic function wrappers

[func.wrap]

- <sup>1</sup> This subclause describes a polymorphic wrapper class that encapsulates arbitrary callable objects.

##### 23.14.13.1 Class `bad_function_call`

[func.wrap.badcall]

- <sup>1</sup> An exception of type `bad_function_call` is thrown by `function::operator()` (??) when the function wrapper object has no target.

```
namespace std {
    class bad_function_call : public exception {
        public:
            // ??, constructor
            bad_function_call() noexcept;
    };
}
```

**23.14.13.1.1 bad\_function\_call constructor**

[func.wrap.badcall.const]

```
bad_function_call() noexcept;

1   Effects: Constructs a bad_function_call object.
```

```
2   Postconditions: what() returns an implementation-defined NTBS.
```

**23.14.13.2 Class template function**

[func.wrap.func]

```
namespace std {

    template<class> class function; // not defined

    template<class R, class... ArgTypes>
    class function<R(ArgTypes...)> {
        public:
            using result_type = R;

            // ??, construct/copy/destroy
            function() noexcept;
            function(nullptr_t) noexcept;
            function(const function&);
            function(function&&);

            template<class F> function(F);

            function& operator=(const function&);
            function& operator=(function&&);
            function& operator=(nullptr_t) noexcept;
            template<class F> function& operator=(F&&);
            template<class F> function& operator=(reference_wrapper<F>) noexcept;

            ~function();

            // ??, function modifiers
            void swap(function&) noexcept;

            // ??, function capacity
            explicit operator bool() const noexcept;

            // ??, function invocation
            R operator()(ArgTypes...) const;

            // ??, function target access
            const type_info& target_type() const noexcept;
            template<class T> T* target() noexcept;
            template<class T> const T* target() const noexcept;
    };

    template<class R, class... ArgTypes>
    function(R(*)(ArgTypes...)) -> function<R(ArgTypes...)>;

    template<class F> function(F) -> function<see below>;
}
```

```
// ??, Null pointer comparisons
template<class R, class... ArgTypes>
    bool operator==(const function<R(ArgTypes...)>&, nullptr_t) noexcept;

template<class R, class... ArgTypes>
    bool operator==(nullptr_t, const function<R(ArgTypes...)>&) noexcept;

template<class R, class... ArgTypes>
    bool operator!=(const function<R(ArgTypes...)>&, nullptr_t) noexcept;

template<class R, class... ArgTypes>
    bool operator!=(nullptr_t, const function<R(ArgTypes...)>&) noexcept;

// ??, specialized algorithms
template<class R, class... ArgTypes>
    void swap(function<R(ArgTypes...)>&, function<R(ArgTypes...)>&) noexcept;
}
```

- <sup>1</sup> The `function` class template provides polymorphic wrappers that generalize the notion of a function pointer. Wrappers can store, copy, and call arbitrary callable objects (??), given a call signature (??), allowing functions to be first-class objects.
- <sup>2</sup> A callable type (??) `F` is *Lvalue-Callable* for argument types `ArgTypes` and return type `R` if the expression `INVOKE<R>(declval<F&>(), declval<ArgTypes>()...)`, considered as an unevaluated operand (??), is well-formed (??).
- <sup>3</sup> The `function` class template is a call wrapper (??) whose call signature (??) is `R(ArgTypes...)`.
- <sup>4</sup> [Note: The types deduced by the deduction guides for `function` may change in future versions of this International Standard. —end note]

### 23.14.13.2.1 function construct/copy/destroy

[func.wrap.func.con]

- ```
function() noexcept;
```
- <sup>1</sup> *Postconditions:* `!*this`.

```
function(nullptr_t) noexcept;
```

  - <sup>2</sup> *Postconditions:* `!*this`.

```
function(const function& f);
```

  - <sup>3</sup> *Postconditions:* `!*this` if `!f`; otherwise, `*this` targets a copy of `f.target()`.
  - <sup>4</sup> *Throws:* Shall not throw exceptions if `f`'s target is a specialization of `reference_wrapper` or a function pointer. Otherwise, may throw `bad_alloc` or any exception thrown by the copy constructor of the stored callable object. [Note: Implementations should avoid the use of dynamically allocated memory for small callable objects, for example, where `f`'s target is an object holding only a pointer or reference to an object and a member function pointer. —end note]
- ```
function(function&& f);
```
- <sup>5</sup> *Postconditions:* If `!f`, `*this` has no target; otherwise, the target of `*this` is equivalent to the target of `f` before the construction, and `f` is in a valid state with an unspecified value.

6        *Throws:* Shall not throw exceptions if `f`'s target is a specialization of `reference_wrapper` or a function pointer. Otherwise, may throw `bad_alloc` or any exception thrown by the copy or move constructor of the stored callable object. [ *Note:* Implementations should avoid the use of dynamically allocated memory for small callable objects, for example, where `f`'s target is an object holding only a pointer or reference to an object and a member function pointer. — *end note* ]

```
template<class F> function(F f);
```

7        *Requires:* `F` shall be `CopyConstructible`.

8        *Remarks:* This constructor template shall not participate in overload resolution unless `F` is `LvalueCallable` (??) for argument types `ArgTypes...` and return type `R`.

9        *Postconditions:* `!*this` if any of the following hold:

(9.1)     — `f` is a null function pointer value.

(9.2)     — `f` is a null member pointer value.

(9.3)     — `F` is an instance of the `function` class template, and `!f`.

10      Otherwise, `*this` targets a copy of `f` initialized with `std::move(f)`. [ *Note:* Implementations should avoid the use of dynamically allocated memory for small callable objects, for example, where `f` is an object holding only a pointer or reference to an object and a member function pointer. — *end note* ]

11      *Throws:* Shall not throw exceptions when `f` is a function pointer or a `reference_wrapper<T>` for some `T`. Otherwise, may throw `bad_alloc` or any exception thrown by `F`'s copy or move constructor.

```
template<class F> function(F -> function<see below>);
```

12      *Remarks:* This deduction guide participates in overload resolution only if `&F::operator()` is well-formed when treated as an unevaluated operand. In that case, if `decltype(&F::operator())` is of the form `R(G::*) (A...)` *cv* `&opt noexcept opt` for a class type `G`, then the deduced type is `function<R(A...)>`.

13      [ *Example:*

```
void f() {
    int i{5};
    function g = [&](double) { return i; }; // deduces function<int(double)>
}
```

— *end example* ]

```
function& operator=(const function& f);
```

14      *Effects:* As if by `function(f).swap(*this)`;

15      *Returns:* `*this`.

```
function& operator=(function&& f);
```

16      *Effects:* Replaces the target of `*this` with the target of `f`.

17      *Returns:* `*this`.

```
function& operator=(nullptr_t) noexcept;
```

18      *Effects:* If `*this != nullptr`, destroys the target of `this`.

19      *Postconditions:* `!(*this)`.

20      *Returns:* `*this`.

```

template<class F> function& operator=(F&& f);

21   Effects: As if by: function(std::forward<F>(f)).swap(*this);

22   Returns: *this.

23   Remarks: This assignment operator shall not participate in overload resolution unless decay_t<F> is
Lvalue-Callable (??) for argument types ArgTypes... and return type R.

template<class F> function& operator=(reference_wrapper<F> f) noexcept;

24   Effects: As if by: function(f).swap(*this);

25   Returns: *this.

~function();

26   Effects: If *this != nullptr, destroys the target of this.

```

**23.14.13.2.2 function modifiers**

[func.wrap.func.mod]

```
void swap(function& other) noexcept;
```

1 Effects: Interchanges the targets of \*this and other.

**23.14.13.2.3 function capacity**

[func.wrap.func.cap]

```
explicit operator bool() const noexcept;
```

1 Returns: true if \*this has a target, otherwise false.

**23.14.13.2.4 function invocation**

[func.wrap.func.inv]

```
R operator()(ArgTypes... args) const;
```

1 Returns: *INVOKE*<R>(f, std::forward<ArgTypes>(args)...)(??), where f is the target object (??) of \*this.

2 Throws: *bad\_function\_call* if !\*this; otherwise, any exception thrown by the wrapped callable object.

**23.14.13.2.5 function target access**

[func.wrap.func.targ]

```
const type_info& target_type() const noexcept;
```

1 Returns: If \*this has a target of type T, typeid(T); otherwise, typeid(void).

```
template<class T>      T* target() noexcept;
template<class T> const T* target() const noexcept;
```

2 Returns: If target\_type() == typeid(T) a pointer to the stored function target; otherwise a null pointer.

**23.14.13.2.6 null pointer comparison functions**

[func.wrap.func.nullptr]

```

template<class R, class... ArgTypes>
bool operator==(const function<R(ArgTypes...)>& f, nullptr_t) noexcept;
template<class R, class... ArgTypes>
bool operator==(nullptr_t, const function<R(ArgTypes...)>& f) noexcept;

```

1 Returns: !f.

```
template<class R, class... ArgTypes>
    bool operator!=(const function<R(ArgTypes...)>& f, nullptr_t) noexcept;
template<class R, class... ArgTypes>
    bool operator!=(nullptr_t, const function<R(ArgTypes...)>& f) noexcept;
```

2       >Returns: (bool)f.

**23.14.13.2.7 specialized algorithms**

[func.wrap.func.alg]

```
template<class R, class... ArgTypes>
    void swap(function<R(ArgTypes...)>& f1, function<R(ArgTypes...)>& f2) noexcept;
```

1       >Effects: As if by: f1.swap(f2);

**23.14.14 Searchers**

[func.search]

- 1 This subclause provides function object types (??) for operations that search for a sequence [pat\_first, pat\_last) in another sequence [first, last) that is provided to the object's function call operator. The first sequence (the pattern to be searched for) is provided to the object's constructor, and the second (the sequence to be searched) is provided to the function call operator.
- 2 Each specialization of a class template specified in this subclause ?? shall meet the **CopyConstructible** and **CopyAssignable** requirements. Template parameters named

- (2.1) — **ForwardIterator**,
- (2.2) — **ForwardIterator1**,
- (2.3) — **ForwardIterator2**,
- (2.4) — **RandomAccessIterator**,
- (2.5) — **RandomAccessIterator1**,
- (2.6) — **RandomAccessIterator2**, and
- (2.7) — **BinaryPredicate**

of templates specified in this subclause ?? shall meet the same requirements and semantics as specified in ??.  
Template parameters named **Hash** shall meet the requirements as specified in ??.

- 3 The Boyer-Moore searcher implements the Boyer-Moore search algorithm. The Boyer-Moore-Horspool searcher implements the Boyer-Moore-Horspool search algorithm. In general, the Boyer-Moore searcher will use more memory and give better runtime performance than Boyer-Moore-Horspool.

**23.14.14.1 Class template default\_searcher**

[func.search.default]

```
template<class ForwardIterator1, class BinaryPredicate = equal_to<>>
    class default_searcher {
    public:
        default_searcher(ForwardIterator1 pat_first, ForwardIterator1 pat_last,
                         BinaryPredicate pred = BinaryPredicate());
        template<class ForwardIterator2>
        pair<ForwardIterator2, ForwardIterator2>
        operator()(ForwardIterator2 first, ForwardIterator2 last) const;

    private:
        ForwardIterator1 pat_first_;                   // exposition only
```

```

    ForwardIterator1 pat_last_;           // exposition only
    BinaryPredicate pred_;              // exposition only
};

default_searcher(ForwardIterator pat_first, ForwardIterator pat_last,
                 BinaryPredicate pred = BinaryPredicate());

```

1     *Effects:* Constructs a `default_searcher` object, initializing `pat_first_` with `pat_first`, `pat_last_` with `pat_last`, and `pred_` with `pred`.

2     *Throws:* Any exception thrown by the copy constructor of `BinaryPredicate` or `ForwardIterator1`.

```

template<class ForwardIterator2>
pair<ForwardIterator2, ForwardIterator2>
operator()(ForwardIterator2 first, ForwardIterator2 last) const;

3     Effects: Returns a pair of iterators i and j such that
(3.1)   — i == search(first, last, pat_first_, pat_last_, pred_), and
(3.2)   — if i == last, then j == last, otherwise j == next(i, distance(pat_first_, pat_last_)).

```

#### 23.14.14.2 Class template `boyer_moore_searcher`

[func.search.bm]

```

template<class RandomAccessIterator1,
         class Hash = hash<typename iterator_traits<RandomAccessIterator1>::value_type>,
         class BinaryPredicate = equal_to<>>
class boyer_moore_searcher {
public:
    boyer_moore_searcher(RandomAccessIterator1 pat_first,
                          RandomAccessIterator1 pat_last,
                          Hash hf = Hash(),
